Electric Power on a Holiday.—One of the most charming days this summer has seen was vouchsafed by the clerk of the weather last Saturday for the annual outing of the employés of the General Electric Traction and Power Company. A party of 40 or 50 met at Waterloo and steamed to Hampton Court, where the "largest electric boat in the world"—the "Viscountess Bury," well known to visitors to the Thames—was waiting to take them up the river. The men swarmed in happy groups on the roof of this palatial vessel, which has carried dukes, millionaires, editors, and celebrities galore, and the run was begun with easy motion in the lovely warm air of the brilliant September morning, showing up in a set of glorious pictures the changing views of the banks of the upper Thames. A short stop was made at the Immisch electric charging station at Tagg's Island, where a photograph of the group was taken by one of the party present, and then a clean run was made past a most interesting panorama, by quaint Chertsey, picturesque Shepperton, up to the Pack-house at Staines, where, after light refreshment and more photography, the party returned on boat for the run back. A thoroughly enjoyable outing, due to the initiative of Mr. Immisch, and well carried out by the secretary, Mr Smith, aided by Mr Coppin, was brought to a close by dinner and toasts at The Greyhound, Hampton Court.

Aluminium Boats.—Aluminium seems growing in favour as a matter for launches on account of its light weight, great strength, and silvery appearance. A yacht of aluminium was lately launched on Lake Zurich's "fair waters" by Messrs. Escher, Wyss, and Co. This yacht was built to the order of Mr. Nobel, a Swedish gentleman, for cruising in the Mediterranean. The aluminium was produced by the Aluminium Works of Schaffhausen, and it really seems that the material has a useful future in this direction. The boat is 40ft. long with 6ft. beam, carries 20 passengers, though weighing only 1.6 tons as against three tons for an ordinary yacht of this size. It is fitted with a 6-h.p. naphtha engine, and made easily 10 miles an hour. While electric launches are so popular on the Thames, the originality of an aluminium launch of this description would, we should think, prove a great attraction, and it might be worth while for one of the firms interested in this class of boat to build on commission an aluminium boat for "up the river" trips. We learn that Messrs. Escher, Wyss, and Co. are building another boat of this description specially constructed for overland transportation, for use on the African lakes, a purpose for which the aluminium boat is peculiarly fitted on account of its lightness. The bright appearance of these boats was much admired at Frankfort last year, and their wide extension is evidently only a matter of time.

The Electro-Harmonic Society.—The meeting of friends, conjoined with sweet harmony, is once more promised to the members of the Electro-Harmonic Society in the first smoking concert of the season, which takes place on Friday, September 30, at the St. James's Hall Restaurant (Banquet-room), at 8 o'clock. Artistes: Mr James Brown, Mr. Albert James, Mr. Arthur Thompson, Mr. R. Hilton; violoncello, Mr. W. C. Hann; pianoforte, Mr. Alfred E. Izard; humorous selections, Mr James Kift; musical directors, Mr. T. E. Gatehouse and Mr. Alfred Izard. Programme, Part I: Part song, "The Young Musician" (F Kucken), song, "The Message" (Blumenthal), Mr. Albert James; song, "Quaff with Me the Purple Wine" (Shield, 1784-1829), Mr. Robert Hilton; pianoforte solo, "Prelude and Fugue in E minor" (Mendelssohn), Mr. Alfred Izard; glee, "Songs should breathe" (W. H. Cummings); violoncello solos, (a) "Feuillet d'Album," (b) "Elfentanz" (Popper), Mr W. C. Hann; air (semele), "Where 'ere You Walk" (Handel), Mr Arthur Thompson; humorous song, "Wait till the Luck comes round" (Beney), Mr. James Kift. Part II: Glee, "The Countryman's Song" (W. Horsley); violoncello solo, "Caprice Hongroise" (Dunkler), Mr. W. C. Hann; song, "Maid of Athens" (H. R. Allen), Mr Albert James; song, "The Friar's Song" ("Ivanhoe," Sullivan), Mr. Robert Hilton; pianoforte solo, "Mazurk" (Op. 103), (B. Godard), Mr. Alfred Izard; song, "Mefisto" (Gounod), Mr. Arthur Thompson; humorous song, "The Johnnie's Serenade" (Chevalier), Mr James Kift.

Gas v. Electricity.—Ever since the introduction of electric light, gas companies have looked on the new industry with a certain measure of good-humoured contempt, having considered that it was a toy and would always have to be supplemented by gas. One of the first gas companies to seriously feel the competition of electricity has been the gas company of Carlow, in Ireland, which town Messrs. J. E. H. Gordon and Co., Limited, of 11, Pall mall, have been lighting for the last 14 months. Week by week more lights have been taken on, and at the present moment nearly one quarter of the total revenue of the gas company has been transferred to Messrs. Gordon for payment of electricity. Last night the gas company issued a circular to the inhabitants of Carlow, informing them that any persons using electricity would be at once cut off from the gas mains. Immediately on receipt of a copy of this circular, Messrs. Gordon telegraphed to the town clerk of Carlow, and to their office in Carlow, as follows: "Town Clerk, Carlow,—Please inform inhabitants, whom we hear the gas company are endeavouring to deprive of light, that we are prepared to supply the whole town, and will immediately send over all necessary materials and men to save the town from incon-

venience.—(Signed) Gordon, London." "To Gordon and Co., Carlow,—Use every effort to supply all inhabitants coerced by gas company, and requisition at once for all men and materials required.—(Signed) Gordon, London." A large staff of extra men and all the necessary materials for wiring the rest of the town and for enlarging the plant are being sent over as rapidly as possible. It is to be hoped that the action of the Carlow Gas Company will be followed by other gas companies, and thus will hasten the final displacement of gas by electricity for the illumination of shops and private houses.

Sheffield.—The *Sheffield Independent*, the Liberal newspaper of the cutlery town, has just taken unto itself new and palatial offices in Fargate, and issues a special descriptive number, in which the manifold departments of a large and flourishing provincial daily paper are interestingly shown. The machine-room is 100ft. by 53ft., and contains two Victory machines capable of printing 16,000 copies an hour, and one of the newest forms of the Hoe machine, which will print, fold, and deliver at 24,000 an hour. Two engines, of 145 h.p., built by Shardlow, of Sheffield, stand at one end. They are connected by friction clutches, so that either engine can be started or stopped without affecting the speed of the main shaft. This is of importance as regards the electric light, with which the entire premises are fitted. The installation is as efficient and complete as money and care could make it, and is the work of the Manchester Edison-Swan Company. The dynamo is of the Edison-Hopkinson type, of a capacity equal to 400 16-c.p. lamps, a capacity somewhat above that at present required. The installation now consists of about 350 16-c.p. lamps, and three arc lamps for illumination of the entrance and roadway. Every room in the building is lighted by electricity, and gas is only to be resorted to in case of stoppage. The use of the telephone in the new office is considerable. The *Independent* was the first subscriber to Messrs. Tasker's exchange, and later joined the National system, which they have often found very useful in communicating to different towns. They have besides their own system of telephones throughout the offices, supplied by Messrs. Tasker, each instrument being fitted with its own switchboard for simple and easy intercommunication. Altogether the new offices are exceedingly well fitted up, replete with all the newest improvements, and are a credit to the enterprising proprietors, Messrs. Leader and Son.

Dundee.—The question of the cost of the lighting in Dundee is now exercising the minds of the inhabitants. Messrs. J. P. Smith and Sons, who have had a private installation of their own running for several years, consider from their experience it will cost nearly double the price of gas. The firm have 226 lamps of 16 c.p., and measuring the current taken they find at 5d. a unit their lighting would come to 5s. an hour. But supplying their own motive power they are able to produce the light at 3¼d. a unit, including gas and oil for engine as well as interest on plant and fittings. The work of laying the cast-iron pipes in the streets of the city is proceeding apace, and it is expected that everthing will be in readiness for supplying the light to all within the prescribed area about the end of November. The mains, composed of copper cables of different sectional areas, insulated by vulcanised rubber, will be laid in the pipes and culverts along the route mapped out by the Commissioners. The culverts, which are 4in. deep at the bottom and 6in. wide at the side, are being built of concrete. There are altogether nearly 3,150ft. of culvert. Some of these will contain three copper strips each, and others seven copper strips. The insulators in the culverts will be 6ft. apart. Arrangements are to be made to carry off all water that may gather in the culverts by giving therein a fall of ½in. per yard; in the event of a water-pipe bursting above them damage will be prevented by placing at each box a Buchan trap connected with the sewer, while an escape of gas into the culvert is to be provided against by ventilators placed at a higher level. Those parts of the route not supplied with culverts—which are only necessary in connection with the "feeders"—have cast-iron pipes with mains laid in trenches. As the installation is to be on the three-wire system, three cables of varying diameters and lengths are placed in each pipe. At the corners of streets junction-boxes will be provided for the purpose of drawing in the cables. The distributing mains are being laid down by the India Rubber Company, and the feeders by the Callender Company, the former consisting of insulated cables drawn into cast-iron pipes, the latter of copper strips laid on porcelain insulators in a concrete culvert.

Electric Cooking. — Messrs. Crompton and Co., Limited, are giving close attention to the development of the use of electricity for domestic purposes, including cooking, and in order to bring the advantages of their apparatus before the public, they are showing it at various exhibitions at the present time. The latest exhibit is at the Health Exhibition, Portsmouth, in connection with the Sanitary Congress, where the use of electricity for any purpose other than lighting is a novelty. The large range makers and gas-stove people competed very closely for the medals awarded by those interested. Messrs. Crompton have been more successful than the majority by carrying off two prize medals and highest awards. One was given for the improved electrical cooking apparatus, and the other for improvements in domestic motors, with a new reducing gear applied direct to the motor, thus saving the necessity of bands and pulleys. Messrs. Crompton show a dynamo which drives arc and incandescent lamps for lighting the building, and supplies the current for the cooking apparatus, ventilating fans, etc. The working of the electric kettles, cookers, and hot-plates was watched with great interest by all attending the congress, and it was acknowledged to be a move in the right direction. Mrs. Knight, the cook employed by the institute to demonstrate the use of the gas and other stoves on trial, prepared food by the electric cookers every day, and proved that the electrical apparatus was not only equal, but superior in many respects to the gas cooking appliances formerly employed. Mr. H. J. Dowsing has been down on several occasions and given short lectures explaining the uses of the various apparatus, and altogether the innovation of competing with the makers of coal ranges and gas stoves has created great interest. We understand that it is the intention to introduce electricity as a sole cooking power in several large flats in the West end of London nearing completion, where it was formerly intended to instal gas stoves. The supply companies will make a special reduction for current used for driving domestic machinery and cooking apparatus, and this will encourage its use, and increase the day demand for electricity. Messrs. Crompton are introducing a number of new applications in the way of electric heating, and their showrooms as 148, Brompton-road will shortly be completed. In the window may now be seen kettles boiling by electricity and warming apparatus at work, and the large numbers of passers-by that stop to look in prove the interest evinced in the matter. The Health Exhibition at Portsmouth will remain open for a further three weeks, and during the first week it has been well attended. If visitors are not interested in electric cooking, they will find æsthetic culture in listening to the strains of the band—a band of ladies.

THE EFFICIENCY OF TRANSFORMERS AT DIFFERENT FREQUENCIES.*

BY W. E. AYRTON AND W. E. SUMPNER.

Some years ago Mr. Mordey published in the *Journal* of the Institution of Electrical Engineers the results of some experiments, which appeared to show that when a transformer of the Mordey type of construction was working at a given load, the waste of power was less at a frequency of 100 than at a higher or lower frequency. In 1888, to test this point, experiments were carried out at the Central Institution by Messrs. Lamb, Smith, and Woods, the power put into and taken out of a Mordey type of transformer being measured by the electrometer method, and it was for the purpose of these tests that there was constructed the large non-inductive resistance that was described by Mr. Mather and one of us before the Physical Society last year. But although this method is theoretically one of the best for ascertaining the power given by any current to any circuit, the percentage error in measuring the efficiency is, of course, the percentage error in measuring the power put into or taken out of the transformer. And, as it is very difficult to avoid making errors of 1 or 2 per cent. with the electrometer method, it is almost impossible to be sure of changes of this magnitude in the efficiency produced by a variation in the frequency. Subsequently, tests were made by others of the students, employing other methods for measuring the power, but it was not until one

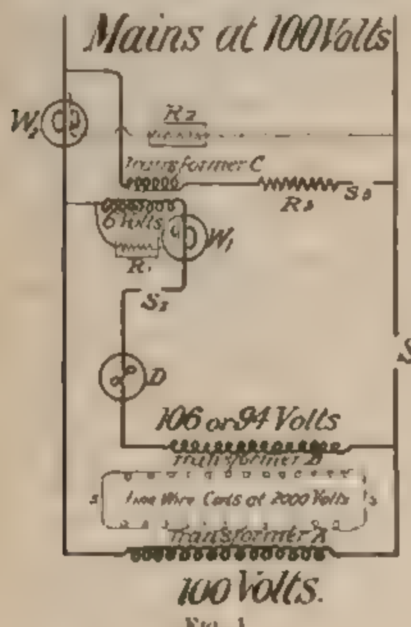

FIG. 1.

of us had devised the method that appeared this year in the technical press for measuring the losses in a transformer *directly* that we felt in a position to express an opinion regarding the actual effect produced by variation of frequency on the efficiency of a transformer. Except under special circumstances, to be subsequently referred to, this method requires for its employment two transformers similar in type and output, and a third transformer, which may be of much smaller output, for supplying the energy lost in the coils of the two large transformers.

The detailed working of the method will be understood on reference to Fig. 1. The fine wire coils of the two transformers, A B, are connected in parallel through the high pressure switches, *s s*. The thick coil of A is connected directly with the mains, while the thick coil of B has one of its ends joined with one of the mains, and the other in series with a dynamometer, D, a switch, S_2, the current coil of the wattmeter, W_1, the secondary of the subsidiary transformer, C, and finally with the other main lead. A switch, S_1, is placed in one of the mains, as indicated in the figure, so that the current supplied directly from the mains can be switched off when desired. The primary of transformer C is connected with the mains through an adjustable resistance, R_3, and a switch, S_3. A wattmeter, W_2, has its current coil joined up so as to be traversed by the current entering the parallel circuit formed by the primaries of A and B, and its pressure coil placed in series with the non-inductive resistance, R_2, across the mains. The pressure coil of the other wattmeter, W_1, is connected in series with the non-inductive resistance, R_1, across the secondary of the auxiliary transformer, C.

If the switches S_1, S_2 be closed, the currents flowing are merely the magnetising currents required for the transformers A and B, and W_2 merely measures the open-circuit losses. Unless the secondary of C be short-circuited no current will flow through the thick coil of B, for the magnetising current is then supplied by the thin coil after transformation by A. If now switch S_3 be closed, so that the secondary of C supplies a P.D of, say, six volts to the circuit formed by the thick coils of A and B, large currents will flow through the transformers. The P.D. between the terminals of A will be of course the voltage of the mains (for example 100), but the P.D at the terminals of B will be either 106 volts or 94 volts, according as the six volts supplied by the secondary of C are in opposite phase, or in the same phase, as the 100 volts between the mains. Indeed, if there were considerable magnetic leakage in the transformer C, or if R_3 were a highly inductive resistance, the P.D. of six volts supplied by C would be out of phase with the voltage on the mains, and the P.D. at the terminals of B might be anything between 106 and 94 volts. If there be a P D. of 106 volts between the terminals of B, this transformer is being used as a step-up transformer, and A is converting downwards. If, however, there be only 96 volts between the terminals of B, it is A which is working as the step-up transformer, and B which is converting downwards. In the majority of the cases to be subsequently described the six volts supplied by C were sufficient to drive the full load currents through the transformers.

The load, W, we take as being measured by the product of the current indicated by D and the P.D. supplied to the primary of the step-up transformer. If A is used for converting upwards, this load is simply 100 times the current in amperes, whereas if B is used as the step-up transformer the power returned to the mains by A is 100 times the current in amperes, and if to this we add the two power losses measured by W_1 and W_2 we obtain the power taken from the mains and supplied to the primary of B. If w be the load in watts supplied to the step-up transformer, if w_1 and w_2 be the watts at this load measured by W_1 and W_2 respectively, and if λ be at the same time the loss of power in the leads used in joining up transformers, in the coils of the dynamometer, D, and in the current coil of W_1, the total loss in the two transformers is $w = w_1 + w_2 - \lambda$, and the efficiency of the double conversion is $\eta = 1 - \frac{w}{W}$.

The advantage of this method of determining efficiency, as pointed out some years ago by Dr. Hopkinson in connection with a similar method of measuring the efficiency of dynamos and motors, is that a small error in determining either w or W will make practically no difference in the calculated value of η. For instance, as the value of η for two transformers is about 90 per cent., w is about one-tenth part of W, and it follows that an error of 10 per cent. in estimating the ratio of w/W only affects η to 1 per cent., and only affects the calculated efficiency of each transformer to one half per cent. It would have been more accurate had we placed the dynamometer, D, in circuit with the thick coil of A rather than with the thick coil of B, but the currents in the coils of A and B for closed magnetic circuit transformers differ to such a slight extent that either current may be approximately taken to represent the load without introducing any appreciable error in the determination of the efficiency.

The instruments used were of a rough character, and no special care was taken with them, for our object was rather to see how far measurements made by this method with common instruments could be relied upon, than to obtain the most accurate results possible. D (see Fig. 1) is an ordinary Siemens dynamometer measuring up to 55 amperes for one revolution of the pointer when the thick coil is in circuit. W_2 is a Ganz wattmeter, supplied, as usual, with two non inductive resistances. In the following

* Paper read before the meeting of the British Association at Edinburgh.

experiments its sensibility was such that one revolution of the pointer corresponded with about 1,200 watts. W_1 is a Siemens dynamometer as made commercially, but modified so as to form a wattmeter by connecting the mercury-cups forming the ends of the movable coil with two separate terminals. This swinging coil was used in series with a suitable non inductive resistance, R_1, as the pressure coil of the wattmeter, one of the fixed coils being traversed by the main current. When large currents were flowing through the thick coils of A and B, a current of eight or ten amperes often passed through the volt coil of this wattmeter and its attached resistance, R_1, but although the power so wasted was quite appreciable, consideration of Fig. 1 will show that the reading of the wattmeter W_1 is not affected by it in the least, and that it thus does not enter into the calculation of the efficiency. An ordinary Cardew voltmeter was used for the adjustment of the potential on the mains.

The transformers tested were M_1, M_2, two transformers of the Mordey type, each of output 4·5 kilowatts, converting from 2,000 volts to 100 volts (or 50 volts). They are numbered 1,871 and 1,872. We shall for brevity allude to them respectively as M_1 and M_2. M_3, one transformer of the Mordey type, of output three kilowatts, converting from 2,000 volts to 100 volts (or 50 volts) Its number is 1,832, and in what follows it is alluded to as M_3. M_4, one transformer of the Mordey type, of output 1·5 kilowatts, converting from 100 volts to 100 volts. It has three coils, each of the same number of turns, and occupying spaces proportional to the numbers 1, 1, and 2 respectively. The transformer was wound in this way for experimental purposes, but in other respects it does not differ in construction from the ordinary type made by the Brush Company in 1887. It is alluded to in the following experiments as M_4. H, one Hedgehog transformer, made by Messrs. Swinburne and Co., of output four kilowatts, converting from 2,000 volts to 100 volts. It is referred to by the letter H. A small transformer of change ratio 6 to 1 was occasionally used as the subsidiary transformer, C. It was not, however, of any recognised commercial type, and the magnitude of its efficiency does not enter into the tests.

The losses in the leads were carefully determined, and confirmed by measurement made with different methods. The same leads and instruments were used in all the experiments. The first method of testing was to measure the resistances of the different coils and leads and calculate the losses at the currents used. These measurements were confirmed by passing steady currrents of 30 and 40 amperes (measured by a standard d'Arsonval galvanometer used as an ammeter in shunt to a platinoid strip) through the leads, and measuring with the aid of a standard voltmeter (a second d'Arsonval galvanometer used in series with known resistances) the power lost in the leads for these currents. The same experiment served to calibrate the dynamometer, D. The wattmeters W_1 and W_2 had been previously calibrated by means of the same two standard instruments. The measurements were made when both the thin and the thick coils of the dynamometer, D, and the wattmeter W_1 were in circuit, since in the actual transformer tests it was occasionally found necessary to change these coils The measurements of the losses in the instruments and leads were further confirmed by tests with alternate currents of the same frequencies as those used in the measurements; and it will be apparent that one of the advantages of the method of testing the efficiency of transformers which we have employed arises from the fact that the apparatus required for the efficiency measurements can be used for determining the losses in the leads, etc., without any alteration of the connections. For if the switch S_1 be open, and switches S_2 and S_3 be closed, and the primaries of the transformers A and B are short-circuited, the reading of the wattmeter W_1 will at once measure the losses occurring in the testing apparatus itself when any special current, measured by D, is passing through it. The measurements made by these different methods were in quite satisfactory accordance with each other. With a current of 40 amperes the loss in the leads, when the thick coils of D and W_1 were used, was 55 watts. When the thin coil of D was substituted for the thick coil, the extra loss at 40 amperes was 70 watts, and an equal increase in the loss was caused by using the thin coil of W_1 instead of the thick coil.

The losses occurring in the coils of the transformers can be measured independently of the other losses by simply leaving the switch S_1 open and taking the reading of W_1 for different alternating currents flowing through D. The two transformers A and B are so connected that a P.D. of a few volts will cause large currents to flow through the thick coils when the switches, *s s*, in the secondary circuit are closed. Of course the iron cores are magnetised slightly, and a certain amount of energy is absorbed by hysteresis, but this is quite negligible compared with that lost in the copper. For at most the voltage corresponding with the induction of the core is only that needed for driving the currents through the resistance of the transformer coils. This is only about 1 per cent. of the ordinary voltage of the transformers, and as the losses in the iron vary as the square of the induction density (more accurately as $B^{1·6}$) the core losses are only $0·01 \times 0·01$—*i.e.*, 0·0001 of the normal losses occurring in the use of the transformer. It thus becomes possible to investigate the very important matter of the variation of the core losses under different conditions of load. All that need be done is to determine: (1) The total losses occurring in core, coils, and testing apparatus for different currents when S_1 is closed; and (2) the total losses in the coils and testing apparatus for the same currents when S_1 is open. The difference between the losses found for any particular current is the loss in the core for that particular load.

It was pointed out in the article in the technical press already referred to that the reading of W_2 practically gave the iron losses in the two transformers, and that W_1 gave the losses caused by the heating effect of the currents in the coils, etc. The measurements made with closed-circuit transformers have entirely confirmed this view. Thus for the two 4½-kilowatt transformers of the Mordey type (M_1 and M_2) tested at 100 volts and a frequency of 160, the reading of W_2 gradually changed from 220 watts on open circuit to 230 watts at a load of 2,500 watts, and to 235 watts at a load of 5,000 watts. Whereas the core losses as determined by the subtraction method were 220 watts on open circuit, 220 watts at a load of 2,500 watts, and 227 watts at a load of 5,000 watts, or practically the same as the watts as measured by W_2. In another test, at a frequency of 150, the reading of W_2 changed from 210 watts on open circuit to 222 watts at a load of 4,000 watts, the iron losses as calculated by the difference method diminishing gradually from 210 watts on open circuit to 200 watts at a load of 4,000 watts. In another test at the same frequency, the reading of W_2 altered from 215 watts on open circuit to 210 watts at full load, while the iron losses were found exactly the same as the corresponding readings of W_2 up to a load of 3,000 watts; afterwards, however, the iron losses were slightly greater. In a test at a frequency of about 100 the reading of W_2 decreased from 260 watts to 250 watts as the load increased up to 4,000 watts, the iron losses being the same up to a load of 2,500 watts, and being slightly less afterwards and equal to 230 watts at a load of 4,000 watts. In a later test at a frequency of 100 the reading of W_2 only changed from 285 watts to 290 watts from open circuit to a full load of 5,000 watts, while the iron losses diminished under the same circumstances from 285 watts to 275 watts.

In all these experiments numerous tests at intermediate loads were taken, and the general smoothness of the curves obtained by plotting the observations is such as to justify considerable confidence in the character of the results, the slight differences between the curves denoting the readings of W_2 and those representing the iron losses are sometimes in one direction and sometimes in the other, and are to be regarded as an indication of the extent of the experimental error to which the measurements are subject rather than as any certain evidence of alteration of the core losses with the load. In fact, the experiments seem to show that with closed-circuit transformers at any rate the core losses are practically constant at all loads. This conclusion is only what theory indicates, but it has frequently been doubted, as many published efficiency tests of transformers have indicated that the core losses diminish as

the load increases. This constancy of the iron losses is further evidenced by tests made with the other two Mordey transformers. Thus, in testing the combination of the 4,000-watt Mordey, M_1, with the 3,000-watt Mordey, M_3, the iron loss at a frequency of 160 only altered from 185 watts at no load to 175 watts at a 4,200-watt load. In another test, at a frequency of 200 the core losses changed from 170 watts at no load to 155 watts at a load of 4,200 watts. In a test of the 1,500-watt Mordey, M_4, the iron losses at a frequency of 160 were found constant within 1 per cent., while the load changed from 0 to 3,000 watts, or double full load.

When the open magnetic circuit transformer was used, the measurements were not so satisfactory. Two or three reasons may be assigned for this. Owing to the large mag-

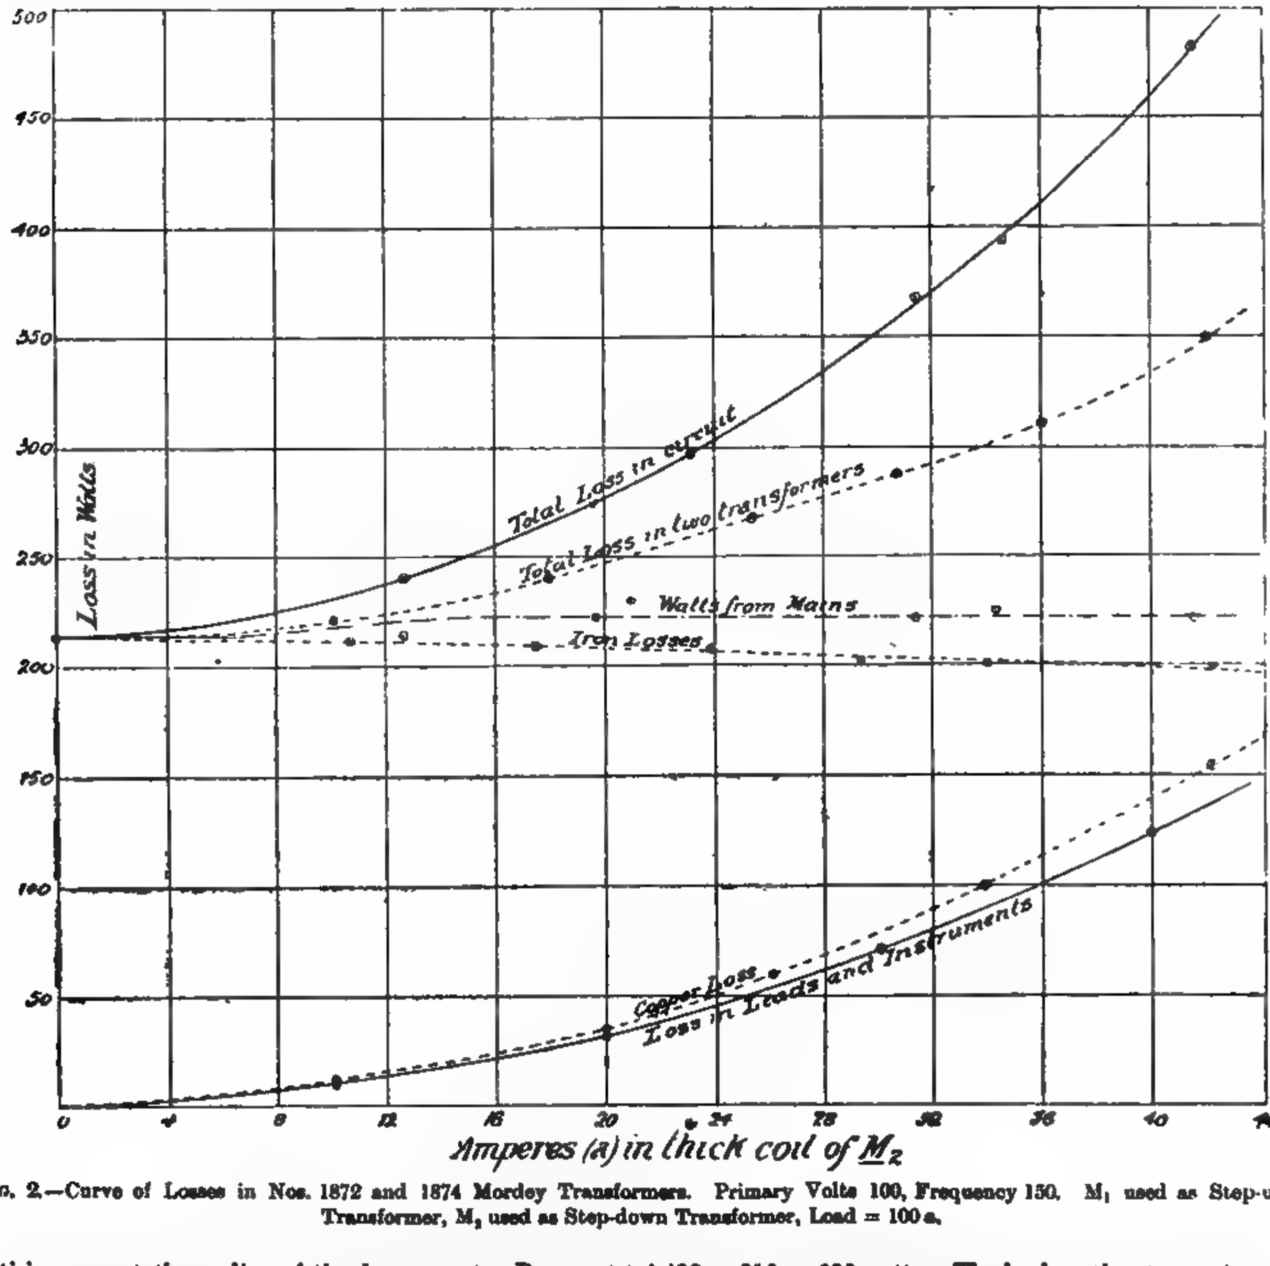

FIG. 2.—Curve of Losses in Nos. 1872 and 1874 Mordey Transformers. Primary Volts 100, Frequency 150. M_1 used as Step-up Transformer, M_2 used as Step-down Transformer, Load = 100 a.

netising current, the reading of the dynamometer, D, cannot be taken to indicate the current in the thick coil of A as well as that in the thick coil of B. Also, owing to the great difference in the regulation of the Hedgehog transformer when converting up or down, the voltage on the transformer C had to be considerably greater than in the previous tests when the full-load currents were flowing; and, consequently, while one of the transformers A, B is worked at the proper voltage, the other is worked at a voltage considerably different from 100. The curves obtained are sometimes of a curious character, and we have not yet had time to fully explain them. As we hope to repeat these tests, we prefer to postpone the publication of the results referring to the core losses of open-circuit transformers. Our experiments, however, indicate that the iron losses do not alter by as much as 10 per cent. when the load is increased from 0 to full load.

Before summarising the results obtained it will be well to explain in detail the arithmetical working by means of which the efficiency is obtained from a single set of measurements with the three instruments W_1, W_2, and D. When the two large Mordey transformers, M_1 and M_2, were being tested at a frequency of 107, it was observed that when the current as read by D was 44·8 amperes, W_1 indicated 310 watts, and W_2 indicated 290 watts. In this particular experiment M_1 was on the mains at 100 volts, and was used as a step-down transformer, the volts on the primary of M_2 being greater than 100 volts. While, therefore, $44·8 \times 100$ watts were being returned to the mains by M_1, the thick coil of transformer M_2 was being supplied with $4,480 + 310 + 290$ watts. The load on the step-up transformers was thus 5,080 watts. The total loss in the two transformers is, however, less than 600 watts, since there is a considerable loss in the leads and dynamometers, etc. The loss in the leads at 44·8 amperes is 63 watts. The thin coil of W_1 was used in this particular test, so that an additional loss of 89 watts must be allowed for. No extra allowance has to be made for D, as the thick coil was used, and the loss in this coil is already taken into account in estimating the loss in the leads. The total loss in the testing apparatus for this current is, therefore, 152 watts, and the total loss in the transformers is thus $600 - 152 = 448$ watts. The joint efficiency at this load of 5,080 watts is, therefore, $1 - \frac{448}{5,080} = 1 - ·0883$

= 91·18 per cent. This number is the product of the efficiencies of the two transformers, and, if these are assumed to be equal, the true efficiency is obtained by taking the square root of 0·9118 giving 95·5 per cent. Also if the copper losses at this current, determined by the method already described, be subtracted from the total loss of 448 watts, we obtain 275 watts as the iron losses at this load. This only differs by 15 watts from the actual reading of W_2.

This process has been gone through for each of the efficiency determinations made; but in order to simplify the work, curves have been plotted denoting respectively the losses in the leads, in the transformer coils, the total losses in leads and transformers, the total losses in the transformers, the losses in the core, and the corresponding power supplied by the mains and measured by W_2.

The curves shown in Fig. 2 indicate a complete set of observations made on the two large Mordey transformers, M_1 and M_2. As many as 30 such sets were taken in connection with different combinations of the transformers. Several of these had to be rejected from various causes. For instance, it was at first arranged, by means of a combination of switches, to make one wattmeter do the work of the instruments W_1 and W_2, but after several measurements had been taken it was found that the alteration of the resistance of the circuit caused by the introduction of the wattmeter coil altered the currents flowing to a serious extent. The majority of the tests, however, confirmed each other in a very satisfactory manner. It is unnecessary to give the details of all the measurements, and we shall, therefore, merely give the numbers denoting the losses at different loads. These losses are interpolated from the curves drawn through the actually plotted points. The following table shows the results obtained from five sets of observations at various frequencies on the two large transformers, M_1 and M_2:

Combined Losses in Two 4½-Kilowatt Transformers of the Mordey Type.

Load in watts.	Approximate frequency in periods per second. Loss in watts in the two transformers.		
	100	120	160
1,000	292	270	229
2,000	305	280	241
3,000	335	[illegible]	275
4,000	375	345	320
4,500	400	—	—
5,000	425	—	—

From these numbers we obtain the following values for the efficiency of each of these two transformers:

Load in watts.	Approximate frequency in periods per second. Efficiency of each transformer.		
	100	120	160
1,000	84·46	85·59	[illegible]
[illegible]	92·19	92·76	[illegible]
3,000	94·27	94·79	[illegible]
4,000	95·22	[illegible]	[illegible]
4,500	95·46	—	—
5,000	95·76	—	—

From these numbers it follows: 1. That the greater the frequency the higher the efficiency for any particular load. 2. That the greater the load the higher the efficiency for the same frequency. Both these results follow, of course, from the fact that the iron losses are the same at all loads for a given frequency, and diminish as the frequency increases. And they do not, for these particular transformers at any rate, confirm the results referred to at the commencement of this paper that the efficiency is a maximum at the frequency of 100.

The open-circuit losses expressed as percentages of full load are 3·2 per cent., 2·8 per cent., and 2·36 per cent. at frequencies of 100, 120, and 160 periods per second. If the iron losses be constant for all loads at a given frequency it can easily be proved that the efficiency of a transformer must be a maximum when the copper losses become equal to the iron losses. And calculation shows that, for these two 4½-kilowatt transformers of the Mordey type, this equality will occur at a load of 7,200 watts at a frequency of 100, at a load of 5,500 watts at a frequency of 160, and at a load of 5,000 watts at a frequency of 200 periods per second when the maximum efficiencies become 96 per cent., 96·1 per cent., and 96·3 per cent. respectively. There is, therefore, no great difference between the maximum efficiencies at different frequencies, but the higher the frequency the lower the load at which the maximum of efficiency occurs.

The following table summarises the results obtained from the tests of the 3,000-watt, M_3, and the 4,500-watt, M_1, transformers of the Mordey type combined.

Load in watts.	Frequency in periods per second. Loss in watts in the two transformers.		
	107	160	200
0	235	185	175
3,000	320	265	255
4,000	410	340	[illegible]

From these numbers we obtain the following values for the joint efficiencies of these two transformers:

Load in watts.	Frequency in periods per second. Joint efficiency of the two transformers.		
	107	160	200
3,000	[illegible]	91·17	91·60
4,000	89·75	91·50	90·88

Now from the former tests we know the efficiency of M_1 at these loads and at two of the frequencies. We can thus obtain, by division, the efficiency of M_3, as follows:

Load in watts.	Frequency in periods per second. Efficiency of transformer M_3.	
	107	160
3,000	94·76	95·66
4,000	94·25	[illegible]

The efficiency of the small 1,500-watt transformer, M_4, of the Mordey type was tested at a frequency of 150 and found to be 90·2 per cent., at a load of 1,500 watts, and higher at a larger output. The method used in testing this transformer is of some interest, arising from the fact that, as already stated, this transformer was for special experimental reasons so wound that it transformed from 100 volts to 100 volts. Now, when the change ratio of a transformer is unity, it is not necessary to employ another similar transformer when using our method of testing the losses directly, since the primary and secondary coils can be employed, one to take energy from the mains and the other to give back what is not lost in the transformation. Of course, an auxiliary transformer (C, Fig. 1) must be employed, but the two transformers, A and B, in the figure are replaced with the single-unity-change-ratio-transformer, M_4.

As the large transformers of the Mordey type are wound with two thick wire coils in addition to the fine wire one, in order that the transformers may, if required, be used on the three-wire system, it is possible to measure the efficiency by the method last described with the employment of a second similar transformer. And tests that we made in this way confirmed those previously carried out.

But, as the fine wire coil of the transformer is not used, this method, although excellent for a transformer whose change ratio is unity, is not to be recommended for one which transforms from 50 or 100 to 2,000 volts. Indeed, it is obvious that if the test be made in the way just described, the advantage of dispensing with the duplicate transformer is counterbalanced by the fact that the transformer tested can only be used at what is practically half load, and the copper losses are therefore proportionately greater than when the transformer is used in the ordinary way at full load. Employing, therefore, two similar transformers as well as a small auxiliary transformer, as in Fig. 1, is much to be preferred.

A large number of tests were made by combining the Hedgehog transformer, H, with M_1 and with M_3, and, although the results (as already mentioned) were not as

satisfactory as when two Mordey type of transformers were employed, they were sufficiently accurate to show that neither at no load nor at full load is there any great difference, apparently, between the power wasted in a Hedgehog and in a Mordey type of transformer of the same output. On this point, however, we shall say more when we have had more time to analyse the results we have already obtained with the Hedgehog transformer.

In conclusion, we wish to express our thanks to the Brush Company for so kindly lending us the two 4½-kilowatt transformers, and also our obligations to several students at the Central Institution, and more especially to Messrs. Baillie, Baylay, and Clift for their interest and energy in carrying out the experiments, and in reducing the results.

Lamp Trimming.—Safety bicycles are now being introduced in America for the lamp trimmers to make their rounds more quickly.

STEAM AND GAS ENGINES AT THE CRYSTAL PALACE.

Among the engines which were present in the largest numbers were the Crossley Otto engines, of the more usual and of the special high-speed types, and the Stockport engines of various sizes and forms. Of the former, we give herewith a perspective view, Fig. 1, as this engine is specially designed to run at the high speed from which the desirably uniform speed required for driving dynamos is more certainly obtained than with the lower speed. Another advantage obtained by the use of the high speed engine is a smaller difference between the size of the flywheel and the pulley on the dynamo, thus securing better running of the belt with smaller tension upon it. In this engine every refinement which Messrs. Crossley Bros. have brought out is employed, including the timing valve for ensuring regularity of ignitions in the heated tube, and the governor made so that within certain limits the engine may be made to run

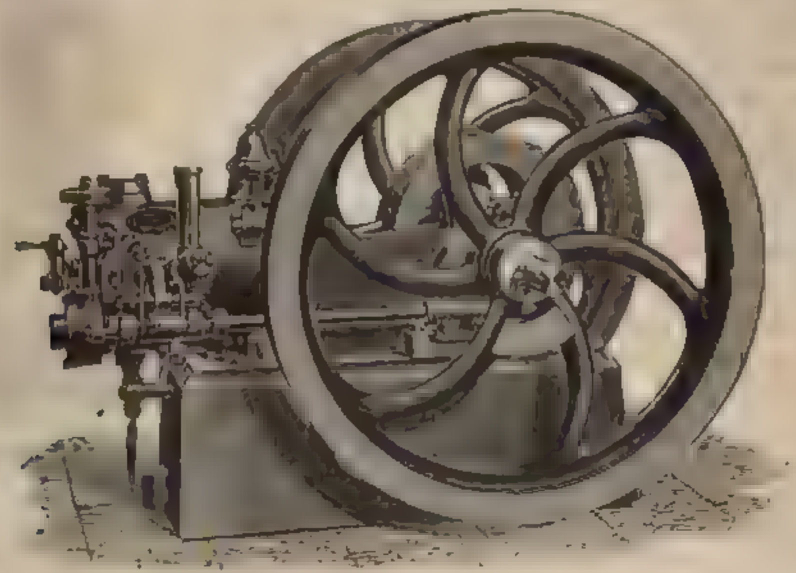

Fig. 1.

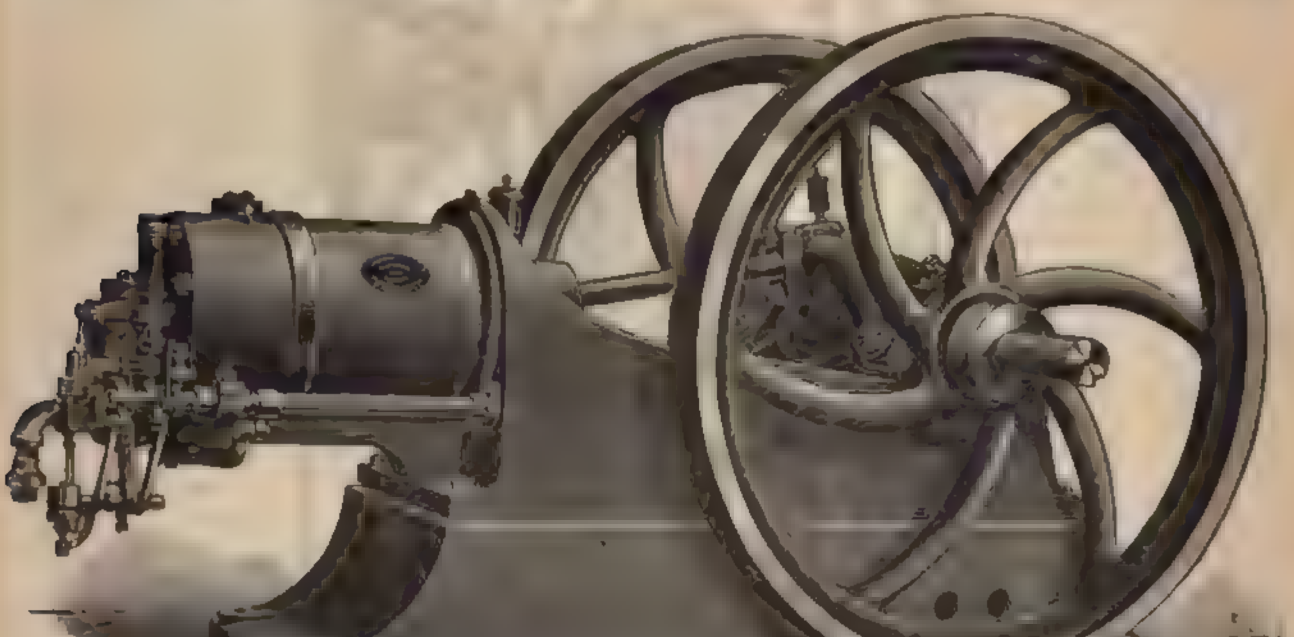

Fig. 2.

at any desired speed. The engine being constructed on the Otto principle is, of course, single-acting, and great care has been taken in balancing the reciprocating parts, the balancing weights being so placed that they move at the same mean velocity as the parts to be balanced. Messrs. Crossley Bros. are fitting their larger engines with self-starters, and they exhibited several other forms of their engines, including the vertical, and all were of the highest class of design, workmanship, and finish.

The Stockport engines exhibited by Messrs. J. E. H. Andrews and Co. were of several forms and two kinds—namely, the double-cylinder or displacer cylinder Stockport engine, and the newer Stockport Otto engine, the latter being made both in the horizontal and vertical forms, as shown in Figs. 2 and 3. Fig. 2 shows the engine as fitted with the makers' timing ignition valve, and with their self-starting apparatus. By means of the timing valve the ignition is prevented from taking place until the crank is past the centre in the position for working in the proper direction. It may be mentioned that the Morecambe Electric Light Company is using three of the large engines as shown in Fig. 2 for its central station, the engines being of 16 nominal horse-power, and have to give current to about 1,000 16-candle lamps. The self-starter used on these engines is of a very simple character. A small gas inlet cock is placed in connection with the port which usually allows the exhaust gases to escape. The exhaust valve is for the time prevented

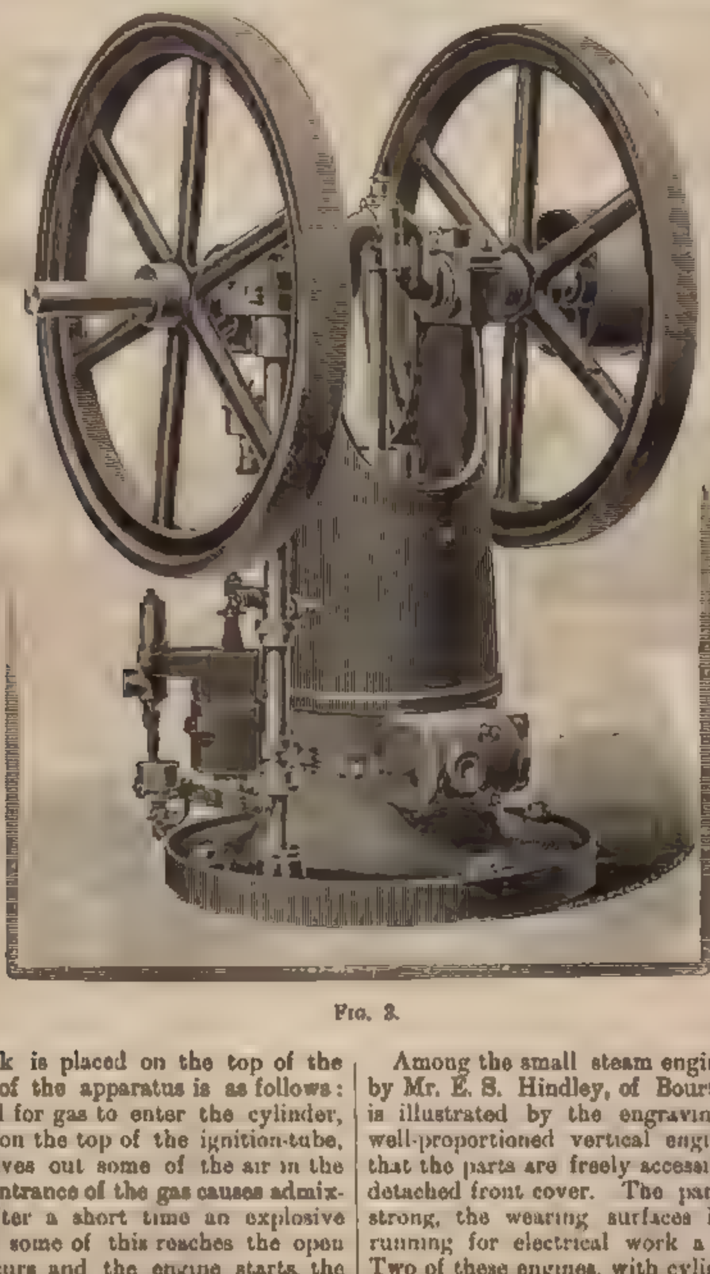

Fig. 3.

from acting. Another cock is placed on the top of the ignition-tube. The action of the apparatus is as follows: The gas-cock being opened for gas to enter the cylinder, and the cock being opened on the top of the ignition-tube, the entrance of the gas drives out some of the air in the cylinder. The continued entrance of the gas causes admixture of gas and air, and after a short time an explosive mixture is formed. When some of this reaches the open ignition-tube explosion occurs and the engine starts, the special gas admission cock and the emission cock on the ignition-tube being simultaneously closed by the pressure which follows the explosion. Self-starting gear is of great importance in connection with the use of the larger gas engines, and they add very considerably to the size of the engines, which can be conveniently handled.

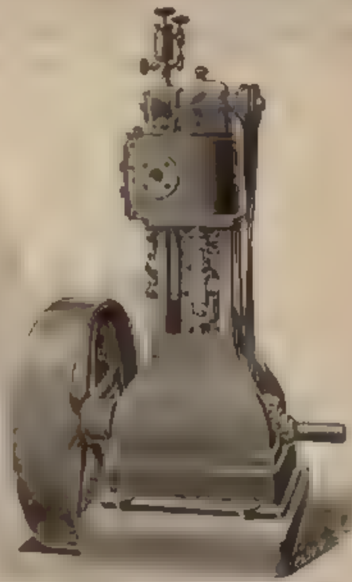

Fig. 4.

Among the small steam engines exhibited were several by Mr. E. S. Hindley, of Bourton, Dorset. One of these is illustrated by the engraving (Fig. 4). It is a neat, well-proportioned vertical engine, with a frame so made that the parts are freely accessible by removing an easily detached front cover. The parts of the engine are very strong, the wearing surfaces large, and for high speed running for electrical work a special governor is fitted. Two of these engines, with cylinders 7in. diameter and 7in. stroke, were employed in driving several machines at the Palace, and they worked very satisfactorily.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

* Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 10d.	9s. 11d.	19s. 10d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

ELECTRICITY AND THE MEDICAL PROFESSION.

This is the title of an article of which the editor of our esteemed contemporary the *Electrical Review* forwards us an advance proof. It is not our custom to criticise the words or views of our contemporaries, but in this case we feel that the full influence of all technical electrical papers should be given, if only to assure the general public we are of one mind as to the true value of apparatus which can only go to form the stock-in-trade of quacks and charlatans. Our contemporary has long carried on a crusade against the curative properties of a "Harness belt." We have all along felt that such a crusade partakes of the nature of a hopeless struggle. The readers of technical papers do not buy magnetic belts, magnetic boots, or magnetic hair brushes. They have, as a rule, enough moving in a magnetic field without resort to these extraneous aids even if they believed in them, which they do not. While papers of a general character are so easily bought and sold by advertisments, and while testimonials frankly given are so easily obtained, and while doctors themselves testify generally rather than specifically, so long will quackery and charlatanism prosper. Our contemporary's article is based upon a pamphlet entitled "The Treatment of Disease by the Prolonged Application of Currents of Electricity of Low Power, being an extract from the latest edition of 'Massage, Electricity, and Allied Methods of Treatment,'" by Herbert Tibbits, M.D. We also received a copy of this pamphlet and an invitation to visit the "Electropathic and Zander Institute," but had no intention of noticing the one or visiting the other. That some very divergent opinions obtain as regards electricity and the human body we well know, but we are surprised to learn that any divergent opinion obtains about Harness's electropathic belt. Let us at once acknowledge, which we believe is a fact, that at the Zander Institute will be found some excellent specimens of electrical and other apparatus, much of which may be beneficial if used properly by weak humanity. As we take it, our contemporary is not protesting against anything but the trading upon an ignorant but superstitious and believing public in order to sell apparatus which has little to recommend it except "faith." Dr. Tibbits, for example, testifies to having tested Mr. Harness's electrical appliances, and contends to have proved that "these experiments prove conclusively that a current of electricity penetrated the skin and influenced the subjacent tissue." The galvanometric deflections were obtained by pricking the skin; but, as our comtemporary points out, the ordinary belts "are not furnished with platinum needle points one-third of an inch long for the purpose of puncturing the skin." An infinitesimal current obtained by such puncturing does not mean even an infinitesimal current without such puncturing. How, in the name of common sense, is the body, or any part of the body, brought into the circuit when using the ordinary magnetic belt? We have heard a good deal about the curative properties of electricity, but with this we have nothing to do. We want to know something of the curative properties of a weak—very weak, if any—magnetic field. Let us drop the

idea of "current," because there is no current, while if the belt itself gives a feeble current there will be around it a current-field or a magnetic field due to the current in the conductor. It is this field we usually have to talk about, and what does Dr. Tibbits or Mr. Harness know about it, or its properties? They tell us nothing about it, hence we take it for granted that they do not understand much about the apparatus they use and talk about so glibly.

THREE YEARS' HIRE SYSTEM.

It is tolerably certain that almost all electrical firms and companies are troubled with symptoms of impecuniosity, and to ask them to embark in a venture that requires a large capital is a bold undertaking. Nevertheless we have to commend to their notice an old, a well-tried, and a successful system known as the hire-purchase system. No doubt in many minds this system is almost entirely associated with the getting of pianos, but business men know that it largely permeates through all businesses. The engine builder is not above taking a leaf out of other folks' experience, and many of the highest firms are paid by instalments, and glad to do business in that manner. If the engine builders can do this, the dynamo builders will have to follow suit, and especially those who are going to pay particular attention to motor work. In the first place, we must assume that good motors can be obtained whether for direct or for alternate current. The amazement is that one or other of the existing big firms have not long since caught on the idea and pushed it as vigorously as we know they can push business which promises good returns. Harking back once more to central station work and constant load, the aim of the management is to sell all the current possible—in fact, we all aim at making money. With the spread of mains there must be hundreds of adjacent premises wherein motors could be put to good use, either for new purposes or replacing old steam engines or gas engines. Numbers of men in a small way of business cannot see their way to get rid of an old engine. It does its work, and they cannot spare the money to replace it by a motor, though they would make an effort to pay for the motor by instalments. We are perfectly certain that though electricity is in one way much dearer than coal or gas, in a large percentage of cases the ultimate bill to the user would be lower than when using either steam or gas. Users have not yet realised the enormous advantages gained in space, in cleanliness, and, above all, in not paying for power except when using it. The switch that turns on the current is also used to turn it off. No electrical energy is paid for when the switch is off, and it is here the gain comes in. With steam or gas, coal and gas and water are always being used. Further, we are under the impression that an electric motor will not deteriorate with age and use so much as a steam or gas engine. However, it is little use to discuss such questions here. From information received—as the police say—it would seem that the adoption of the hire-purchase system would bring grist to the mill. Rumours are rife that the "City" is to be made acquainted with a company having this object in view, but we fancy the industry has been sufficiently cursed with promotion-money, and that existing firms may well develop the business themselves.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC LIGHT AND POWER.

SIR,—I am obliged to Mr. Shippey for the valuable information given by him in his letter to you of the 15th inst. respecting the date of the production of the first arc light. I agree with him that there were other experimentalists in the field whose names ought not to be overlooked as pioneers in electric lighting. I thought it right to date the birth of the electric arc light from the *first public occasion* on which it was seen. I did not record other names for the simple reason that the historical sketch is made very brief and general, and any further reference or extension would be out of place. I afterwards found that I had made a mistake respecting the "Grove" cell, which will be corrected. With Mr. Shippey's kind permission I should be glad, when bringing my articles out in book form (of which those given in the *Electrical Engineer* will only form a part), to insert his remarks respecting the early workers, for the benefit of those who may be interested in historical records of electricity.—Yours, etc.,

Sept. 21, 1892. ARTHUR F. GUY.

SIR,—The science of electricity owes so much to the science of chemistry that it is scarcely fair of electricians to base their arguments—even inadvertently—upon erroneous chemical data. Hence I feel it incumbent upon me to call in question a few of the statements used by Mr. Arthur F. Guy in his paper under the above title. Let us, for example, analyse the very first sentence of the article on "Evolution of Electrical Engineering," appearing in your issue of September 16. It runs thus: "A pure and healthy atmosphere is dependent upon the amount of oxygen present . . ." To use the author's own words in a later clause, "this is a *very great* mistake." The true facts of the case may be stated thus: After the researches of Priestley and Lavoisier it was fully recognised that oxygen was the great supporter of life and combustion, and that the chief function of nitrogen was to keep its action within proper limits. Then it was thought that the great secret of health had been discovered, and that air was wholesome in proportion to the amount of oxygen it contained. But this theory has long been exploded, since it has been shown that the variation in the percentage of oxygen in good and bad air is extremely slight. This subject was thoroughly investigated by Dr. Angus Smith. From a great number of analyses this experimenter found that the *extreme* variations in the percentage of oxygen in atmospheric air were 20·99 per cent. (by volume) in a sample of air from the Scotch moors, and 20·63 per cent. in air collected from the gallery of a London theatre (where gas was the illuminant) near the close of the performance. Thus, although it is true that expired air contains about 4 or 5 per cent. less oxygen and about 4 per cent. more carbonic acid gas than inspired air, yet the percentage of oxygen in air remains almost stationary even under the severest tests. May I be allowed to ask *en passant* what distinction Mr. Guy places between "all substances" and "matter"; and whether the terms "chemical combining" and "mixing" are used as synonymous or alternative? But now we are told that "the volume of the new gas thus given off is often poisonous"—that is to say, a burning candle, or gas jet, or oil lamp continually produces a "poisonous volume." Poor innocent candle: how we should dread thy flickering flame, so wrapt is it in "poisonous volumes" of its own invention! To continue: "All three vitiate the atmosphere and give off poisonous fumes, the carbon which they contain mixing (*sic*) with the oxygen from the air, and so producing the

deadly carbonic acid gas. . . ." Of this *deadly* gas an ordinary man gives off more than 400 litres per diem; that is to say, produces at least 90 gallons every 24 hours. Ninety gallons per day of this "deadly" gas "known to chemists as carbon dioxide"! The wording of the sentence seems to hint that the very chemical name itself signifies death. It is plainly evident that some electrical contrivance ought to take the place of our excessively dangerous organs of respiration. No wonder that our poets allude so pathetically to human sighs. The woe that causes a deep sigh is dwarfed into insignificance beside the calamity with which such a death scattering sound is fraught. I should like to point out that soda-water, champagne, and other effervescing drinks simply reek with this deadly carbon dioxide. No doubt the author avoids all so-called sparkling wines for this reason.

But let us come down to *facts*. Roscoe and Shorlemmer, in their first volume of "A Treatise on Chemistry," sum up the character of our venomous enemy—carbon dioxide—in these words: "At the same time, however, it does not exert a poisonous action on the animal economy, as, indeed, may be gathered from the fact that it is constantly taken into the lungs and emitted from them; . . ." So, then, carbon dioxide is simply a sheep in wolf's clothing, dressed up for the occasion of its formal introduction to the electrical world. Let me remind Mr. Guy that it is the carbon dioxide *from our own lungs* which is so impregnated with "deadly" properties, and not that given out by the innocent little night-light. In reply to the statement that "there can be no light without heat," I would suggest the case known as phosphorescence.

Next we learn that "in the case of an electric incandescent light the small amount of heat evolved from it is due to the *high temperature* of the lamp filament, and on account of the *vacuum* in the lamp there is no conducting medium for the heat." (The italics are our own.) From this we gather that *a high temperature* is very prejudicial to the production of heat, and that radiation in a vacuum is impossible. The temperature of the sun is so great, and the vacuum between the earth and the sun so vast, that no heat can reach us from that source. May I quote Prof. Balfour Stewart: "Radiation of heat takes place in vacuo as well as in air; for it takes place between the sun and the earth, and between the fixed stars and the earth, and we have no reason to think that all space is filled with some kind of air."

The conflicting statements "that the insurance companies look upon its (electric light) introduction with favour," and that the insurance people have had to draw up very drastic rules in order to protect themselves, need no comment. But, Sir, I have already overstepped the narrow limits of a correspondence column, so with a word I will conclude. If we are to convince the public of the undoubtable precedence of the electric light to all other methods of illumination, we must be quite sure of the grounds of our arguments. To electricians the expression "the public" is a phrase which includes all investigators in *other* sciences, so that our *pros.* and *cons* on the subject of lighting must commend themselves to our contemporary scientists. As an old college friend of the author—whose paper I have dared to criticise—I know I can rely upon Mr. Guy's sympathy with my remarks, although perhaps I have rather warmed up to the discussion. But Mr Guy confesses that there is "no light without heat"; so if I have succeeded in throwing light upon the subject—as, indeed, I hope I have—then heat must accompany my remarks.

Screening myself upon the grounds that the author only "reserves all rights," and that I have questioned those parts which do not to my mind fall under that title—Yours, etc., A. E. RICHARDSON.

High School, Dorking, Sept. 19, 1892.

SIR,—I find on reading over my letter sent to you upon the above subject, and which appeared in your last issue, that a slight mistake in names has occurred in copying my manuscript, and probably to those interested in searching up historical electrical work the name of Izarus's, as stated, would be unknown, and probably cause confusion under these circumstances. I will thank you to correct this part of my letter, which should read: "Izarn's 'Manuel du Galvanisme,'" a work which was published in the year 1805, and from which work I discovered the information published by you; and at the same time I shall be glad if you will also add, after "more ancient school," the following words: "*the idea of the storage of electricity.*" By inserting these few words which were omitted by my clerk, the purport of my letter will be better understood and appreciated by those interested in the fundamental work relating to the battery industry and storage of electricity.

Apologising for intruding on your space,—Yours, etc.,

ARTHUR SHIPPEY.

ON THE MANUFACTURE OF INCANDESCENT ELECTRIC LAMPS.

BY FREDERICK GRAHAM ANSELL, F.C.S.

The manufacture of incandescent electric lamps, although apparently very simple, is in reality a matter of some difficulty, and requires a great amount of care besides a sound knowledge of chemistry and general physics. It will be my endeavour to treat the subject as simply, but at the same time as thoroughly, as possible in these pages, so that the process of manufacture shall be perfectly clear. However, I shall say little or nothing of the glass-blowing, except that it is usual to make the bulbs from glass tubing, and that they are generally made to gauge. Glass-blowing, however, is a separate trade, and to be understood properly must be seen and learnt.

The principal difficulties in making an incandescent electric lamp are, first to make the filament, and then to preserve it. Many experiments have been made to discover the best material from which to prepare the filament, which is invariably the purest carbon that can be obtained. Some experimenters have tried platinum, iridium, osmium, and various alloys with high melting points, but the difficulty always has been to regulate the current so as to give a good light, but at the same time so as to prevent the fusion of the wire, the temperature of incandescence always being so very near the melting point. Consequently metal filaments have all been abandoned in favour of carbon, which, so far as we know at present, has no melting point, although it seems to volatilise and to break if subjected to a current of electricity much in excess of that required to make it brilliant. This apparent volatilisation is best observed in lamps which have been in ordinary use a long while, when it may be noticed that a very thin coating of carbon is deposited upon the inside of the glass.

Several methods have been tried for preparing the carbon filament, some deriving it from paper, some from bamboo, and some from cotton, but, in 1883, Mr. Swan took out a patent for preparing his filaments by an ingenious chemical process from gun-cotton or nitro-cellulose. He takes a solution of nitro-cellulose in, say, acetic acid, and forces it through a die into alcohol of 70 per cent. or 80 per cent. strength. The alcohol sets the thread as it issues from the die, and consequently the thread can be made to assume any desired form of cross-section; but in this state it would still be explosive, so, therefore, it must be treated with hydrosulphide of ammonium, or other suitable deoxidising agent, until it loses the power of burning explosively, when it can be washed, dried, shaped, and carbonised.

I will now fully describe one good method of preparing the filament, and will take as a basis of the operation the purest white crochet cotton I can buy at an ordinary linendraper's shop. Firstly, the skein must be thoroughly washed in clean cold water by agitation, and then boiled to remove the size or other dressing put in by the spinner. It is then to be dried and wound loosely on to square frames made of four round glass rods or small tubes, in such a manner that no two turns of the cotton shall touch each other.

Each free length of cotton must be a little longer than the filament it is designed for. The above frame shows cotton enough for 14 finished filaments, and must now be taken by its two glass hooks or handles, C C, and suspended carefully in a solution consisting of two parts sulphuric acid of specific gravity 1·845, and one part of clean cold water. In making this mixture considerable heat will be

developed, therefore it must be made some hours before it is wanted, so that it may cool down to 60deg. F. before it is used. Whilst it is cooling it will probably throw down a white sediment, and if so the supernatant liquid must be carefully drawn off by means of a syphon. Too much attention cannot be paid to this solution, as a very slight deviation from the proper proportions of water and acid, or from the proper temperature, will render it quite useless for its intended purpose. Nothing but glass and the cotton should be allowed to touch this liquid, which is very corrosive. The cotton will not have to remain in the solution very long, but it must be put in and taken out very gently and must be carefully watched whilst there. It will soon become coated with a transparent gelatinous substance — cellulose. This transformation must be stopped just as the last traces of the strands of the cotton begin to disappear by quickly but gently lifting the cotton out of the acid and plunging it gently into a large quantity of clean cold water. The cotton has now swelled considerably and drawn itself more tightly across the frame. The frame must now be suspended by its hooks for some hours in a gentle stream of clean cold water so that it may be thoroughly washed, but no amount of washing will remove the last traces of the acid, therefore the frame and its cotton must be dipped for an hour or so in a very weak solution of ammonia of about 1 per cent. strength. This will neutralise the acid, and a little further washing in the above stream of clean cold water will make the (I must still call it) cotton fit for the next operation—viz., shaping the filament—which presents no difficulty, the prepared cotton being taken from the water and, whilst still wet, made to assume the form it is intended to make the finished filament. This is most easily effected by winding the cotton over glass tubes suitably arranged in a frame, but some people have used carbon blocks.

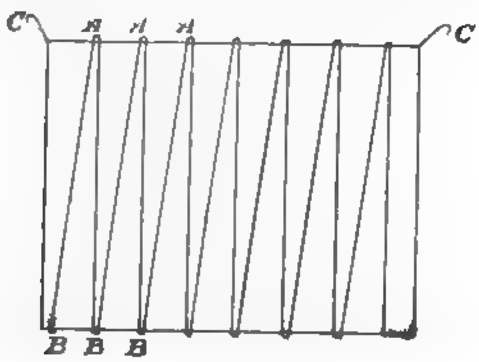

FIG. 1.

The frame or block must in any case be so arranged that each free length of cotton as at A B, Fig. 1, shall be used for one separate filament, and the cotton cut at the place where it passes the tubes from which it is stretched, and which it touched whilst in the acid solution. This precaution is to ensure the filament when finished having the same appearance through its entire length. Any form can be given to the cotton, and when dry it will retain it, but its qualities are now very different from those of the original crochet cotton, it being stiffer and harder, while its breaking strain is much greater. These qualities will afford a fair indication of whether the dipping operations have been properly conducted.

The next process is to coke or carbonise this prepared thread, a process which is easily performed, although it requires considerable care. If we used the former of the two plans for forming or shaping the filament, then these must be cut from the glass tubes and put one by one into an iron box with powdered charcoal sprinkled on the bottom. More charcoal will now be sprinkled on until these filaments are covered, when another layer of filaments can be put in, and so on until the box is nearly full, when at least half an inch of powdered charcoal should be laid on, and then the closely-fitting lid. I believe this plan is generally found better than that of the blocks (although these can, of course, be packed in the box along with the powder), because the carbonisation shrinks the prepared cotton, and, consequently, it is apt to break in irregular places. I have heard, however, of a proposition to put a knife-edge along the carbon block at the place where it is desired to break the prepared cotton. Personally, I like the first plan best, as it seems to me simpler and more certain. The iron box is now to be put into a muffle and gently warmed, in order to expel as much air as possible, and then brought to a good white heat, which must be maintained for some little time—sufficient to allow the whole contents of the box to be brought to the same temperature. This time depends, of course, a good deal upon the size of the box and the heat of the furnace. The box with its contents must now be allowed to cool in the furnace so that no air can enter, or the filaments will be found rotten. The box having become thoroughly cool, the lid may be removed and the contents gently turned out a little at a time on to a very coarse or open sieve, say, with ¼in. meshes, and this being gently shaken, the filaments will remain on the sieve whilst the carbon powder passes through. The filaments should now appear of a good dull black, and be somewhat springy; these two qualities should of course be found throughout the entire length of each filament. If, however, they appear very glossy, it is generally a sign that they have not been sufficiently heated, and in consequence are not properly coked, but if they are irregular in thickness or variously glossy and dull, they may be considered spoiled either from admission of air into the box, the presence of some mineral matter, or insufficient heat. In either case they are no good, and should be thrown away at once.

We have now the carbon basis of our filament, and

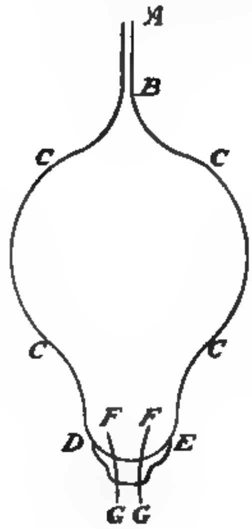

FIG. 2.

FIG. 3.

having laid it on a metal gauge and snapped off the protruding ends to make it the right length, we proceed to mount it on the two little platinum wires passing through the globes, the ends of them having been flattened by a blow from a small hammer, and then bent round so as to form a conical opening into which a little "paste" has been introduced. The filament must be handled very carefully, because in its present state it is very fragile, but it is strong enough to be taken in the finger and thumb and pushed into the "paste." It is then to be put into a warm place to dry slowly but thoroughly. The "paste" is usually made of very finely-ground charcoal and coarse moist sugar with a little distilled water. Sometimes a small proportion of finely-ground plumbago is added. The sugar is added in just sufficient quantity to make the particles of carbon adhere firmly together, and I am constrained to think that the fineness to which the carbon and plumbago are ground in the first instance is a very great factor in the efficiency of the "paste" or "cement." It should be prepared in small quantities at a time and used as fresh as possible. I have tried treacle and turpentine instead of sugar, but did not find them answer the purpose so well. I am told that starch has been used with good results.

I would just mention, by way of explanation, that it is usual, in making the external parts of the lamp, to blow the globe from a fairly large tube, and then having melted glass beads on to the short lengths of platinum leading-in wires to melt these into the bottom of the neck of the globe. A good firm joint must be made here to prevent

air entering after the lamp is finished, so the glass should be well melted on to the wires for quite half an inch, and if necessary can be easily pinched together whilst hot. This being done, and the small tube, A B, having been melted on to the globe, C, the neck, D E, is left ready for the platinum leading in wires, F G, with their glass mounting, as shown.

It is very necessary that all the glass used in any one lamp should come from the same glass house, and if possible from the same pot, as glass of different makes cannot be efficiently joined together.

We will now return to our filament, which is mounted on the platinum wires, as at Fig 3, and found dry. The next operation is known as flashing, and its object is to coat the carbon filament with a thin layer of very hard compact carbon, and so to reduce its initial resistance, which is always very high, to almost any desired amount. There are several ways of doing this, but they are all very similar. In each, the platinum wires leading to the filament should be connected to the terminals of a dynamo machine capable of giving 100 to 150 volts E.M.F., as shown in Fig. 4. Not less than 150 volts should be the figure if it is intended to make the usual 16 c.p. lamps. The filament must now be put vertically into a strong glass vessel, and the air must all be got out.

I will suppose that we are going to flash the filament in ordinary coal gas as it is supplied by the gas companies for lighting. Place a wide-mouthed glass bottle bottom upwards on a suitable stand, procure a well-fitting bung, perforated for two small tubes, and with two wires passing through in the middle, as shown in Fig. 4. Connect the gas-pipe by means of a short piece of indiarubber tube to one of the glass tubes passing through the bung. The other glass tube passing through the bung should be drawn to a small opening at the outer end. The gas may now be turned on, and when sufficient time has been allowed for

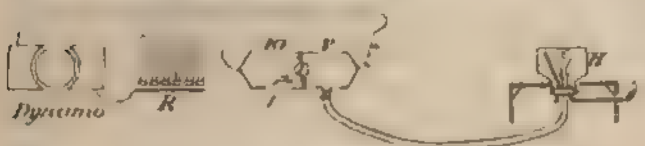

Fig. 4.

the air to be driven out, a flame should be lit at the small orifice. Great care must be exercised to ascertain that all the air is out or an explosion might ensue. It is advisable to have a well fitting bung, and only to put it lightly in the neck of the bottle in case of accidents, but in addition to this it is a good plan to get a penny chemist's test tube, hold it inverted over the nozzle, so as to collect the emanating gas, and then to take it a few yards away (still inverted), and to present it to a flame. If an explosion occurs in it you may know that the large bottle would explode violently, but if the gas only takes fire, and the little blue flame goes gently up to the bottom of the test tube, then there will be no fear of an explosion. The whole arrangement is shown in Fig. 4.

The glass jar being free from air and the filament being arranged as one arm of a Wheatstone's bridge, as shown, and the circuit being easily under control, the current may be turned on and regulated by the resistance coils, R. The galvanometer must now be closely watched, and the very instant the resistance of the filament has fallen to the desired figure the current must be stopped or the filament resistance will be too low—a fault which cannot be remedied. The above sketch shows all the necessary electrical connections, the path of the current being from the dynamo, which should be shunt wound, through the resistance coils, R, which should be about 10 to 25 in number, and of about 10 ohms each, in German silver wire; it then goes to the Wheatstone bridge, one side of which has very high resistances and the other side very low. A good arrangement would be for the top side to have, say, 10 ohms as a fixed resistance and an ordinary box of adjustable resistances, V, varying from 500 to 2,000, while on the other side we might put one ohm for one arm and the filament for the other. The galvanometer should have 1,000 ohms resistance, and should be connected through a spring key. Suppose we wish to make a filament of 150 ohms resistance, then we must arrange the above bridge with its 10 ohms and 1,500 ohms on one side, because 10 : 1,500 :: 1 : 150, i.e., the filament. To flash properly and quickly will require some practice, and a good manipulator need not allow the needle of the galvanometer to swing more than 2deg. or 3deg. In the above arrangement the resistance of 150 ohms for the filament is reached when it is impossible to move the needle of the galvanometer by depressing its key.

When the current is first turned on, probably all the force of the machine will be required to bring the filament to a white heat, but then the deposition of carbon from the gas would be so rapid that it would be impossible to arrest the process at the right time by means of the "bridge" and a simple switch, therefore the resistance coils, R, are inserted into the circuit, so that the temperature of the filament, and, consequently, the rate of deposition of carbon from the gas, may be kept fairly constant by adding resistance to the circuit at any desired speed by simply moving a short contact piece.

On removing the filament from the glass bottle, H, it will be observed to have a grey or steel coloured appearance, but I have never found this very pronounced on filaments flashed in coal gas. However, for sale purposes this appearance is much valued, and consequently some factories have to flash twice, the second time being in an atmosphere of benzene vapour. Personally I am not in favour of this double flashing, as I have flashed continuously in benzene, and have invariably obtained good results at one operation. Therefore I should recommend that gas, with its attendant dangers, be altogether discarded, and benzene adopted in its place, the small extra expense for the difference in the flashing apparatus being more than counterbalanced by the ease in working and by the results.

(To be continued.)

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE II.

(Continued from page 290.)

Now we come to the question of high pressure supply. It was perfectly obvious, from the earliest attempts at distribution, that we should lose very considerably if we tried to extend low pressure to any great distances, and the obvious remedy for the difficulty lay in using high pressure, which involves smaller wires at any rate. The old attempts that were made were of two kinds. The first attempt was by means of storage batteries; and in my previous Cantor lectures I was able to give you an account of a great attempt that had been made to introduce such a system at Colchester. The scheme died from various causes among others, that the batteries which were employed were not thoroughly reliable. An exactly similar scheme has since been worked out in Chelsea by the engineers who superintended the Colchester system; we have there an example of storage batteries, put into sub-stations, which are charged all in series by high-tension mains, and which discharge into the houses by independent low-pressure mains. That system is one which we can see now, as the result of some time of working, is satisfactory in many ways, the only serious objection being probably its cost. That is the only case of that sort which has been before us, and is one which interests us very much, as being a development we would wish to see thoroughly successful. The other attempts directed towards a system of parallel-series made in previous days were all distribution, as we have called it. The lamps and mains were divided into groups, the lamps of each group being put in parallel, and the successive groups put in series. So, it would be possible to have a dynamo working at 400 volts, with five main wires in the distribution network, the lamps being placed between the first and the second, the second and the third, and the third and the fourth. There would be thus four groups of lamps, which would be in series

* Cantor Lectures delivered before the Society of Arts.

with each other, each group only taking its hundred volts, while the dynamo would be giving 400 volts, and we should be thus able to go four times the distance that we should with the ordinary two-wire system, or to twice the distance that we could with a three-wire system of 200 volts. This system has been adopted in several cases abroad; even at the time of my previous lectures it had been used for some time in Hungary, at Temesvar. It has been since then more extensively introduced by one or two central stations, the most notable one being the Secteur Clichy, in Paris. The difficulty with this system of distribution lies in the fact that when at any time of the day the number of lamps upon the different groups is not equal, the groups which have the fewest lamps have the highest pressure working on them, and the lamps are too bright, while those groups which have the greatest number of lamps have the lower pressure and are too dim. Various attempts have been made to get over this trouble. I showed you in my previous Cantor lectures an arrangement which I myself had tried to elaborate, of an automatic switching of the lamps from one set of mains to the other, but I think it is too complicated, and not likely to succeed. Another plan occurred to me at the time, but the difficulties in the way of introducing it seemed so great that I did not mention it. This has been introduced in the Secteur Clichy, Paris. There is introduced at the different parts of the network what is called a compensator, which consists of four different dynamos all on the same shaft, and each dynamo is connected on one of the four groups. Suppose there is one circuit receiving too much pressure because there are too few lamps, then the pressure on the dynamo corresponding to that group is greater than the other four dynamos, and it will therefore act as a motor and be driven at greater speed than if it was quite out of the circuit. Being driven at greater speed, it raises the pressure in all the other different circuits, and thus in the circuits in the groups which have least pressure, the corresponding dynamos are acting as dynamos generating electricity, and in the groups where the lamps are fewest, they are acting as motors absorbing current and giving power to the dynamos. This is not satisfactory, the compensator requires to be continually at work, and the experience of the directors of the Secteur Clichy is that about 12 h.p. is being wasted in friction of the machine, and the consequence is it is a very wasteful system to introduce. Even though the machines are extremely perfect and require very little attention, still they need lubrication; the brushes need some attention; so combining the attention required and the waste there is in the friction of the machine, the system has not been approved, and is going to be abandoned. The alternative to which they have been driven is to use batteries of accumulators to act as compensators, put in at different parts of the network of mains—a series of batteries, say, 50 cells each, between each of the pairs of mains—that is to say, in parallel with each group of lamps. These batteries will maintain the pressure, and if there are too few lamps on one group, the current will pass through the battery and will be charging it up, and the battery will act as a regulator. They behave extremely well, but batteries are, of course, an expensive item. You will notice that this five-wire system—which would be more satisfactory and more economical—is very similar to Hopkinson's many wire system—an extension of his three-wire system, patented by Hopkinson and Edison simultaneously. The difference is that in Hopkinson's there is not a single dynamo of 400 volts, but four dynamos of 100 volts each, and they are put upon the separate groups. At the moment when the number of lamps on each group is the same, there will be no current passing through the intermediate wires, the four dynamos will be generating their 400 volts, and the current will be going in at one extreme wire and coming out at the other. When the lamps are used more on one group than another, then the intermediate wire will carry current, and one dynamo will be doing more work than another. I cannot conceive how they could have introduced in Paris an unnecessary difficulty by putting in one dynamo of 400 volts instead of four, which obviates very much the difficulties. Coming down to other high-pressure systems, the most important, and the one which has received the most development, is the alternate-current transforming system. The convenience of this is enormous. We are able to send an alternating current through an extremely fine wire to a great distance—a main one-twentieth part of the section will carry current supplying the same energy as in the low tension. Of course, it is dangerous to bring the high tension into our houses; but the transformer gives us the utmost facility, by the most beautiful contrivance, of transforming down and producing low pressure. By passing the current through one set of coils in the transformer, we do, by alternately magnetising and demagnetising the core, induce in the secondary coil—totally distinct from the primary—currents which are of low tension. This is of the utmost importance, because, in a properly constructed transformer, it is possible to ensure absolute immunity from danger, and from the high pressure entering the house. I regret that that is not always done in practice; inefficient transformers have been introduced, but there is no excuse for bad work in that way. The alternating current lends itself to distribution in another way, and this is a point which has not been sufficiently attended to in the past. The method which I have suggested is about to be adopted in the lighting of the City of London, and I think, when once it has been introduced there, it will be generally adopted in other cases.

You will remember, when I was speaking about feeders and low-pressure systems, I showed you that there was some difficulty in regulating the pressure in different feeders. There is not the slightest difficulty in this way with alternating currents. This can be done simply by the introduction of what is called a choking coil—coils of wire, in the centre of which we can introduce iron wire. By this means we are able to reduce the E.M.F. which is acting upon a feeder, without consuming energy, at the same time; and the distance to which we introduce the iron into the centre of the coil gives us the means by which we can regulate the E.M.F. on that feeder. We thus have the most perfect way of regulating the pressure in the different feeders. Another method is equally applicable, and that is to pass the current through a transformer in the central station, and take on the current from the whole of the secondary coil in the transformer, or rather less. We may switch on to different parts of the secondary coil, and thus, by adjustment, can take off current at 100 volts, and at different voltages. These two methods will in the future be of the utmost importance in electrical distribution by means of the alternating current.

The alternating current has been objected to on a great many different occasions by those who are either interested in supporting low tension for some reason, or who do not fully appreciate the merits and advantages of the alternating current. There have been certain disadvantages connected with it, which we must look to; and if we hope for the alternating current to survive as the best system, we shall wish to see these difficulties removed. The first important difficulty we need pay attention to is, that hitherto it has not been good for driving motors. This is not so serious a difficulty as it looks at first sight. The experience gained where motors have been put on lighting circuits has not always been favourable to that arrangement, and in many central stations it is found desirable to have separate machinery and separate distribution mains for the motor circuits. If the motors are not under the same conditions as the lights, and are doing at all heavy work, or are put suddenly on to a very large amount of work for a short time, such as lathes, etc., a strain is put on the electrical supply in the immediate neighbourhood, and the lamps in the vicinity become dim. In a motor circuit, the regulation of pressure to a very great nicety is not of such great importance, but in lighting circuits the regulation is of the utmost importance: therefore it is not desirable that they should be put on the same circuits. One of the chief reasons alleged for putting motors on the lighting circuit was that the load factor would be improved. This is not the case, however, as the two overlap at the busy time, the maximum amount of light being required at the same time that current is required for the motors. I believe that in the future developments of central station distribution by means of alternating current we shall have got over these difficulties entirely. The other difficulty which really needs to be overcome relates to electro-chemi-

cal operations. For these the alternate current is not very suitable. Of course, we cannot charge storage batteries, nor can we use the alternating current for electro-deposition. But current for electro-deposition is not generally let out from a central station, if it were a good plan to do so we might see a solution to the load factor problem by letting out current at cheap rates; as a matter of fact, for electro-deposition works it is cheaper to generate electricity direct than to take it from a supply company. As to storage batteries, it is very convenient to be able to charge storage batteries, but so long as our station is so managed that we do not require any reserve power, the necessity for storage batteries diminishes; and I must say, as the result of practical experience in the past, we are improving every year in the certainty of our supply of electricity, so that at the present moment there is really only an infinitesimal number of stations being called upon to supply electricity from storage batteries, and every year is diminishing the possibility of such a thing. I must say that such a supply is an advantage not to be overlooked in a well-regulated central station.

Now, I have said there will be some considerable changes in our methods of distribution of electricity by means of the alternating current. The greatest alteration which I expect will occur lies in the fact that it will be found most satisfactory from many points of view to introduce sub-stations. Up to the present it has been the custom, when using alternating currents, to put a transformer in the house of each consumer. It is in the first place somewhat costly to make separate transformers. In this, as in all other cases, if you make up a 1,000 h.p. in small units you require a very great deal more material and labour than when you make up the same in larger units. It is also inconvenient to put transformers in the houses for another reason—namely, that it is very much more difficult to regulate the pressure so as to keep it perfectly constant at all hours, because, in addition to the changes in the pressure owing to the distribution, as in the low-tension distribution, we have an actual loss in the transformer, and though a great part of this loss is a perfectly constant fall of pressure, and therefore does not affect the distribution problem, still there is a certain amount which is variable with the load; therefore we are introducing by this system an extra difficulty in regulating pressure. If we introduce sub-stations from whence the low tension is distributed, the pressure regulation can be done by attendants, provided always that we make them sufficiently large to make it worth while to employ attendants. There seems not the slightest doubt that we shall be able to adjust this in another manner, by making the transformers self regulating to a certain degree, so that it will be possible to place these large sub-station transformers in underground vaults, say, in places where they only require very occasional inspection, and where they do not require to have continual attendance. There are several inventions which have been made in this direction, and I had hoped to show you some which have been introduced by Mr. Ferranti, and he himself would have been most willing, but unfortunately, as you know, there are some troubles connected with foreign patents, and the possibility of too much being divulged prevents me from showing this apparatus. You can perfectly easily see that it is possible to arrange some sort of automatic switch, so that when the demand for current increases, an additional transformer will be switched into the circuit, and when the current falls off this switch will act in the opposite direction and put in a smaller transformer. It is also possible to wind our transformers, both primary and secondary, with more than one wire, and to have an automatic arrangement by which these coils shall be put in series or parallel, primary and secondary simultaneously, according to the different demands for current; that also will get over our difficulty. The effect of such changes will be to make the transformers work at their economical load. There is always a loss in a transformer due to hysteresis, and that loss is pretty constant whatever the demand for current may be. Now, by proportioning the size of our transformer to the load required, we are able to make the hysteresis loss a small proportion of the total current required to keep the transformer working at its efficient load.

At the present time, with a transformer in every house, transformers are working in a very inefficient manner during the greater part of the time, both when the load is light and during the daytime, when no secondary current is being taken at all. These transformers must always be supplied with current, and even during the daytime consume an appreciable amount of energy—that used in overcoming the hysteresis of all the transformers over the whole town. But with our sub-stations supplying secondary low tension to the mains, we shall have only a very small number of transformers at work during the hours of light load, and the consequence will be that each transformer will be working in an efficient manner during the whole 24 hours. I think we may safely look for an average efficiency of 90 per cent. during the whole of the 24 hours. I may say the feeling at the present time is very general among engineers that sub-stations ought to be introduced, instead of having transformers in every house.

If we are to introduce these sub-stations, it becomes necessary to review the whole system of distribution, and consider whether we are working in the right direction. There is one point requiring radical modification—i.e., the frequency of alternations used in connection with our distribution. When the pioneers in this line started work it was of course looked upon as a great feat to get nearly the whole of the energy transformed and supplied in the secondary circuit, and it was a great feat to do this by means of cheap apparatus. It was impossible to do this cheaply and economically unless we used very small transformers; and the only way in which we could use very small transformers, with high pressures of 1,000 volts, was by having rapid alternations, and, consequently, the pioneers used dynamos which gave very rapid alternations and a very small transformer. The result is that you get a very considerable consumption of energy due to the hysteresis of this transformer.

Now, when we come to use sub-stations with very large machinery, the economy which is to be gained by using high frequency is not nearly so large, not nearly so well worth considering, as it is when we are dealing with scattered lighting, and able to put transformers more economically in every house. For this reason, then, I think it would be desirable to reduce the frequency of our alternations as low as the frequency of the alternations in an ordinary continuous current dynamo armature. That is to say, reduce from 130 and 80 periods per second down to something like five or 10 periods per second. There are other reasons why we should use low frequencies. When we have secondary mains of that large section of copper used in our low pressure systems, it is only with difficulty that we can force a current of high frequency through it.

High frequency has a remarkable effect on the conducting qualities of large conductors. The whole of the current is forced towards the outside of the conductor, and makes the inside of the conductor almost useless as a means of carrying the current. It is only by diminishing the frequency of our alternations that we shall be able to get over this very serious trouble, which will attack us as soon as we have low tension mains carrying alternate currents. There is another advantage in using low frequency currents, and that is, the problem of electromotors is immediately solved.

It has been a wonder to many why we could not use continuous current motors with the alternating current, if the field magnets were made of laminated iron. It was said that a current in the one direction drives the motor in the one way, and if we reverse the direction of the current, it still goes on in the same way. Why should not this happen with an alternating current? So it would, but the employment of an alternating current to magnetise the field magnets of these motors involves an enormous counter E.M.F. set up in the coils round the field magnets, as the effect of what is known as self induction; the consequence is that a great proportion of the volts which we supply to the motor is taken up in magnetising the field magnets. I have calculated out the particular case of a 10 h.p. motor working at 100 volts, and I find that though the field magnets be laminated in the best possible way, this motor, when worked by an alternating current, would

require 99 volts in addition to the 100 volts actually needed when worked with a continuous current—practically 100 extra for exciting the field magnets. When that motor is used with a continuous current, only ¾ volt is required for magnetising the field magnets, so that you would have to work at 200 volts to supply the motor with an effective E M F of 100 volts, and yet at the present moment motors of that character are being used largely in America on lighting circuits, for some purposes where the power used is small, so that an output of 30 or 40 per cent. of what might otherwise be obtained is ample for the purpose. I have calculated that if you were to reduce the frequency to five periods per second, the volts required in that case for exciting the field magnets would be six instead of ¾ volt.

We should thus be diminishing the output of the motor down to 90 per cent., which is not a serious thing, and be making the use of such a kind of motor practicable. We know perfectly well that alternating current motors are being developed by other means, and that some of them are far superior in practical working to any of the continuous current motors; and, consequently, the direction in which this part of the subject will be extended is almost certainly in the development of these new types of motors, which have attracted so much attention elsewhere. Even for that class of motor, too, there is no advantage in having high frequency, and it will be a distinct gain to have low frequency. Low frequency will also enable us to introduce a commutator in such a way as to convert alternating current into continuous, and that will enable us to charge storage batteries. At the present time the only way of doing this with alternating current is to employ an alternating-current motor and cause it to drive a continuous-current dynamo machine. By that means we are able to charge storage batteries; but by introducing low frequency the advantages are so great that I think it is most desirable, when we are considering the question of using sub-stations with large transformers supplying the secondary mains, that we should also consider the other alternative of using low frequency, and a commutator to convert the alternating into a continuous current. The only reason why we use high frequency is the large number of transformers; it economises their construction, and we are able to have a cheaper transformer, but you will see that that *desideratum* is diminished when we come to the sub-station method of distribution.

Other systems of establishing high tension have been proposed, the most important that has received attention being the continuous-current transforming system, which consists in sending high tension continuous current from a central station to a distant sub-station, where the current is received and passed through a motor, which serves then to drive a continuous-current dynamo of low pressure. That dynamo then serves as a source of energy to the neighbourhood around, supplying the mains in its immediate neighbourhood. We can have several of these sub-stations, so that from one central station we are able to distribute our power in the form of high pressure electricity to several distant points, and then to produce low-pressure electricity and distribute through our mains. These combination machines, of motor and dynamo combined, can be made of a very high degree of efficiency owing to a remarkable fact. The efficiency of a dynamo or motor is impaired by the reactions produced by the currents in the armature, and these reactions, in the case of dynamo and motor, are in opposite directions. If now we wind a high tension winding on an armature to serve as that of a motor, and on the same armature we wind a low tension winding which is to act as that of the generator for the low-pressure supply, and put a separate commutator and a separate pair of brushes to each of these windings, we have the same machine acting as a motor and as a dynamo, and we have an absence of those armature reactions which would be produced either by the motor winding or by the dynamo winding alone, because they are produced in opposite directions by the two windings when we use one as a motor and the other as a dynamo, consequently we have an apparatus which is extremely efficient and useful.

(*To be continued.*)

ELECTRIC LIGHT AND POWER.

BY ARTHUR F GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

II.—MOTIVE POWER.

Sources of Power.

(*a*) *Artificial.*—People look considerably surprised when they are informed that the production of electricity, and hence the electric light, is attendant with the consumption of a good deal of power; that, for example, a steam engine yielding six brake horse-power will only run 60 incandescent lamps of 16 c.p. at the utmost. They all know that there is such a thing as a "battery," or a "cell," and have a dim recollection that zinc or some other metal is put into a jar containing some acid, or chemical solution, and that from this simple apparatus you can obtain an electric light—as you can in a fashion—so when they learn that a boiler and steam engine is required to run 50 or so glow lamps, or half-a-dozen arc lamps, they cannot understand the reason. It is interesting to draw a comparison between the power generated by a battery and by a dynamo. For every pound of coal burnt per hour under the boiler, ¼ b.h.p. can be produced, and this would run three glow lamps of 16 c.p. each; if a battery were employed to supply the same amount of electrical energy for the same time, it would be found that ½lb. of zinc would have to be burnt. The cost of the coal may be put down at less than $\frac{1}{10}$th of a penny, whereas the cost of the zinc is twopence, or the fuel for a battery is 20 times more expensive than the fuel for a boiler and steam engine. This is why batteries are entirely out of the question for generating large quantities of electrical energy, and even if the cost of the battery fuel was much less, it is doubtful whether they could be of much practical use on a large scale. The chief way to obtain power is by burning some material either in a solid, liquid, or gaseous state. As a solid, coal is burnt under a boiler, and the heat so obtained utilised in converting water into steam, at a greater or less pressure. As a liquid, petroleum or other oils can be cited, which are used the same way as the solid fuel. As a gas, coal gas is compressed and exploded, the explosion yielding energy, arising from the expansive force of the gas. Hence, the steam engine, oil engine, and gas engine, using respectively a solid, a liquid, and a gaseous fuel, belong to the class of artificial sources of power, and bear witness to the ingenuity of man.

(*b*) *Natural.*—Besides these, there are the great natural sources of power which engineers are continually directing and subjecting to their use—a mountain torrent, a swift river, a waterfall, wherever a body of water is moving from a higher to a lower level—all will yield a continuous supply of energy, in great or small quantities, according to the rapidity and volume of water rushing down. Then there is the ebb and flow of the tide, which is the greatest source of wasted energy on the globe. Twice daily do the billows surge and thunder on the shore, and it is only when one gazes, fascinated at the wide glittering expanse of seething waters, as they hurl themselves on a rock-bound coast, that any slight idea can be formed of the terrific forces at work, millions of horse-power being wasted every mile of coast they encircle. So truly the foam flakes, the expressive token of all this energy, possess as much value as if they were solid flakes of silver, could but this immense display of power be utilised! Attempts have already been made to store the force of the tidal motions, and, at the present rate of invention, we shall undoubtedly in the near future arrive at the ways and means of doing so. Another natural source of power is the wind, from the gentle breeze to the fierce tornado. This power has been used for driving ships for ages, and although steam has supplanted most sailing ships, still a good number remain. On land the many windmills on elevated ground scattered all over the country indicate how its power is utilised, although its services are very fitful and erratic.

Conservation of Energy.

All energy on the face of the earth has its origin in the sun. Coal is the product of the sun's rays acting for countless ages on vegetable matter, and the undergrowth of primeval forests, the heat of the sun thus being stored. By digging out the coal and burning it, we regain the heat which was dissipated ages ago. In the dense and boundless

forests of Central Africa and other unexplored parts of the world, the sun is probably storing up for us untold wealth, ready for the future use of the denizens that will some day inhabit the land. It is the same with water power; it is the energy of the sun's rays which evaporates the water in our seas and lakes, and this water vapour, ascending into the sky, is wafted by the winds hither and thither until, coming into a strata of cool temperature, the vapour condenses into a rain cloud, and thus returns to the earth's surface in the form of rain. When the rain falls on elevated regions, such as mountain summits, a mountain torrent is produced, which as it dodges and dashes down to the plains below mingles with other torrents, and so the body of water accumulates until it meanders over the plains on its way to the sea, a broad, shining river; and so the cycle of changes go on, the water taken up into the clouds from the sea being caused to return again. Again, it is the sun's rays which produce winds: the heated air rises upwards, and immediately a rush of cold air takes place to fill the space vacated.

From the above general remarks it will be seen that really there is no waste of energy. The word "waste" is only used to express that which we cannot utilise for our own purposes, hence there is only a transformation of energy going on from one form to another form. This great fundamental law of nature is termed the "conservation of energy," and it must be implicitly accepted, and thoroughly recognised and understood when dealing with "electric power," just as it should be when dealing with any other subject which treats of energy. To make this statement more emphatic, let us follow the several steps of transformation of energy that take place in reproducing the light of the sun in the form of an electric lamp. First, the heat is stored as coal, which has been very aptly termed by Mr. Preece "preserved sunbeams"; coal being burnt, evaporates water into steam, steam drives the steam engine, and thus this third transformation consists of changing the energy of heat into mechanical power. By causing the steam engine to drive a dynamo, a fourth change occurs, the mechanical power being now converted into electrical power. The final transformation occurs when the electric current in passing through the lamp filament generates such intense heat that it produces light. Hence there are five transformations of energy between the light of the sun and that of the electric lamp. It may be asked, Why is it necessary to have so many changes, for each change signifies a loss, according to the commercial efficiency of the machines or converters employed? and, Why cannot we obtain electricity direct from coal, without these intervening converters? The answer is that our present state of knowledge will not permit us. The problem has been attacked, but so far, without the slightest practical value arising. Five different transformations is a good number, and a roundabout way certainly, but as we see no other way, we must put up with it.

The following remarks give an idea of the losses that occur in each converter, at the present state of efficiency:

Of the total heat energy contained in burning coal, only 50 per cent. can be said to be utilised to evaporate water into steam, hence the boiler has an efficiency of only 50 per cent.

Passing on to the steam engine, it may be said that the very best steam engines built only utilise from 9 to 10 per cent. of the heat energy evolved by the burning coal, and since the efficiency of a boiler is 50 per cent., this makes the efficiency of the engine 18 to 20 per cent., allowing the low figure of 2lb. of coal per brake horse-power—a performance very rarely met with. On allowing 4lb. of Welsh coal per brake horse-power, the efficiency of the engine is brought down to 9 or 10 per cent.—that is to say, that only 10 per cent. of the heat energy of the steam admitted into the cylinders is converted into available power, and when calculated from the heat energy of the coal burnt under the boiler, the amount utilised becomes 5 per cent. However much boilers and steam engines may be improved it cannot, by any possible way, prevent this source of power from being terribly wasteful. On theoretical grounds, the employment of fuel in the form of a gas (such as coal gas) and oils (as petroleum) to drive internal-combustion engines, known as gas engines and oil engines, gives a much higher efficiency than the best-made steam engines and, sometimes twice the efficiency; but since this form of fuel is more expensive than coal, steam power is most economical for large power.

We have now reached the third converter—the dynamo, the machine that transforms the mechanical power given by the driving wheel or driving shaft of the engine into electrical power. Concerning the marvellous state of efficiency to which a modern dynamo has now been brought, it is difficult to find a parallel example. No less than 96 per cent. efficiency has been obtained in these machines for transforming mechanical energy into electrical, and every dynamo on the market can point to 87 per cent., and, in addition to this, the small percentage of loss can be entirely accounted for and measured, thus proving to the hilt the law of the conservation of energy. The fifth and last transformation takes place in the electric lamps, where the electrical current spends its power in heating up the carbon filament of the lamp to an incandescent state, and producing light. The energy that caused the sun to shed out light and heat thus, through numerous changes, reappearing in the light and heat of a miniature sun or electric lamp.

The commercial efficiencies of the several converters are tabulated below, taking 4lb. of coal for 1 b.h.p.

—	Heat units.	B. H. P.	e	E
			%	%
4lb. of coal burnt per hour produce...	58,000	22·4	100	100
Amount of heat utilised by boiler......	29,000	11·2	50	50
" " " " engine ...	2,842	1·0	9·8	4·9
" power " " dynamo..	2,643	·93	93	4·55
" " " " lamps ...	2,590	·91	98	4·45

e denotes the commercial efficiency of each converter—that is, the amount of work done by the machine, as compared to the power put into the machine. E denotes the "commercial efficiency" of each converter as compared with initial power supplied by the coal.

The last transformation—*i.e.*, converting the electricity into light—is given as with a loss of 2 per cent. This loss is entirely dependent on the distributing wires, and so can be made anything; but 2 per cent. for short distances, say a radius of 100 yards, is sufficient; in fact, is very high. By running the electric lamps close by the dynamo no loss, practically, is incurred, because there is no length of wire between the two. There is thus a total commercial efficiency of only 4·45 per cent. between the heat energy of the coal and the heat energy as it appears in the electric lamps. This is when steam power is used. No wonder that people strive to obtain electric power direct from burning coal, without the intervention of the wasteful steam engine.

(To be continued.)

WAVE PROPAGATION IN MAGNETIC MATERIALS.*

BY PROF. FITZGERALD.

Taking the particles as a set of magnets held in place by one another's mutual attractions, and assuming as a first approximation that the moment on any needle is proportional to the sum of its own and its immediate neighbour's rotations, then the velocity of proportion of a wave is given by

$$v = 2\, N_0\, \lambda \cos \frac{\pi l}{\lambda};$$

where N_0 is the frequency of vibration of each magnet when its neighbours are fixed, λ is the length of wave generated, and l is the distance between the centres of neighbouring magnets, and to determine the frequency corresponding to a given wave-length, we have

$$N = 2\, N_0 \cos \frac{\pi l}{\lambda}.$$

From this we see that N cannot be greater than $2\,N_0$, and that in that case $\lambda = \infty$, while that for smaller values of N we have the wave-length decreasing until $N_0 = 0$, when $\lambda = 2\,l$, which is the minimum wave-length. This last is obvious, because when the magnets are swung very slowly from side to side, each takes the phase opposite to its neighbour and consequently $\lambda = 2\,l$.

Thus it appears that the wave-length will be very small unless N is comparable with N_0.

* Paper read before the British Association at Edinburgh.

In order to calculate N_0, we may estimate roughly the quantities involved. If we take each magnetic particle to have $l = 10^{-7}$; and if we assume such strengths of poles that the lines of force per square centimetre from them would be 1,000, we can estimate for a material whose density is 7 the moment of inertia of its elements, and the moment of each as a magnet, and thus I have very roughly estimated the time of vibration of each element, and find $N_0 = 1{\cdot}6 \times 10^{-8}$. If the elements are estimated as smaller, this frequency will be much increased, proportionally to the second power of the dimensions, so that if the size of the molecules were 10^{-8}, the frequency would be about 10^{10}. If, however, the strength of the poles decrease, there will be a corresponding decrease in the frequency, so that we must not take the calculation as anything but very rough indeed. It would appear, however, that frequencies comparable to those of Leyden jar discharges might produce waves of measurable wave-length, and that waves of a frequency comparable to that of light would probably not be propagated at all.

This agrees with Prof. Dewar's recent observations that light is sensibly completely polarised by liquid oxygen, a transparent magnetic medium, and with the fact that a strongly magnetic medium like iron seems not to have any very obviously peculiar properties in respect of the reflection of light, except those very minute, and consequently, in all probability, secondary phenomena, due to its being magnetised, and which Mr. Kerr so wonderfully discovered.

It would also account for the fact that Leyden jar discharges are not too rapid to create absorption of energy by iron, and might lead us to expect that possibly liquid oxygen itself may have a corresponding powerful absorbing power for some very long waves, although it is so good a non-conductor.

It also accounts for the want of success that has attended attempts to measure, by interference, the rate of propagation of waves of low frequencies in iron, for the length of such waves becomes comparable with the inter-molecular distances, and so out of reach of the means of observation used, the velocity of propagation being very low.

These considerations would also lead one to expect that the elementary magnets could easily follow much more rapid magnetisations than occur in transformers, without any sensible change in the nature of the law of magnetisation. This naturally leads to the question as to how far the magnetic motions may be damped, because it may very well be that there is no free period of vibration, and in that case this investigation would fail. A comparatively slight damping of motion would stop such rapidly vibrating elements.

This investigation only deals with small magnetising forces; the large one usually dealt with in transformers are propagated much more like an explosion than like a wave.

COMPANIES' MEETINGS.

DIRECT SPANISH TELEGRAPH COMPANY.

The thirty-eighth ordinary general meeting of this Company was held on Tuesday at Winchester House, Old Broad-street. The report of the Directors stated that the accounts for the half-year ended June 30, 1892, showed, after providing for debenture interest, a balance to the credit of profit and loss of £5,438. The traffic receipts showed a decrease of £45, as compared with those of the corresponding period of 1891. They might, however, be considered satisfactory, as in the half-year of 1891, with which they were compared, the present reduced tariff had not come into force. The working expenses were £170 in excess of those for the corresponding period of last year. The Company's cables and the land lines in connection with them had continued in good working order throughout the half-year. After putting the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounted to £2,938. Out of this amount the Directors recommended the payment of a dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend at the rate of 4 per cent. per annum, free of income tax, on the ordinary shares. There would then remain a balance of £441, which would be transferred to the reserve fund in part repayment of the sum of £2,736 taken from that fund towards the repairs of the Falmouth-Bilbao cable in November, 1891. The reserve fund would then amount to £29,827.

The Chairman, in moving the adoption of the report, said at their meeting in March he called attention to the reduction of the tariff by one halfpenny per word, and said if the traffic did not increase it would mean a loss of £1,700. But the growth of the Spanish traffic, resulting from the commercial treaty with Spain, had continued, and they had telegraphed 43,000 more words than in the corresponding half of last year. From 1886 there had been a continuous growth each year, so that they did not take a despairing view of the loss of a halfpenny per word which the conference had inflicted on them. This half-year there had been an increase of 10,000 telegrams, or 130,000 words; but he was obliged to say that this was not the result of a normal growth, as the merchants used their lines very freely, with the object of getting their goods into Spain before the old treaty expired. Business seemed to force merchants more and more into telegraphy, and he hoped that this would prove the case, for it was the mainstay of their revenue. In his opinion telegraphy did best when the business pendulum swung both ways with a profitable result. Since the treaty expired on the 30th of June, the growth of their traffic showed an increase. The reduction in the length of messages by codifying had ceased, and they were now one word per message better than they were a few years ago, when there seemed to be no end to the ingenuity of code-makers. He would leave the future to itself but three minutes to Bilbao and 20 minutes to Madrid for a message, came as near dealing with one's foreign correspondent in the same room as could be desidered. They were looking forward to the renewal of their 6 per cent. debentures in 1894 at a lower rate, but that would depend on the state of their revenue. Much would depend on their freedom from breaks and extensive repairs; but the Directors' policy would be to maintain their shares as a good investment with as little fluctuation as one saw among the better securities in the lists of the London Stock Exchange. They were making a very fair revenue, and must be satisfied with it. He had no idea what might happen at the next conference, which he was glad to think was still three years hence, for the ideas of the Post Office and of European Powers might be modified in the meantime. At present they were talking, and he hoped that it was only talk, of a uniform continental tariff; but a good many Governments were losing by their telegraphs. The Australian colonies wanted to raise the tariffs, and he hardly expected that there would be any great *furore* to lower them. The tariffs could not be reduced without loss of money, and 4 per cent. was not too much—in fact, not enough—to pay for this class of enterprise.

Mr. Edmund Ettlinger seconded the adoption of the report, which was agreed to, and the meeting concluded with a vote of thanks to the Chairman.

LEGAL INTELLIGENCE.

IN RE HOBBS AND CO.

In the High Court of Justice, Chancery Division, before Mr. Justice Barnes, on Wednesday,

Mr. Marten, Q.C. (with him Mr. Herbert Burne) applied on behalf of creditors that the firm of Hobbs and Co., builders, should be wound up.

Mr. John Chester applied on behalf of the American Elevator Company, who had also lodged a petition for the carriage of the order. He said that his clients' claim was for £32,000, which was secured by mortgages. The firm were the builders of Whitehall-court and of the large flats recently built near the French Embassy, and called Hyde Park-court.

Mr. Ford supported the petition on behalf of the Kensington Electric Lighting Company, who had arranged to light the buildings.

Mr. Brodie Cooper and Mr. Eldridge also appeared.

A winding-up order was made.

BUSINESS NOTES.

Warminster.—The new fountain at Warminster is to be lighted by electric light by Mr. Mark Hill, at £15 a year.

Globe Telegraph and Trust.—An interim dividend of 1s. 9d. per share has been declared by the Board, payable on the 18th prox.

Notice of Removal.—The registered offices of the General Electric Power and Traction Company are now at Worcester House, Walbrook, E.C.

Windermere.—The application by Mr. Fowkes for leave to lay an underground cable for electric light in Windermere was deferred for guarantee that the work should be permanent.

Westminster Electric Supply Corporation, Limited.—The offices of this Company have been removed to the central station at Eccleston-place, Eccleston-street, Belgravia, S.W.

Ullswater.—The General Electric Power and Traction Company have completed installations by which the Greenside Silver Lead Mines at the head of Ullswater will be lighted by electricity.

Dolgelley.—At the meeting of the Dolgelley Local Board, the clerk reported that the Lighting Committee had come to terms with Mr. Hall, of Liverpool, to light the town with electricity.

Western and Brazilian Telegraph Company.—The receipts of this Company for the past week, after deducting 17 per cent. payable to the London Platino-Brazilian Company, were £3,584.

West India and Panama Telegraph Company.—The receipts for the half-month ended September 15 were £2,146, against £1,844. The May receipts estimated at £5,895, realised £5,901.

Otterbourne.—Tenders for the lighting of the Southampton Water Works at Otterbourne must be sent in by the 27th inst. Mr. J. G. Waldridge, of 9, Victoria-street, is the electrical engineer.

New Telephone Company.—The offices of the New Telephone Company, Limited, will be removed on the 29th inst. from 110, Cannon-street, to the Telephone Exchange, 58 and 59, London-wall, E.C.

Chertsey.—The Board of Trade have written to the Chertsey Sanitary Authority agreeing to an extension of time as requested by the Weybridge Electric Lighting Company, in order to arrange for a continuance of the supply of current to Chertsey.

Greenock.—On the rebuilding of the Orchard sugar refinery at Greenock, recently destroyed by fire, it has been resolved to introduce the electric light. The work of installation has been entrusted to Messrs. Norman and Co., Limited, of Glasgow.

Fleetwood.—The Fleetwood Commissioners have decided not to entertain the offer of the gas company to purchase the works for the town. They think electricity better worth their attention, and four estimates for lighting the town by electric light have been obtained.

Oxford.—The Oxford City Council have authorised the annual expenditure of £210 for three years, in addition to the present cost of lighting, for the purpose of introducing the electric light for street lighting. Eighteen arc lamps will be erected, to displace 56 gas lamps.

City and South London Railway Company.—The receipts for the week ending September 18 were £744, against £684 for the same period last year, or an increase of £60. The total receipts for 1892 show an increase of £785 over those for the corresponding period of 1891.

Wrexham.—The estimate from Mr. Sillery, electrical engineer, Chester-street, Wrexham, offering to connect the Guildhall with the water works offices, and with the Regent-street office of the town clerk by telephone for £25. 10s., including supervision for two years, has been accepted.

Eastern Extension, Australasia and China Telegraph Company.—The Directors have declared an interim dividend for the quarter ended June 30 of 2s. 6d. per share, free of income tax, payable on October 15 prox. The share register will be closed from October 7 to October 14, both days inclusive.

Shiplighting.—The "Iona," built by Messrs. Gourlay Bros. and Co., of Dundee, for Messrs. W. Thomson and Son, is designed for the Canadian cattle trade, and fitted with the latest improvements for the safety of the animals. Special attention is paid to lighting, and the ship is lighted throughout with electric light.

Rockhampton Gas and Coke Company.—Messrs. Wm. Coward and Co., of 11, Queen Victoria-street, E.C., notify that they have received from the Rockhampton Gas and Coke Company, Queensland, the dividend for the six months to 30th June, 1892, due to the English shareholders, at the rate of 10 per cent. per annum.

Dundee Tramways.—A meeting is to be held at Dundee to discuss whether the tramways are to be taken over by the Corporation and worked for the benefit of the community. Dundee is shortly to have electric supply, and the probable change of ownership of the tram lines may lead to the introduction of electric traction.

Colombo.—The Government has decided to have the electric light supplied at Colombo to the post office, the Queen's House, and the wharf, while the hotel proprietors have sanctioned the use of electric light. Messrs. Siemens Bros. are taking up the matter. The lighting of the streets is not likely to be carried out at present.

Coatbridge.—Messrs. J. E. H. Gordon and Co., Limited, of 11, Pall-mall, have obtained a contract for the electric lighting of Coatbridge, and are proceeding to erect a station of 3,000 lights capacity with all the necessary street mains. The machinery is in hand, and it is expected that the work will be finished in the early spring.

Siemens and Halske.—Tales are rife of enormous endeavours made by the combined Edison-Thomson-Houston Trust, in America, to buy all the impending Siemens and Halske Company, of America, repaying the quarter of a million already spent, and goodness knows how much more as a bonus. But without avail—competition will still be there, and stronger than ever.

Pulsometers.—The Pulsometer Company have now adopted what they termed the "Grel" arrangement to their pulsometers, by the use of which the steam is automatically cut off before the end of the stroke, allowing the steam to act expansively, to the saving of some 40 per cent. of the steam. These peculiar pumps are always useful in engineering works, and will now be even more advantageous.

Burnley.—The Corporation of Burnley invite tenders for the supply and erection of machinery for their central electric station, and for cables in the streets, as a whole or in parts brought livestone, as follows: boilers, fuel economisers, engines, travelling cranes, dynamos, accumulators, switchboards, cables. Specifications, forms of tender, and other information may be obtained from Mr. J. P. Leather, Gas Works, Burnley, and the tenders are to be sent in by October 26th.

Bradford Tramways.—The Bradford Tramways Committee report that the engineers of the committee lead them to believe that electric traction, like the cable system, would be too costly for them to adopt, and that steam traction would be the best system. It is a pity some electrical firm could not convince them of the advantages of electric traction, for a entirely opposite view has been taken in America, where whole sets of steam and cable cars are laid aside for electric cars.

Wigan.—At Wigan Town Council a letter was read from Mr. Alfred Peck, the managing director of one of the largest local undertakings, saying he would like to take the electric light, but not at 6d. a unit, which was nearly double the price of gas. Mr. C. B. Holmes, chairman of the Gas Committee, pointed out that 6d. was considerably less than was charged at most other towns, and that he thought supply even at 6d. would entail a loss during the first year, and a reduction could not be conceded till this loss had been made up.

Windsor.—A contract has been signed between Messrs. J. E. H. Gordon and Co., Limited, of 11, Pall-mall, and the Windsor and Eton Electric Company, for the erection of an electric light station at Windsor, and for the running of mains along the High-street and a portion of Peascod-street. The work has already been put in hand, and it is expected that the light will be supplied before Christmas next. The installation is only a small pioneer work, but arrangements are made for a large extension as soon as the success of the first instalment has been demonstrated.

Bolton.—A movement is on foot for the extension of electricity in Bolton, and six tenders for electric installations have been submitted to the Gas Committee and referred to the mayor (Alderman Nicholson), the chairman (Alderman Miles), the vice-chairman (Alderman Broughton), and Councillor W. Cooper, and report thereon to the committee at an early date. We understand, says the *Bolton Journal*, that it is intended to fix the installations in shops in the vicinity of Town Hall-square and streets leading thereto, and if successful to extend electricity throughout the borough.

Leicester.—It is expected that the electric light question will be now made a prominent one in local politics at Leicester. For two years it has been in abeyance, and the time of consideration granted to the committee will elapse in a couple of months. Tenders have been invited, and the sub-committee have opened and considered these, for laying the mains in the centre of the town. In all probability, the committee will recommend the Council to carry out the terms of the provisional order for supplying light in the town, but nothing definite will be done before November.

Sutton Coldfield.—A set of "Victor" turbines has been supplied by Mr. F. Nell for the Sutton Coldfield Corporation at Blackroot Pool, Sutton Park. The turbines are housed in a handsome wood chalet, and drive a stone breaker and saw bench. Alderman Evans said he thought the use of the machinery should not be limited to these uses, but that sooner or later they should be able to test its illuminating power—he meant that they would be able to light the Town Hall by electricity. He was sorry their finances would not allow them at present to adopt this system, but the time would come when they could carry out this project.

Belfast.—At the bi-monthly meeting of the Belfast Harbour Board on Tuesday, the question of lighting the harbour by electricity was discussed. Mr. Greenhill suggested it. Mr. Wolff also spoke strongly in favour of some steps being taken in this direction, saying it was almost a disgrace to Belfast that she alone almost among the important ports of the United Kingdom and of Europe was not supplied with the light. The matter has been referred to the Works and Traffic Committee for enquiry and report. We trust that some of our enterprising firms will take care that the matter does not lapse, and that the Harbour Board will be furnished with all the information required.

Temporary Lighting.—A very successful temporary installation of the electric light was carried out by Messrs. Rawlings Bros., of 82, Gloucester-road, on Thursday last week, the occasion being a garden party given by W. Burdett-Coutts, Esq., M.P., at Holly Lodge, Highgate. The lighting was effected by incandescent lamps run off Epstein accumulators, type X., three cells, consisting only of one positive and two negative electrodes, and which, owing to the small space they take up, their large storage capacity and almost unlimited range of discharge, are admirably adapted for such purposes. Messrs. Rawlings Bros. were much complimented by host and guests on the brilliancy and steadiness of the light and the efficacy of the switching arrangements.

Heckmondwike.—The answer from Mr. Hutchinson, C.E., about the £10 cheque for consulting services was read at the last meeting of the Heckmondwike Board. It stated that the £10 was to be paid if the plans were not accepted, but only be taken as part payment if the plans were carried out. It referred to the work and visits done in preparing specifications, with reference to the professional reputation of the writer, and concluded by offering to free the Board from liability if the documents were returned. The letter was referred to the General Works Committee. An offer from an electric lighting company to light the town for a period of six or ten years was held over. On Monday the Board adopted by an overwhelming majority the resolution authorising the construction of the needful plant for a central station and the application to the Local Government Board for sanction to borrow the necessary money—about £6,000.

Swindon.—The committee appointed to consider the purchase of the gas works cannot recommend this course. Mr. Morris pro

posed the committee should be empowered to ascertain the cost of electric light. Mr. Hinton thought Swindon a town peculiarly fitted for electric light. The clerk produced a tabulated list of the cost of lighting by electricity in other towns. Questions had been submitted to other authorities, "Do you find electric lighting cheaper than gas?" Most of the replies were that it was dearer, and in one instance double the cost, but the superior light far outdistanced the cost. In one instance it was cheaper, but there it was worked by water power. The chairman and deputy clerk suggested that the whole matter should be referred back to the committee for further consideration, and in the meantime they might ascertain the probable cost of lighting the town by electricity. This was agreed to, a majority of the members voting for Mr. Morris's proposition.

Train Lighting.—The Midland and the other great railways with lines running out of London are prepared, we are told, to follow the example of the Metropolitan and provide electric lamps for the use of their passengers. It is not intended at present to displace the gas, and this can be done by making the passengers desirous of a better light pay for it themselves by a penny in the slot arrangement. But it is not unlikely that the gas may be displaced eventually. The lamps which are being prepared for use on the main lines will be installed at the outset only in trains running long journeys. The batteries will be charged with a supply of electricity sufficient to provide a continuous light during two days, so that they will not require recharging until the trains return to London. This departure is a significant one for the makers of secondary batteries, for it shows that the smaller sizes of cells are likely to be used in very large quantities. Small cells seem likely to prove one of the most important branches of the storage battery trade, and the railway companies one of the principal customers.

Bradford.—The half yearly financial statement of the Bradford Electricity Department was presented by Alderman Priestman at the meeting of the Town Council last week. The accounts were for the half-year ending June 30 last. The total expenses on revenue account during the six months were £1,573 and the total revenue £3,216, leaving a trade profit of £1,642. The interest paid on loans out of this sum amounted to £678; and the contributions to the sinking fund were £577, leaving a net profit of £387. At the end of the present year the Corporation would have contributed £3,027 to the sinking fund since the construction of the works. Up to the present time the actual amount contributed to that fund was £2,449. The total liabilities at present in respect of loans were £42,542; and the floating liabilities amounted to £47,896. There were also £400 excess of assets repaid through the sinking fund, and £2,750 was in the bank on sinking fund account. Up to the present time there had been a total loss since the commencement of the works of £799. There had been expended on capital account during the half-year £5,130, and under the heading of floating assets, there appeared in the accounts a sum of £1,029 in respect of sundry debtors and £165 in respect of sundry materials, bringing up the total amount of floating assets to £1,194. The total assets on the capital account were £49,615. Since the commencement of the works there had been paid in interest and on sinking fund account £5,625. The trade profit which had been made amounted to £4,825. There was a loss of £1,079 on the first half year's working; in the second half-year, £732; in the third, £315; and in the half year ended June, 1891, £30, the total being £2,157 6s. 8½d. At the end of December last there was a net profit of £970; and at the end of June of the present year it was £387. If the total net profit were deducted from the total net loss it would show a net loss of £799 still to be made up. He thought a considerable portion of this sum would be made up before February or March, when the next half year's accounts were presented. The accounts were adopted.

Electric Power in Tasmania.—A number of shareholders of the Australasian Rights Purchase Association, Limited, met recently to inspect the water motive power for generating electricity to supply light and power to the mines at Mount Zeehan and Dundas, Tasmania. The plant is as follows: It comprises 262ft. of piping with an intake of 7ft. 3in. in diameter, gradually reduced to 15in., off which two nozzles are taken of a 4in. diameter each, to play upon a Pelton wheel which has a diameter of 5ft. The test pressure of the pipes being 178lb. to the square inch, and a working pressure will be 100lb. to the square inch, thereby giving a result of 900 h.p. to generate electricity. From this station electricity will be transferred by a wire on poles to mines within a radius of 10 miles, which power will be available for the purposes of lighting, haulage, boring and pumping. The scheme originated from the extreme cost of mining in new districts owing to the want of roads suitable for the cartage of machinery. The only means of avoiding such heavy expenses was by the application of electricity. Having taken up the water rights and obtained a Bill through the Tasmanian Parliament, contracts were entered into with Mr. Wadey to supply the whole of the water power plant. The electrical portion of the scheme is now being taken in hand, and it is anticipated that it will be completed by the time the water power portion was in position. Mr. Musgrove, of the London Electrical Storage Company, said he was pleased to be present to have an opportunity of assisting to place before the Australian public the great advantages and manifold purposes that electricity could and would be applied to in the near future and trusted that his remarks regarding the present venture would be received in the spirit intended—viz., the universal benefit of all. Firstly, he trusted that the Australasian Rights Purchase Association would exercise great care in adopting electrical appliances, that as progress was made in electrical science such initial works would be capable of embracing all new ideas without having to reconstruct or reorganise the whole plant to meet such requirements. He instanced the necessity of plant that would be suitable for supplying lighting power for stamps, boring, blasting, depositing of metals by electricity, which would in the near future play a most important part in the mining world. The mine owners of Zeehan and Dundas are prepared to take the power provided the Company would give practical demonstration that it was cheaper than other motive power. Mr. Marks described a visit which he paid to Skipper's Creek, New Zealand, where a similar electrical scheme had been carried out by the Brush Electrical Engineering Company. We can add to this information that Crompton and Co. not long since sent out a small lighting plant for the Round Hill Syndicate in New Zealand, and it is said the lighting has been very effective. A Pelton waterwheel is used in this installation.

Taunton.—There have been some lively doings at the Taunton Town Council at the last meeting with reference to the electric lighting question, for the ground swell after the storm does not seem to have subsided. Alderman Standfast caused a scene at the previous Council meeting, the Mayor left the chair, and the meeting was broken up. At the Town Council meeting the Electric Lighting Committee reprimanded the vigorous alderman, who explained his version of the affair, and a vote of confidence in the Mayor was finally passed. The Council further presented a letter received from the Laing, Wharton, and Down Syndicate as follows: "London, August 18, 1892. Dear Sir,—The various reports which have been made by Mr. Gisbert Kapp upon the electric lighting installation in your town have come to our knowledge, and inasmuch as the electrical apparatus is all on the Thomson-Houston system supplied by us, we feel that we should have an opportunity to contradict the erroneous statements as to our system contained therein. We therefore propose to request a professional gentleman of undoubted partiality [impartiality?] to make a report which we will submit to you for presentation to your Town Council. We would therefore ask you to be good enough to let us know what names you would suggest, or, as we understand, that certain names were suggested to you by the Board of Trade, we would ask you to let us know those names, in order that we may choose a gentleman who would be acceptable to the Town Council and to the Board of Trade.—Yours faithfully, The Laing, Wharton, and Down Syndicate." The town clerk replied as follows: "Taunton, August 27, 1892. Dear Sir,—Your letter of the 16th will be laid before the Council at their meeting on the 13th Sept. My own idea of the matter is that the Council will decide not to interfere with your choice of a professional man to report upon your system of electric lighting in Taunton beyond affording the gentleman all information in their power. In reply to your question as to the names given to the Corporation by the Board of Trade at our request I must call your attention to the fact that a valuation was the principal matter upon which we required assistance; the report on the existing system was a necessary portion of the valuation. The gentlemen were Mr. Alex. P. Trotter, who did not consider valuing as part of his work, Mr. Alex. Kennedy, whose experience did not lie in valuation, and Dr. Fleming, whose fee was considered to be too high. The report of your scientist will of course receive the most careful consideration of the Council, but I do not think that they should give any opinion as to who he should be.—Yours respectfully, Thos. Meyler." The Mayor remarked, with reference to the opposition to the electric light, that it was all a question of £ s. d. The same objection was urged against the purchase of the water works, but they had made a profit of £800 a year. Councillor Adams seconded the committee's report, which, after some discussion on the Standfast incident, was adopted.

Hanley Electric Lighting.—The general supply is high tension alternating current plant, with transformers at sub-stations, and low tension distribution in the compulsory area. The following is a condensed summary of the contract with the Brush Electrical Engineering Company: Four Lancashire boilers, each 29ft. by 7ft., steam pressure, 140lb. Five vertical compound condensing engines—namely, three 200 i.h.p., and two 100 i.h.p., at a steam pressure of 120lb. Five alternators—namely, three 100 unit, and two 50 units, driven from engines by ropes. Separate vertical engine and dynamos for exciters. Separate compound engine for air and circulating pump and surface condenser. Each alternator, each exciter, and each circuit is equipped with complete switchboard. Primary mains, two lines of cast-iron socket pipes, into each of which a concentric cable is drawn from generating station on canal side to the compulsory area, together with a third line of cast-iron pipes for future requirements. Primary ring main of the same character embracing five transformer points and 10 transformers, within the compulsory area. Low tension distributing mains laid throughout the streets scheduled in the compulsory area comprises a small cast-iron trough with cast-iron lid, with two separate insulated cables embedded therein in bitumen. Total, £13,964. Street lighting within compulsory area contract includes 20 2,000 nominal candle power Brush direct current arc lamps and posts, one switchboard, two dynamos (each capable of developing 12,500 watts), two vertical compound steam engines having cylinders 6in., 10in. and 8in. stroke. Two miles 640 yards copper conductor insulated with vulcanised rubber and braided, and drawn into wrought-iron pipes, with all necessary fittings as specified. Total, £1,796. Total for general supply and street lighting, £15,760. The borough contains 1,788 acres, and is about equal to a circle having a radius of 1,650 yards. The electric lighting order compulsory area is the district between the Town Hall and the covered market, and contains 35 acres, and is about equal to a circle having a radius of 230 yards.

Abstract of Tenders Received.

Schemes utilising canal side for generating station Value of land 6s. per square yard; distance 800 yards

High tension continuous current plant with continuous current transformers to a low tension distribution in the compulsory area.

1.	The Electric Construction Corporation	£21,979

High-tension alternating current plant with transformers on customers' premises.

2.	Messrs. C. A. Parsons and Co.	19,100

High tension alternating current plant with transformers at sub stations and low tension distribution in the compulsory area.

3.	—	
4.	Messrs. J. G. Statter and Co.	18,517
5.	Messrs. J. E. H. Gordon and Co.	17,296
6.	The Laing, Wharton and Down Construction Company	15,690
7.	The Westinghouse Electric Company	14,526
8.	The Brush Electrical Engineering Company	13,964
9.	Messrs. J. D. F. Andrews and Co.	10,115

Schemes utilising land in Percy street for the generating station. This land is within the compulsory area, and is in the centre of the town, and valued at £3 per square yard. No water for condensing. Coal must be carted.

Low tension continuous current plant with accumulators.

10.	Messrs. Paterson and Cooper	20,500
11.	Messrs. Johnson and Phillips	19,350
12.	The Electric Construction Corporation	17,514
13.	Messrs. Sharp and Kent	14,150
14.	Messrs. Crompton and Co.	13,000

Low tension continuous current plant without accumulators.

15.	Messrs. Siemens Bros. and Co.	15,430
16.	Manchester Edison Swan Company	12,140
17.	Messrs. Woodhouse and Rawson	8,750

Schemes utilising land adjoining town yard for the generating station. Land valued at 6s. per square yard; distance, 400 yards. No water for condensing. Coal must be carted.

18.	Messrs. Siemens Bros. and Co. (low tension)	18,350
19.	Messrs. Johnson and Phillips (high tension)	17,550

All tenders for a total output of 400,000 watts except No. 17, which is for 300,000. The horse power varies from 450 to 800. All the low tension schemes, except No. 12, are on the three wire system. Nos. 2, 13, 14, 19 use Willans engines. Nos. 1, 3, 4, 15, 18 use horizontal engines. No. 2 uses the steam turbines coupled direct to alternators. Nos. 1 to 9 are all condensing. No. 3 withholds permission to publish. No. 9 does not include for transformers.

Street Lighting Tenders.—The tenders invited were for 20 arc lamps, distributed in the compulsory area. Some tendered for an entirely separate plant, the arc lamps being lighted and extinguished from generating station. Some tendered for alternating current lamps, controlled from a transformer station within the area. Some tendered for no separate system at all, but taking the electricity from the nearest general supply cable, and requiring the lamplighter to go round to light up or extinguish. In each of these classes there were variations, some including both arc lamps and posts, some including lamps but not posts, and others excluding both. As no fair comparison could, under these circumstances, be made, it is not desirable to publish the list of tenders.

PROVISIONAL PATENTS, 1892.

SEPTEMBER 12.

16284. **Improvements in electric call bell indicators.** William Jennings, jun., Victoria street, St. Albans, Herts.

16290. **Improved method of and means for supplying electricity to the carbon electrodes employed in the electrolysis of fused electrolytes.** Hans Heinrich Frei, 46, Lincoln's Inn fields, London.

16301. **Improvements in electrical fire and burglar alarm connections.** Homer Tong Wilson and Nathan Schwab, 77, Colmore row, Birmingham. (Complete specification.)

16315. **Improvements relating to electric telegraphs.** Frank Eustace Watkins Bowen, 6, Bream's buildings, Chancery lane, London.

SEPTEMBER 13.

16335. **Improvements in electric telephones.** Edward Marshall Harrison, Monument chambers, King William street, London. (Complete specification.)

16371. **Improvements in electric locomotives.** William Henry Soley, William Washington Perkins, James Wolstencroft, William O'Neill, and William Henry Yelland, 78, Fleet street, London. (Complete specification.)

SEPTEMBER 14.

16434. **Improvements in the construction of electric light switches, cut-outs, ceiling plates, wall-connectors, lampholders and the like.** Charles Mark Dorman and Reginald Arthur Smith, Ordsal Station Electrical Works, Salford, Manchester. (Complete specification.)

16458. **Improvements in or relating to ammeters and voltmeters.** Ernest Francis Moy and Francis Teague, 133, Strand, London.

16461. **Improvements in secondary batteries.** William Main, 6, Bream's buildings, Chancery lane, London. Date applied for under Patents Act 1883, Sec. 103, 15th February, 1892 being date of application in United States. (Complete specification.)

16469. **Improved contact fittings for movable electric lamps.** Charles Edmund Webber, 70, Chancery lane, London. (Complete specification.)

SEPTEMBER 15.

16489. **An arrangement for working an electrical rock drill or similar apparatus.** Albert Lester Taylor, 36, Dale street, Liverpool.

SEPTEMBER 16.

16545. **Improvements in and relating to dry and other galvanic batteries.** Alfred Ernest Joseph Ball, West Hoe, Plymouth.

16550. **Improvements in electric telegraphs.** Johannes Frydendahl Hjalgaard, 17, St. Ann's square, Manchester. (Hans Peter Fryd, Denmark.)

16561. **Improvements in dynamo-electric machines and motors.** Alexander William Meston, 55, Chancery lane, London. (Complete specification.)

16570. **An improved method and apparatus for electrical propulsion of vehicles.** Francis Edward Elmore, 28, Southampton buildings, Chancery lane, London.

16571. **Improvements in the connections of electric motors with the sources of electricity from which they are supplied.** Woodhouse and Rawson, United, Limited, and William Stepney Rawson, 28, Southampton buildings, Chancery lane, London.

16588. **Production of oxygen and hydrogen by electrolysis of water.** Pompeo Garuti, 24, Southampton buildings, Chancery lane, London. (Date applied for under Patents Act, 1883, Sec. 103, April 25th, being date of application in Italy.)

SEPTEMBER 17.

16614. **Improvements in and relating to advertising by means of electric light.** P. and Robert Lease Rossman, 70, High street, Southampton.

16615. **Improvements in connection with electric incandescent lamps and holders therefor.** Thomas Froggatt, 4, Moorfields, Fore street, London.

16624. **Improvements in automatic electric winding mechanism for electricity meters operated by the aid of clockwork mechanism and for clocks.** George Wilson Fairall, 56, Chancery lane, London.

16644. **Improvements in instruments for measuring electrical currents.** Siemens Bros. and Co., Limited, 28, Southampton buildings, London. (Siemens and Halske, Germany.)

16650. **Improvements in or appertaining to electric light fittings.** Frederick William Plumstead, 124, Chancery lane, London.

SPECIFICATIONS PUBLISHED.

1891.

17119. **Electrical switches.** Cheesewright.

18044. **Telephone switchboards.** Whalley.

18251. **Electricity meters.** Siemens Bros. and Co., Limited, and Baily.

18595. **Electric circuit controller.** Cleveland.

18524. **Electric conductors.** Thompson. (Hewett and another.)

19225. **Electrical indicator.** Siemens Bros. and Co., Limited, and Schlocher.

1892.

7404A. **Dynamo-electric machines, etc.** Short.

10457. **Electric resistances.** Schneider.

13549. **Dynamo-electric machines.** Andersen.

13648. **Electric railways.** Dewey.

NOTES.

Dolgelly.—The streets of Dolgelley were lighted up for the first time last week.

The Long-Distance Telephone between New York and Chicago is nearly completed.

Aldgate.—An electric light is to be placed on that old and venerated landmark, the Aldgate Pump.

Leicester.—The Leicester Gas Committee hope to deal with the electric lighting question at their next meeting.

Brooklyn.—The new Brooklyn electric power station is to have 14 Allis engines with an aggregate of 20,000 h.p.

City of London.—It will be noticed that the share list for the City of London Electric Company's fresh issue closes to-day for both town and country.

Algeria.—The town of Guelma, in Algeria, is now lighted by electricity, the installation having recently been completed by the Société Franco-Algérienne d'Electricité.

Indian Telegraphs.—Owing to the floods, it has been found impracticable to carry out the construction of the telegraph on the Chin Hills in India, and the work has been put off for a month or two.

Armature Removal.—Dynamos are now made, on the design of Stephen H. Sharpsteen, in America with tracks and travelling hangers on the dynamo frame for the easy removal of the armature for repair and inspection.

Mining Locomotives.—The Thomson Van Depoele Company are making great progress with electric mining locomotives. They have already no less than 11 of these engines at work in gold, silver, copper, iron, and coal mines.

Budapest.—The Budapest electric street railway has been such a success that we hear it is proposed to clear out the whole of the horse cars and erect a large central power station to drive all the cars in the town by electricity.

Electric Traction at Work.—In Minneapolis, where the electric trolley tramcar service is in full work, there were 26,500,000 passengers carried electrically last year, and the return for the present year is many per cent. higher still.

Southend.—Messrs. Crompton and Co. have made a report on the electrical works connected with the Southend Pier. Everything is in good order except one or two details, but they recommend a thorough inspection at the end of the season.

Ventilation of Batteries.—Captain Khotinsky states that by a special device he has been able to do away with all trouble from acid fumes in storage batteries, so that cells in ordinary use can be placed in a close cellar or other room without special ventilation.

Calcutta.—The lighting of the Harrison-road, Calcutta, has been experimentally carried out with success. The whole installation will cost, when complete, that well known sum "a lakh of rupees." The road will have 36 arc lamps of 1,200 c.p., with duplicate sets of engines and dynamos.

Guildhall.—The electric light was tested in the Press gallery in the Council-chamber at Guildhall last week, and the result of the experiment was considered highly satisfactory. In due course it will be introduced into other parts of the chamber instead of gas, and the whole of the Guildhall will eventually be so lighted.

Lightning Conductors.—We have received, in the "Specialist Series," from Messrs. Whittaker and Co "Lightning Conductors and Lightning Guards," by Prof. Oliver J. Lodge, the expansion of his well-known lectures before the Society of Arts in 1888, with appendices and illustrations, now issued in volume form.

Brown Dynamos.—M. Jean Jacques Heilmann, who is licensee for dynamos on Brown, Boveri, and Co.'s patents, has joined Messrs. Weyher et Richemond, of Pantin, to carry on the construction of these dynamos in France. M. Weyher, the managing director of this company, is also a director of the Continental Edison Company.

Statue of Liberty.—The face of the gigantic statue of Liberty in New York Harbour is thought not to be sufficiently distinct at night, and a proposal is made to put an arc lamp with a reflector to throw the light on the features of the statue. Two 100 c.p. incandescent lamps would also be placed on each of the 25 rays of the coronet.

Divers' Lamps.—Search for sunken treasure is being prosecuted by electric light in Long Island Sound, near the rock known as Hell Gate, New York. Over 100 years ago the British warship "Hussar" was sunk here with bullion to the extent of a million pounds on board, and already the spot has been found, and bones and coins have been raised by the divers to the surface.

The Junior Engineering Society.—The Council have the gratification to announce that the presidency of the society for the twelfth session has been accepted by Dr. John Hopkinson, D.Sc., F.R.S., in succession to Sir Edward J. Reed. The new session will be opened by the delivery of Dr. Hopkinson's presidential address on Friday, 4th November, at the Westminster Palace Hotel.

Mining.—The Cumberland County Council have appointed a young, but clever and experienced, teacher, Mr. James Gunson Lawn, as their lecturer on "Mining" for a twelvemonth. He is the son of the manager of the Hematite Iron and Steel Company, and has had much experience in metallurgy and physics, and will carry on classes in Barrow, Whitehaven, Maryport, and neighbouring towns.

Aberdeen University.—Mr. Charles Mitchell, of Sir William Armstrong, Mitchell, and Co., Elswick Works, has, it is understood, offered to contribute a sum of from £10,000 to £12,000 towards the extension of Aberdeen University on condition that evening science classes for artisans are established, and that professors of agriculture and engineering are appointed. It is expected that the munificent gift will be accepted.

Khotinsky Plant.—Captain Khotinsky, now settled in America with the Germania Company, has bought and redesigned the Lahmeyer machine in different sizes, and is manufacturing the Khotinsky high-voltage lamp and the Khotinsky battery, which seems to be doing well. A special set is made up for villa lighting, consisting of a rotary windmill, regulating dynamo, and storage cell, which appears to be adopted successfully.

Lineff Traction System.—We have not heard much lately of Mr. Lineff's electric closed-conduit system. It is to be feared that the telephone clause was too hard. We have heard that Mr. Lineff himself has been in America, where he fancies there will be less scruple about using a practical closed-conduit system even if the leak to earth is noticeable on a single-wire telephone. There they consider the roads to be for the use of vehicles, and not for the benefit of a telephone company.

Electric Lighting of Towns.—Thomas Reid delivered his opening lecture to the class in electrical engineering and steam in the Technical Institute, Dundee, on the 19th inst., dealing with the electric lighting of towns. The lecturer described the three-wire system, house circuits, and methods of wiring, and finally dealt with the measurement of elec-

should be as free as possible, however, from sulphate of magnesia, and in the raising of the temperature of the bath to 55deg. C. The solution takes up 30 to 75 grammes of crystallised sulphate of zinc, and 150 to 300 grammes of alkaline sulphate per litre, according to the density of current. The following are the advantages claimed: (1) The conductivity is 300 or 400 per cent. higher than that of the electrolyte of sulphate of zinc alone of the density to furnish the greatest possible conductivity; (2) a current of any strength between 10 to 140 amperes per square metre of surface can be used; (3) using condensing steam engines, a ton of zinc can be extracted from this ore for as little as three to 3½ tons of coal.

Electric Launches on the Yare.—On the waters of the Wensum and the Yare at Yarmouth is now to be seen the first specimen of electric launches which have yet been run in these parts. The "Dolce Far Niente," which is the name of the boat, is one of an electric flotilla built by Mr. K. Bowen, of Maidenhead, the largest of which, now running on the Thames, is the saloon, "Ray Mead," 65ft. in length, and registered to carry 80 passengers. The "Dolce Far Niente" is an open boat, 27ft. in length, constructed of Burmese teak, and is capable of carrying 10 passengers with the greatest comfort. A novelty in the seating arrangements is employed in the use of wicker lounge chairs. The storage cells are placed beneath the flat floor of the boat, and are capable of giving current for a run of seven hours, or a journey of 60 miles. The propeller speed is 450 revolutions per minute. The motion of the boat is delightfully easy and pleasant, and it is only likely to be the precursor of a large number of electrical boats on the smooth waters of the Norfolk Broads.

Electric Towing.—We have alluded to recent attempts to put in practice the idea of towing canal boats by electric traction, and we now notice that experiments in this direction have been made on the Saint-Maur Canal in France by a M. Levy. In these experiments, however, instead of a propeller, the method employed on the Neckar was used, of a continuous chain lying at the bottom of the canal, which is picked up and passed over a pulley on the barge. The pulley in this case was driven by an electric motor on the boat supplied with current from a trolley wire carried on posts along the bank. This seems rather a roundabout way of attaining the end, but in canal practice it is most necessary to do away with the wash of the water against the bank, which paddles, or even propellers, cannot help producing. It will be interesting to see if the chain-pulling electric barge will prove a commercial success, as it is perfectly certain a far larger proportion of heavy transport might well be given over to canal traffic if a cheap and efficient means of traction were provided.

Electric Voting.—In this age of hurry, the loss of time which occurs in all legislative assemblies over the process of voting has caused various inventors to dream of the possibility of inventing a practical electrical voting apparatus. Doubtful as it is whether the stream of members into the "aye" and "no" lobbies will be likely to cease for some time in the British Parliament, it is none the less probable that in America and in Japan—where modern ideas are prevailing—that some such an apparatus will be regularly adopted. A Japanese inventor has been working for some time on such an electrical voter with considerable success, and there is no real reason why it could not be adopted. Each member has a push button and wire locked with his own key. An electric contact releases a red ball according to contact in two directions, and when the names are noted the balls are run down into rows of 10, and counted up and sent back to their position all by electric means. A secret vote is taken by drawing down a blind and running all the balls into a receptacle, counted, and sent back without possibility of seeing who has voted.

Electric Launch.—The trial trip of an electric launch named the "Vashti" was made the other week on the Hudson river. A run of 18 miles was made in 2½ hours most satisfactorily. The boat measures 30ft., beam 6ft. 6in., with a draught of 2ft. She seats 26 persons comfortably, is driven with a 5-h.p. motor, taking only 4 h.p. usually in running, driving the propeller at 400 revolutions a minute, and making easily 8 miles an hour. There are 72 cells with a capacity of 345 watt-hours each. The motor weighs 630lb. and the cells 37½lb. each. The propeller is 20in. diameter and of 20in. pitch, developing great power with few revolutions. The switch is constructed in the form of a wheel, with the various speeds, stopping and reversing motions performed by degrees of rotation of the wheel in a very convenient manner. A peculiarity of the batteries is the substitution of zinc for lead in the negative poles, which, says Prof. William Main, electrician to the Union Electric Company, gives a higher voltage with less weight, and is a step towards the solution of light efficient traction batteries. It is expected other boats will be built on the lines of the "Vashti" for plying on the Hudson.

Cost of Electric Transmission.—A report of M. Comberousse, on behalf of the Chemical Arts Committee of the French Société d'Encouragement, upon the proposed prize of 3,000f. for the transmission of natural forces to a distance, and the proposal to award the same to M. Hillaret, contains the following observations: "A fresh increase in the cost of coal was on the point of preventing the Moutier Paper Mills from standing their ground against competitors who obtained their motive power from neighbouring waterfalls. It was this that led the owners to the adoption of electrical transmission of power, the installation for which was completed at the end of September, 1889, and put into operation without stoppage of the works. The generating dynamo, driven direct by a turbine with horizontal shaft, is put into communication with two overhead conductors, which carry the current to a motor at the works. The generator is one of 300 h.p. at 240 revolutions, and the motor represents 200 h.p. at 300 revolutions per minute. The length of the line is five kiloms. (three miles), and the maximum E.M.F was 2,850 volts, with a maximum current of 70 amperes. The annual expense of the electrical transmission is 18,750f. (£750), against 57,906f., which is the estimated cost per annum of an additional engine."

Thames Valley Towns.—Proposals are being made for lighting by electricity the various riparian towns of the Lower Thames valley. Activity at the present moment has been provoked by the action of the Brentford and Richmond Gas Companies in giving notice of an increased charge of 3d. per 1,000 cubic feet in the ensuing quarter. The Richmond Town Council have sealed a contract with an electric lighting company, and the works are already in progress. The Chiswick Local Board have applied to the Board of Trade for their sanction to a contract with Messrs. Bourne and Grant for the electric lighting of the parish, and the contractors are ready to proceed. The Twickenham Local Board at their meeting a few days ago passed a resolution of protest against the extra charge, and referred to the Lighting Committee the consideration of some other mode of lighting the town. The Heston and Isleworth Local Board, which have the largest area of any urban sanitary authority

in the kingdom, also recorded a protest against the increased imposition, and warned the Brentford Gas Company that if proceeded with the Board would consider the question of lighting the district by electricity. The Brentford Local Board have hitherto confined themselves to protest, but the feeling among the members, says the *Times* of last Monday, is so strong that they are not unlikely to follow the example of their neighbours.

Dublin.—The Dublin Corporation, after long and severe tests, have taken over the electric lighting plant. Last Friday afternoon the Electric Lighting Committee met in the works to formally take over the work from Messrs. Hammond, the sub-contractors. Mr. J. Robinson, the chairman of the Electric Lighting Committee, was present, and was accompanied by Mr. Spencer Harty, borough engineer; Mr. Beveridge, town clerk, and several others. Mr. Robert Hammond, of the firm of Hammond and Co., handed the key over to Mr. Haslam, the representative of the Electrical Engineering Company of Ireland. With an appropriate speech, Mr. Haslam in his turn handed the key to Mr. Spencer Harty, C.E., upon which the works passed into the possession of the Corporation. The lighting thereafter has been carried on by the Corporation, who have taken over the staff and leading officials. All the gas lamps have been turned off in the streets where the electric lamps are fixed. The lighting was a great success, most of the principal thoroughfares of the Irish capital being now fully and brilliantly lighted. The only private building lighted by the Corporation on the first night was the Hotel Metropole, but a considerable number are now being connected. The officials of the Hotel Metropole, from their experience of the last three weeks, speak highly of the light. Mr. Mark Ruddle will, we understand, superintend the station for the Corporation.

Finsbury College.—We have been requested to announce that the available places in the electrical laboratories of the Finsbury Technical College are already filled for Monday and Wednesday evenings of the present winter session. Applicants for attendance at the lectures only can be admitted, but there are still some vacancies in the overflow class in the laboratories on Tuesday nights. The evening ordinary lectures at the Technical College will be resumed on Oct. 3. In the advanced course on Mondays Prof. Thompson will lecture on "Dynamos and Motors," the introductory lecture on Oct. 3 being on "Magnetic Fields." The Wednesday lectures will begin with "Magnetism and Measuring Instruments." On Thursday, October 6th, Mr. G. H. Robertson, F.C.S., will commence a short "special" course of lecture on accumulators, dealing mainly with the chemical questions to which he has given so much attention. Another of the Finsbury specials is a set of four lectures by Prof. Perry, F.R.S., on gas and oil engines, which commences on November 7th, and is continued on successive Thursdays. After Christmas, Prof. Silvanus Thompson will give another short course on central stations. Throughout the winter Prof. Perry will hold a Friday night class on the applications of higher mathematics in engineering, illustrated by examples from mechanical, hydraulic, and electrical engineering. Mr. Rousseau will commence in January the course of practical instruction in the electroplating laboratory.

Belfast.—The mills, already large, of the Cogry Flax Spinning Company have recently been greatly enlarged and lighted throughout by electric light. The installation, which was one of the first in the trade, is one of the most successful in the North of Ireland, and the greater part of the work has been carried out by the mechanical staff of the mill. The dynamos are driven by the ordinary p[illegible] and there is sufficient spare water power to give a splendid light everywhere free of cost, except for lamps and repairs. The yard entrance has a 1,600-c.p. arc lamp, while throughout the building are placed incandescent lamps; and the private house of the proprietor, Mr M'Meekin, on the bank of the river near by, is also lighted from the same installation. The operatives bear strong testimony to the healthiness and comfort of the light. The *Belfast News Letter*, commenting recently on the lighting of the Cogry Mills, says: "It is, perhaps, the finest specimen we have yet witnessed of electric lighting, and we understand has so impressed all millowners and managers of large works who have seen it that experiments of a similar nature are pending. Those who have tried it before and relinquished the idea are, we understand, again in the field, especially companies whose manufactories occupy suburban situations. Mr. M'Meekin speaks highly of its application in the linen trade, and asserts in the most unqualified manner that its introduction in all large concerns of the kind is a matter of only a very short time."

Pure Platinum.—The quantity of platinum extracted in Russia during 1891 was 258 poude, a poud being 35lb., this makes a total of about four tons. Platinum is extracted by private companies, which are obliged to pay a royalty of eight pouds of raw platinum containing 80·59 per cent. pure metal. As the poud is worth 5,000 roubles, the total quantity extracted in 1891 amounted to a million and a quarter roubles. These figures give some idea of the costliness of the present methods of extraction. A simple and less costly method than that generally employed has been published by M. Finkener, using the successive crystallisations of the double chlorides of platinum and sodium. To the platinum of commerce dissolved in hydrochloric acid is added the calculated quantity of chloride of sodium to give, after concentration and cooling, crystals of double chloride. The water is poured off and the crystals washed in a concentrated solution of chloride of sodium, and redissolved in a 1 per cent. solution of carbonate of soda. Cooled again, the solution deposits crystals of pure double chloride, which is dried at 120deg. and reduced in a current of hydrogen. There are very few absolutely pure specimens of platinum. The commercial metal has many impurities, such as small quantities of iridium, ruthenium, rhodium, palladium, iron, copper, silver, etc. When it is remembered how greatly small impurities affect the properties of almost every metal, the simple process of M. Finkener is likely to facilitate researches on pure platinum.

Accumulator for Traction.—Mr. Weyde-Elsner describes (says the Institute of Civil Engineers' *Abstracts*) the various properties which a good type of cell ought to possess, and remarks that such cells are subjected to very rough usage in traction work. They should be able to discharge very large currents, and should be as light as possible. The new cells differ in many respects from those most in use in this country. Long thin channels of celluloid are used as supporting frames. The cross-section of the channels is approximately one-third of a circle. The active material consists of peroxide of lead, and it is pressed into solid short cylinders as hard as the carbon for arc lamps; each cylinder has a hole along its axis, and they are all "formed" before being placed in position. They are then coated with a special conducting cement, and laid at a short distance apart inside two channel-shaped strips of sheet lead, each of which is provided with a wide lug at one end. Each set of five cylinders, with the lead conducting strips, are then placed inside a pair of celluloid channels. About eight of these complete sets are then mounted vertically, and held together by

bands of celluloid. Celluloid tubes also pass through holes at each end of the celluloid channels. The whole is held firmly together by wooden wedges. All the lead strips are then soldered on to one common bar, and the compounds form either the positive or negative plate in a cell. It is claimed that the construction is solid, and that only the thin lead conductors on the positive plates deteriorate, and can easily be renewed.

Telephones in India.—The Indian Telegraph Department have made great strides in the past year in the establishment of telephone exchanges in our large inland towns, says the *Indian Engineer*, and they hope still further to extend the benefits of telephony very soon. The public, so far, have not realised what improvements have lately been made in telephones. The older instruments were constantly getting out of order, and those who paid for their use soon grew weary of constantly calling upon the department to put them in working order. Now, however, there are scarcely any complaints where exchanges are at work. In order to still further popularise the use of the telephone, Mr. Brooke, Director-General of Telegraphs, has recently obtained from England a large number of instruments of the British Post Office pattern. These are simple in construction, absolutely reliable, and reproduce words spoken into them with a distinctness which is little short of marvellous. They are as much in advance of the original instruments used in India as the Magazine rifle is of the Snider. The "Berliner" telephone made in Hanover, is also being tried experimentally. This is a most ingenious instrument, the words being heard even when the earpiece is held some inches away. Its mechanism is somewhat delicate, but the Berliner must have a great future before it. In India the telephone should be largely employed, not merely in commercial centres, but in all towns and cantonments for linking up police posts, courts, treasuries, public offices, and the like with each other, and, in some cases, with the houses of civil and military officials.

Nottingham Technical Schools.—The new technical schools added to the Nottingham University College are approaching completion, and will be opened in about a month. The master and warden of the Drapers' Company will be at the opening, assisted, amongst others, by Prof. Perry, who will give an address, and it is hoped for the presence of Sir Albert Rollit, president of the Chamber of Commerce. Classes are already in process of organisation, and there are now about 50 day students and about 1,000 evening pupils actively pursuing their studies in the various departments, while in that devoted to electrical science they are enabled to obtain practical training by assisting in the wiring and erection of the installation for lighting the whole of the new buildings by electricity. Messrs. Manlove and Alliott, of Bloomsgrove Works, Nottingham, have erected in the new building an experimental engine at a cost of upwards of £500. The engine will drive the machinery in the workshops in ordinary working, and is adapted to be arranged in a variety of ways for experimental purposes. This firm has generously contributed 200 guineas of the cost of this fine machinery. The Technical Education Committee have received the hearty co-operation of various engineering firms in the country, the result being that about £4,000 worth of machinery is being put in at a cost of £2,400. This is in addition to the fittings in the old temporary shops, all the shop tools and machinery being utilised in the new shops. The senior electrical students are actively engaged under Prof. Robinson and a foreman from the Brush Company on the electric installation, and a high-speed engine, with the requisite dynamos, are being placed in position. These were supplied by the Brush Company, who have also made a liberal allowance off the cost for the purpose of promoting the cause of technical education, only charging £600 for a plant which is estimated to be worth £1,000. It is intended that the lighting shall be in the hands of the students, who, under the direction of the professor of engineering and staff, will take entire charge of the plant, and keep it in working order. In the lecture-room the furniture and fittings will be on the most approved principles, and this remark especially applies to the blackboards, which are constructed in conformity with the model of those at Finsbury Technical College, which have an ingenious mechanical arrangement for raising and lowering them to suit the convenience of the lecturer. These boards were designed by the late Prof. Thomson, brother of Lord Kelvin. The entire construction of the building has been carried out under the superintendence of Prof. Robinson, who has given great care and thought to the arrangement of the technical details.

Lamp Vacua.—M. C. Boccali has investigated this question. His method is to take a petroleum bath kept at a temperature of 68deg. F., and noting the current required to raise the temperature of the filament to 122deg. F. For this purpose an arrangement of Wheatstone bridge and galvanometer is used, which is described in detail. The bath is first heated to 122deg. F., and the resistance, R, of the filament is taken; this must be obtained with a current of about 0·3 milliampere, so as not to heat the bath. The bath is then cooled to 68deg., and the resistance of the filament remaining the same, the current, C, is noted. This value C represents the current which is required to heat the filament to 122deg. F., while the surrounding temperature is 68deg. The resistence, *r*, is that of the filament at 68deg., and is obtained with a current of 0·3 milliampere.

Lamp No.	Ohms. *r*.	Ohms. R.	Milliamps. C.	Milliwatt. R × C.	*a*.
1	182·9	178·0	6·64	7·85	186
2	169·8	164·8	7·24	8·64	183
3	188·6	183·5	7·14	9·52	176·5
4	161·7	157·4	7·81	9·60	182·5
5	159·4	155·6	9·00	12·60	180·0
6	165·8	161·2	9·20	13·61	173 0
7	172·0	167·4	9·40	14·80	168·5

The table gives the results of experiments made upon seven lamps of 65-66 volts and 16 c.p. of the same type and by the same makers. It appears, therefore, from these tests that No. 1 lamp is very much the best, as it required only 7·85 milliwatts to heat it to 122deg., while No. 7 required about double. The difference in resistance of the filaments is not 9 per cent., and is not enough to account for the figures R × C. The results are therefore caused by differences in the vacuums of the lamps. A check test was made by a different method. In order to obtain equality of temperature inside and outside the lamp, a certain time is necessary, and the better the vacuum the longer the time needed. The exact time is difficult to measure, but for a series of lamps figures can be obtained which depend upon the time. In place of the lamp, a resistance equal to its resistance at 122deg. is inserted, a current, C, is passed through, and the throw of the galvanometer made equal to, say, two hundred scale divisions. The lamp is now inserted, and the throw observed; this will always be less than 200, and will vary according to the perfection of the vacuum. In this way the figures in column *a* were obtained; these all agree with the other results, except that for lamp No. 3, and the discrepancy in this case is due to the fact that the filament was much out of the centre, and near to the glass globe at one point.—*Abstracts* I.C.E.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

II.—MOTIVE POWER.

(Continued from page 316.)

COAL AS FUEL.

It is the sun that, through its rays of heat energy, causes trees, plants, and other vegetable and organic matter to spring out of the earth, grow, flourish for their allotted time, afterwards to gradually decay and die off; decomposition then sets in, and the matter sinks into the earth whence it came. The unceasing action of the sun's energy brings forth a fresh supply of living vegetable matter to take the place of the dead; this in its turn decays and dies after its season, and so layer after layer gets buried deep in the earth, each layer passing through successive chemical changes, due partly to the internal heat of the earth, etc. In this way coal is formed. The existing coalfields have been formed from decomposed plants and herbaceous matter that flourished as great primeval forests in ages so remote that the lapse of time may be counted as millions of years at this early period of the earth's division into land and water. We have every reason to imagine the soil entirely covered with a dense and luxuriant growth of ferns, reeds, grass, etc., of a gigantic size, the soil being partly submerged in water, thus forming huge swamps. This extraordinary carboniferous age is attributed to the humidity of the soil and the warm or possible tropical climate that was likely to exist at that time in places which are now temperate or frigid. No human being or animal could have lived in this vegetable world in the midst of vapours evolved by the decomposing matter. The only animal objects that inhabited the earth being, as far as we can tell, curious forms of reptile, fish, and such like imperfect organisms.

It is easy to see how the heat energy of the sun is transferred into coal, in the form of latent or stored heat, which ages after becomes liberated upon the coal being burnt. This provides one of the most beautiful examples there is of the conservation of energy. Living plants and vegetable matter derive their food from the atmosphere, absorbing the carbonic acid gas, or carbon dioxide (CO_2), that is present. The sun expends part of its heat rays in decomposing this gas—that is, its warmth acting on the delicate leaf cells, has the effect of splitting up the carbon dioxide into its component parts, namely, carbon and oxygen—so that every molecule of CO_2 is split up into one atom of carbon and two atoms of oxygen. Now, to tear away the oxygen atoms from the carbon atom, or, in chemical parlance, to overcome their chemical affinity, requires a great amount of energy, and since energy is a form of heat, hence a great deal of heat must be expended by the sun to do this. The oxygen atoms being set free, the carbon atoms remain behind to form the structure of the plant; this is why all woody matter, etc., consists greatly of carbon. The first opportunity that occurs, the carbon atoms join on to oxygen atoms, so as to regain their condition as CO_2. When oxygen and carbon combine they always evolve great heat, so when coal or any other carboniferous matter is burnt in the atmosphere, the carbon seizes hold of the oxygen in the atmosphere, and these combining give out such heat that the carbon atom is made incandescent, or white hot; this action being continuous, produces what we call flame. The flame of a candle is a hollow cone, the cone being formed by a thin film or envelope of glowing carbon. When the air supply becomes scant, the candle grows dim, simply because there is not sufficient oxygen present to combine with the carbon, consequently the latter only get partially consumed, and smoke is given off instead of a glow vapour. From this it can be understood that the heat given out by burning coal is exactly equivalent in amount to the heat that was expended in producing the coal. Returning, however, to the formation of coal, the first result of the decomposition of the vegetable matter is a produce called peat, a dark brown solid soil, the richer kinds being almost black. This peaty soil is found extensively in Ireland, in the swamps, marshes, and bogs with which that country abounds. The depth of the soil varies from a couple of feet to 50ft; the top layers are usually of a light reddish-brown colour, deeper down the hue changes to a dark brown, and still deeper it is almost black. As the depth increases, the soil, in addition, gets heavier and more solid, so that the surface peat is light and fibrous, and the black peat heavy and compact. It is used by the peasantry for fuel, after being first well dried. When thoroughly compressed and dried, it gives an evaporative power when burnt equal to one half that given by ordinary coal, comparing equal weights. It is a great deal used as boiler fuel in districts where it is obtained in quantity. The second stage produces "bituminous or common coal"; this after a while becomes harder and harder until the third stage is reached, when "anthracite coal" is produced. Any further lapse of time turns this kind of coal, which is the best, into fossilised coal, which is so hard that it is almost impossible to get it to burn. All organic matter contains carbon and hydrogen, and nearly all oxygen in addition, and all vegetable matter consists of carbon, hydrogen, and oxygen in various proportions, and having various chemical combinations according to the nature and structure of the plant, a few impurities, such as minerals, being usually present. Herbaceous matter contains more than 50 per cent. of carbon, about 5 per cent. of hydrogen, and more than 40 per cent. of oxygen. As it undergoes changes and decomposition, the oxygen decreases, whilst the carbon increases, and the more it progresses towards being formed into coal, so the oxygen decreases and the carbon increases, the hydrogen remaining fairly constant, except when bituminous coal changes into anthracite, and then it decreases.

The following table gives a rough idea of the composition of the coal-forming matter in four stages:

Element.	Wood.	Peat.	Bituminous.	Anthracite.
Carbon	52	60	75	93
Hydrogen	5	5	5	4
Oxygen ...	43	35	20	3

so that the best coal is composed of nearly all carbon.

1lb. of hydrogen completely burnt, evolves 62,032 heat units.
1lb. of carbon „ „ „ 14,500 „

One heat unit (British) is the amount of heat required to raise 1lb. of water from 60deg. F. to 61deg. F. = 1deg. F., and in mechanical energy it is equivalent to 772·5 foot-pounds. 1lb. of coal gives out about the same heat energy as 1lb. of carbon, hence 1lb. of coal when burnt will produce $772·5 \times 14{,}500 = 11{,}201{,}050$ foot-pounds of energy.

Let 1lb. of good anthracite coal, when burnt thoroughly, give out heat energy equal to, say, 11,000,000 foot-pounds—that is to say, an amount of energy sufficient to raise a weight of 11,000,000lb. a vertical distance of 1ft. One horse-power signifies 33,000 foot-pounds of work done in the space of one minute of time. If the coal be burnt in the space of one hour, this gives $\frac{11{,}000{,}000}{60}$ foot-pounds per minute, and dividing this by 33,000, will give $\frac{11{,}000{,}000}{60 \times 33000} =$ 20·2 h.p., so that burning coal at the rate of 1lb. per hour gives out heat energy equivalent to above 20 h.p., this being the total or theoretical energy given out. A great amount of this energy is wasted, and, roughly, only 50 per cent., or one half of it, can be said to be utilised. This useful half is employed to evaporate the water in a boiler, and the number of pounds of water that are converted into steam determines what is called the "evaporative power" of the coal, the steam being at an atmospheric pressure and at a temperature of 100deg. C. If the whole of the heat energy of 1lb. of coal were turned to account, it would evaporate about 15lb. of water; but since 50 per cent. of this is lost, therefore only 7·5lb. of water can be turned into steam, so that the efficiency of a boiler may be put down at 50 per cent.

The heat given out by burning fuel is called the "total or theoretical heat of combustion," and that portion which is utilised is called the "available or practical heat of combustion." The amount of heat evolved by coal depends a great deal on its quality and chemical composition. Carbon

and hydrogen are the valuable elements in fuel, and the percentage of these vary considerably. It need scarcely be said that the choice of coal for a boiler is most important and weighty, and becomes more so as the size and number of boilers increase. The coal bill is always the heaviest item in the working expenses of a central station, so it is natural that every buyer should try to obtain the coal that will give a maximum amount of heat for a minimum cost, taking care that the coal chosen is of a nature to suit the particular type of boiler employed.

The following table gives reliable and most careful analyses of the chief kinds of coal in Great Britain (compiled by Prof. W. Foster).

PERCENTAGE OF COMPOSITION.

Description of fuel.	Hydrogen.	Carbon.	Moisture	Ash.	Heat units per lb. of fuel
Welsh anthracite	3·5	89 17	1·78	2·12	15 017
Durham coal caking	5 3	84·31	1·14	2·42	15,221
Yorkshire coal ...	4·93	84 1	2 2	1 2	14,875
English cannel coal	5 02	81·46	2·07	5 8	14 571
Scotch cannel coal	6·18	75 42	4·0	2 24	15,750

Small quantities of nitrogen, sulphur, and oxygen are also present.

(To be continued.)

ON THE MANUFACTURE OF INCANDESCENT ELECTRIC LAMPS.

BY FREDERICK GRAHAM ANSELL, F.C.S.

(Continued from page 312.)

To flash in benzene, then, an air-tight vessel must be provided in place of H, somewhat like an ordinary air pump receiver, the electric wires must pass through the base plates, and a tube must be provided for exhausting the air and for letting in the benzene vapour. All mechanical arrangements should be avoided as far as possible, mercury pumps being much better, and, generally speaking, the better the vacuum the better the result of the flashing.

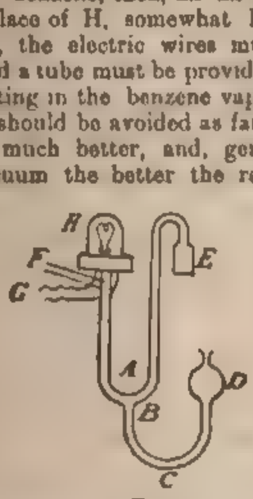

FIG. 5.

When the air is all out, the benzene vapour may be let in by lowering the mercury in a U-tube placed between the air pump receiver and the vessel containing the benzene, as shown in Fig 5, where E contains the benzene, H is the receiver with the filament inside, G the electric wires, A the U-tube, with a piece of indiarubber tube, C, joined on at B, and D is a funnel. F leads to the air pump. To start, E must be nearly full of benzene, and D low down, then pumping started, and when the vacuum is good the filament flashed. When the flashing is done, D must first be raised, so that mercury is well up the U-tube, A, and then, the air being let in slowly, the mercury will rise about 30in. in the tube leading to E. The next filament can now be mounted ready for flashing, H exhausted, and then D lowered for a minute or so, when H will soon fill with benzene; D can then be raised, the filament flashed, and the air let in very gently so as not to cause the mercury to rush over into E. It will now be seen that the U-tube, etc., acts as a virtual tap.

There are several other hydrocarbons which might be used for flashing, such as chloroform, toluol, cyniol, etc., but benzene gives the best results. A certain amount of practice will be found necessary before this rather delicate operation of flashing can be thoroughly well performed, and it is always advisable to keep the connecting joints between the platinum leading-in wires and the carbon filament as small as possible, otherwise they will not get hot enough to deposit carbon from the vapour of benzene or any other hydrocarbon.

We may now fairly suppose that our filament is complete, and can be given to the glassblower with instructions to join the glass upon which it is mounted as neatly as possible into the globe of the lamp. This operation will present no difficulty to a good glassblower. A small tube, A B, Fig. 2, will be required at the pointed end of the globe, to enable the lamp to be attached to the air pump. No indiarubber or mechanical joint will do for this purpose. The lamp tube must be blown on to the tube of the air pump, as shown in Fig. 6, which is a section of Sprengel's air pump—the best for our purpose. To put this pump in action, mercury is poured gently into the funnel, A, when by force of gravitation it flows up the other side of the U-tube to the horizontal tube, B, which is melted into a larger tube, C, in communication with a drying vessel, D, and the branches, E, on to which the lamps, F, are fused. The horizontal tube, B, is closed at the end, but has some small openings in its under side exactly over the tubes G, of which there may be any number—not less than, say, six. The mercury should be so fed into the funnel, A, that it shall fall through the openings in B in small globules down the tubes G, which must

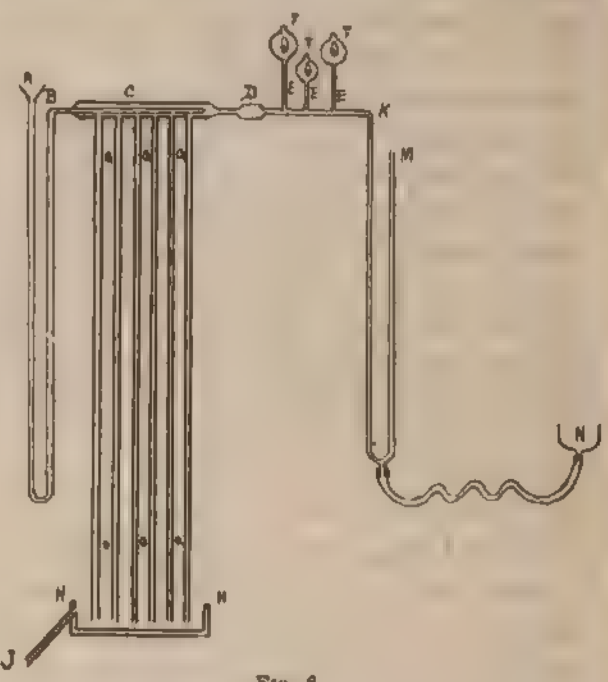

FIG. 6.

not be less than 36in. long, or of larger bore, then the globules of mercury will fall down the tubes G, and in doing so will take with them the air from the large tube, C, that from the tube E, and also from the lamps, F, etc. The bottom of each tube G must dip well below the surface of the mercury in the little trough, H, which must be provided with an overflow pipe, as shown at J, and must also allow the air to escape freely as it comes down the tubes G. The mercury must be caught at J, and so can be used over and over again. At first the mercury should be poured very slowly into A, because the large quantity of air between the drops of mercury as they fall into the tubes G causes them to descend slowly, and the operator will soon observe that at starting the pump works almost without noise, but as the vacuum begins to form a solid column of mercury begins to rise in G, and the globules falling on this will strike harder and harder. This sound, together with the height of the columns of mercury in the tubes G will afford an indication of how the exhaustion is

proceeding. When the columns cease to rise the pump should be stopped for a few minutes, and the height of the columns carefully noted in order to ascertain that there is no leak anywhere. The height of these columns must always be at least as high as the barometer at the time of the exhaustion, but, generally speaking, it will be higher than the barometer, because these pumps are exceedingly efficient. When no alteration in the sound of the falling drops of mercury has been observed for some considerable time, a small current of electricity, just enough to make the filament red, should be turned on, and generally this will stop the sound of the falling drops for a few minutes. When the sound has returned, a little more current may be turned on, and so on until a further addition of current makes no difference to the sound. In this way, the lamp should be raised somewhat above its normal brightness and the pump kept going all the time for about 20 or 30 minutes. The vacuum should then be sufficiently perfect, and the lamp may be disconnected by means of a hand blow pipe from the pump, but the filament should be kept fully incandescent during this little operation by the electricity. The current may then be turned off and the lamp will be complete. In taking a lamp from the pump, the operator must be very careful to heat the small connecting tube only just enough to enable him to draw away the lamp, as if the glass is made too soft the pressure of the atmosphere will be certain to force a hole through the glass, and then the lamp will be destroyed and the vacuum in the pump lost, but if the tube is only just softened by the blow-pipe flame all round, then there is no fear of this calamity with its lamentable waste of time. The author has generally observed that these pumps, although all made alike, vary a good deal in the length of time they take to get a good vacuum, and he would draw attention, in passing, to the interesting, though unimportant, fact that the drops of mercury in falling through the tubes G give rather pretty blue streamers of frictional electricity when the vacuum reaches and remains at a certain stage, but they disappear as the vacuum becomes really good. Of course, they can only be seen in the dark. Those who use these ingenious air pumps will also observe, to their sorrow, that the falling drops in the tubes G have a most unpleasant way of breaking the tubes. The only remedy is to seal the tube above the break, and then to replace it by a new one on the first convenient opportunity. In order to escape the poisonous vapour given off by the mercury, care should be taken in designing the pumps, etc., that as far as possible all the mercury should be kept in tubes and covered receptacles, the air escaping from the little trough, H, being led through a pipe into the outer air away from the operating-room, which must be kept well ventilated. Too much attention cannot be paid to this important matter, as it is a real danger, the author having known several serious cases of mercury poisoning through its neglect.

Referring to Fig. 6, which is arranged as simply as possible to show the principle of the pump, it would be a good plan to dispense with the funnel, A, to put a somewhat capacious covered vessel under J, and then to connect them by means of an iron plunger force pump. In the tube J and all similar places great care should be taken that the mercury does not fall, but runs down an incline. If this precaution is neglected, the mercury will in the course of a short time break itself up into an immense number of small globules, which adhere closely together in a soft pasty mass, and will be sure to block up any passage they may be in. Iron is the only metal suitable for use in contact with the mercury, as any other would be attacked and dissolved by it, and dirty or impure mercury would give trouble in the pump and elsewhere.

(*To be continued.*)

CARBONS.*

BY H. O. FISK.

It was suggested at one of our committee meetings that I should prepare a paper for this convention on carbon testing, but the time was too short to carry out a series of experiments as at first spoken of, so, instead, I have prepared a short description of the process of manufacture of carbon points as conducted at the factory in Peterborough.

Twenty five per cent. of gas coke mixed with 75 per cent. of petroleum coke is said to make a good carbon for low-tension work. Another variety of this material is obtained from the oil regions, commonly known as petroleum coke. This is a by product of the oil stills, and is the only kind used to any great extent in the manufacture of carbon points for the electrical industry. It is of primary importance that the coke, and, in fact, all the ingredients used, be absolutely free from impurities. The other constituent of our carbon is pitch. This is made from coal tar, which is a by product of the gas retorts. It may also be obtained from blast furnaces, but this kind is more or less contaminated with iron, and therefore is unfit for this class of work. Pitch for this particular purpose is difficult to obtain, as the makers do not care to expose their stills to the high temperature necessary to drive out all the oil and reduce it to the proper specific gravity, and, as the men in the factory say, "it is more or less wet."

The first step in the process of manufacture is that of crushing the coke. This is accomplished by means of a machine somewhat in appearance like a mammoth coffee mill. The coke comes from this crushed to about the size of coarse gravel, it is then automatically elevated to a large bin in the upper part of the factory, and from there it is conveyed to a large iron hopper situated directly over the calcining retorts. Into these the granulated coke is conducted by means of spouts with gates arranged to control the flow of material into the several aforementioned retorts. They are then sealed up, thereby preventing combustion, with the exception of a few vents to allow of the escape of gas arising from the heating of the coke to a state of incandescence, which point is reached in from 24 to 48 hours after firing. After this, if the coke is not pure it will be found to have caked, necessitating in some cases the use of bars to break it up sufficiently to allow of its being drawn from the retorts. If pure it will appear crisp and dry and to have suffered a loss in weight of about 30 per cent. After the retorts have been drawn sufficiently long to allow the cooling, their contents are elevated to the milling department and run through a set of French burr stones encased in iron, very similar to the grist mill chop stones, then through a silk bolter, separating the coarse from the fine, the former returning to the milling-machine, the latter being conveyed to bins with suitably arranged spouts over scales, from which it may be drawn and weighed as required by the mixing department. We will leave the coke here for the present and return to the other ingredient—namely, the pitch. This is dense, hard, solid, very brittle and dry, and in appearance somewhat resembling gutta percha. This material, when it reaches the factory, is encased in casks holding about 600lb. each. It is then broken up by the men into a convenient size for handling, and subjected to a granulating process similar to that of the coke, finally, we find it at a spout close beside the one from which the coke can be drawn.

We have now followed the two principal ingredients through the various processes which were necessary to prepare them for the mixing room. The other ingredients, if any, we shall not be able to elaborate upon until we have reached a more confidential relationship with the carbon makers. However, upon the manipulation of the materials at this stage I am told the success of the future carbon greatly depends, in fact, the great secret lies in the mixing. We can better understand the skill and care required to properly amalgamate the mixture when we learn that each particle or grain of coke must have its individual coating of pitch, and it may be interesting to learn that this coke is ground so fine that a grain magnified a thousand times would only appear the size of a shot. To obtain these results, the materials are carefully proportioned by weight and placed in a mixing barrel. This is a rotating cast iron cylinder within which, in the same direction, revolves an independent shaft twice as fast as the cylinder, to which are attached arms so arranged that every part of the barrel is covered or swept in each

* Abstract of paper read before the Canadian Electrical Association.

revolution. This is attached to a furnace in such a way that the flues follow the whole circumference of this barrel, maintaining a uniform temperature of about 300deg F., which is necessary to bring the pitch to a state sufficiently plastic for amalgamation. Thirty minutes is the time required for each batch, which would make about 1,600 carbons. From this machine it is taken to the cooling-room and spread out for 10 or 12 hours to cool. Here the mixture solidifies to such an extent that it becomes necessary to pulverise it again to perfect it for the moulds. This end is attained by means of a mill, the pulverising feature of which is two discs 30in. in diameter, with corrugated face plates revolving in opposite directions at the rate of 1,500 revolutions per minute (about one one-hundredth of an inch apart). From this it is once more passed through a bolting machine, and then, finding its way down gravity tubes to a bin on the floor below (which is the moulding-room), it is carefully weighed out by the workmen on peculiar little scales with clock-like dials, in quantities just sufficient to fill each mould as it comes hot from the oven.

The mould having been previously lubricated with some heavy oils, and now ready for its charge, which the operator places in it and works evenly over the whole surface with a spatula, to ensure uniformity of density, the cover or top half is placed in position, and the mould and its contents pass for a few moments into an oven, the temperature of which is about 300deg. F. As soon as the mixture has become quite adhesive, the mould is placed in the hydraulic press and subjected to a pressure of several hundred tons. The mould is now removed and opened, and we have a corrugated card containing 16 or 18 carbons, each one being joined to its neighbour by a fin which is inevitably formed when subjected to the enormous pressure before mentioned. These cards are placed on plates which are fitted to receive them perfectly. These plates with their contents are piled up, and weights placed thereon to prevent warping. When cool they are broken apart, gauged for size, culled, and the fin scraped off. They are then laid in the furnace for baking. This furnace is rectangular in shape, 34 by 11, 4ft. deep, and made of fire-brick, and is similar to a large vat set about two-thirds below the surface of the earth. Over this, when filled, is placed a dome-shaped cover, sufficiently high above the sand and tile which covers the carbon to allow of a free passage of the flames, and which is continued by flues back through the sides and also underneath, thus completely enveloping the body of the furnace in flames. The carbons are carefully placed in the furnace and separated from each other with washed sand, which is brought from the shores of Lake Ontario. Some days are required to completely load a furnace, as each section will hold about 75,000 carbons.

The cover having been placed in position and sealed with fireclay, the fire is now started, crude oil being the fuel used, as well as in the case of the retorts and moulders' oven. This fire is continued moderately for 48 hours to allow of the gas escaping without blistering the carbon; it is then forced to its utmost for from 48 to 60 hours longer, then shut off, and the whole allowed to cool for 48 hours before uncovering. The top, which is mounted on wheels, is then rolled off and a few carbons taken from various parts of the furnace and tested by a Wheatstone bridge and galvanometer for resistance, as this at once determines if the baking has been carried sufficiently far. If the measurements of all the samples exceed four-tenths of an ohm the furnace is recovered and fired for some hours longer, but this very rarely has to be done. The writer recently tested samples from the north and south ends and centre of a furnace, and they measured 23, 22, and 24 one hundredths of an ohm respectively. Some difficulty was at first experienced in attaching carbons to the bridge, for the resistance of this substance varies considerably with the pressure of contact, and the same carbon measured at different times would often vary several one hundredths of an ohm. But an instrument was designed by the writer which obviated to a great extent, if not wholly, this trouble. The pressure brought to bear on the sample undergoing test by this instrument is determined by small weights suspended from levers attached to holders so arranged that exactly the same pressure and contact is formed on different samples of the same size. If the resistance of the samples, as before mentioned, shows that the contents of the furnace have been sufficiently baked, it is unloaded, the hot carbon being handled with forks.

When cold they are sorted, the first and seconds being easily determined by rolling on level steel plates. After this inspection they are ready for the plating-room, where they receive their copper coat by being hung in leaden vats containing a saturated solution of sulphate of copper. These vats, of which there are several dozen, are connected in series with a 20-ampere constant-current dynamo. Twenty minutes to half an hour is the time required to complete this plating process. They are then washed in hot and cold water and placed on racks to dry, after which they go to the packing department to be rolled in paper and boxed for shipment.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE II.

(Concluded from page 315.)

We must consider the fact that, in working this way, we are conveying our power from our central station to the sub-stations by means of high-pressure electricity; and we are committing ourselves to the statement that high-pressure electricity is the most economical means by which we can transmit power from one place to another. There are several ways in which we can carry power from a central station to different parts of a town. We can do it by passing air compressed at a central station through pipes to the different sub-stations, there using it in engines, which may be ordinary steam engines, to drive our dynamos. Or, we may do it by means of water which is kept under pressure by pumping it into hydraulic accumulators at a central station. From this central station the high-pressure water may similarly be led through mains in the town, and be utilised in water motors for driving the electrical machinery at the sub-stations. These are two ways, besides the electrical way, in which power may be given to the sub-stations from the central source, and we have to consider which of these three is the most economical. The compressed-air method is being largely used at Birmingham. It is also being used for electric lighting in Paris on the Popp system. I do not say that at the present moment the results have been altogether economical, but I do say that the system of transmitting our power to sub-stations by compressed air deserves far more serious attention than has been generally accorded to it. I have heard people who were in ignorance of the methods which can be used for supplying compressed air, or who have only had experience with very defective apparatus for this purpose, speak of the mere 20 or 30 per cent. efficiency obtainable; this is utterly erroneous. The efficiency you can get is very good indeed, and the difficulty lies not so much in that as in the large space taken up in the streets by the pipes to carry the compressed air. The same remarks apply to water power. High pressure water is now being distributed through London from the large central stations of the Hydraulic Power Company. That water is used chiefly for working lifts or elevators; it may be used for other purposes. Here, also, the economy is good. Here, again, the difficulty is a 6in. main which is being used. The total power which can be supplied through such a size of main at the pressure of 700lb. is something like 100 h.p. So that when we come to transmit large powers, the space which would be occupied by the mains would be too large to allow of the system being really practicable in most cases. There might be cases in outlying towns—in parts of London even—where the roadway is not filled up with pipes, where it might be desirable to introduce compressed air or hydraulic power. But probably these cases are very few; and certainly in busy parts, like the city of London, or the greater number of the streets in London, it would

* Cantor Lectures delivered before the Society of Arts.

be too expensive to proceed in this way. So that, in all probability, the high-pressure electrical system is the best for supplying sub-stations; but I beg electrical engineers not to cast aside, as utterly useless, the other means of supplying power from central stations, which may, in some cases, be useful. There is still another way, and that is by the distribution of gas; either the ordinary illuminating gas, or gas specially prepared for heating purposes. Of the latter kind, the best known is the Dowson gas, which can be produced extremely economically—at about 10d. per 1,000ft. The question is, simply, Is it ever economical to introduce gas engines in sub-stations, instead of generating power by steam engines? I have no hesitation in saying that it is in very many cases economical. Gas engines have increased in use in the last few years; the sizes of gas engines have also been increased. Hitherto gas engines have not been made very large, solely because the purposes for which they have been required have generally been those requiring small amounts of power; and people have been doubtful of their applicability to purposes requiring large power. The largest gas engines indicate 170 b.p. with ordinary gas, or about 160 with Dowson gas. Such gas engines are in use in London, and can be seen at work at any time; there are also 98-h.p. engines working at Portsmouth for generating electricity. neers, and that in designing central stations in future, this plan will not be lost sight of.

I will now conclude with referring shortly to some of the systems adopted for laying conductors underground, and will describe to you an ingenious automatic safety device of Mr. Ferranti's, which is appropriate to this lecture. I need hardly take up time with describing different kinds of cable used. We have cables insulated with vulcanised indiarubber, okonite, various bituminous compounds, and air. Some people have used lead covered cables, while in other cases the conductors are left bare. I pointed out a few years ago some serious defects which had occurred in the lead-covered cables employed in Berlin and Rome, due to faults in the manufacture, and want of care in laying. Great improvements have, however, been made since then. I also described, at the meeting of the British Association in Manchester, in 1887, a system of mains which is exceedingly simple. I use cast-iron pipes, and run bare copper tubes through them. The copper tubes, which are supported on porcelain insulators, Fig. 1, may be first used as the conductors alone, and when the demand increases, bare wires can be drawn through the tubes. In the figure, which is more or less diagrammatic, the method of making a house connection is shown, the tubes being tapped into the side of the pipe, through which

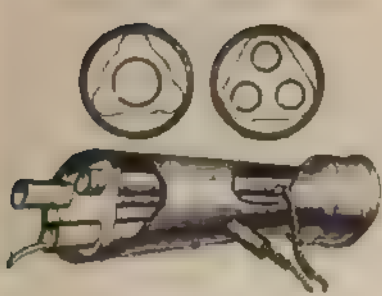

Fig. 1.

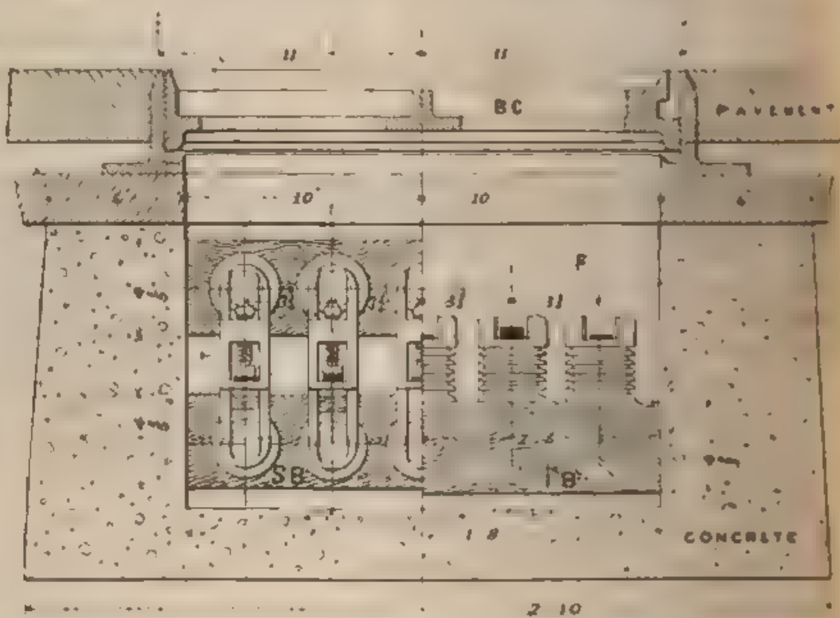

Fig. 2.

The floor space taken up is 14 square feet, therefore the space is not large compared with steam. It would be perfectly easy to make larger ones if they were wanted, but I believe that for such sub-stations as those in which they would be likely to be used, 170 h.p. is as large a size as it would be desirable to introduce, and we should, therefore, be simply using gas engines on the market at the present moment. It is asserted that only 16 cubic feet of gas per horse-power hour indicated is used, and, therefore, even allowing a slight margin for the sanguineness of the manufacturers, we should reduce the cost of power to a very moderate figure, especially in places where gas is very cheap. When we look at this question of using gas engines in its bearing on the load curves I have been speaking of, you will see the enormous gain gas engines could effect. With gas engines, you do not require to be firing up boilers long beforehand for a few hours' work; your gas is always ready, and you can start at the time you have to supply power, without having gone to any waste beforehand in getting your plant into working order, as with steam plant. A large proportion of the 9lb. or 10lb. or 15lb. of coal to the electrical unit needed with steam plant is consumed in heating up the boilers preparatory to starting work; and this means considerable expense, which would not be incurred if gas engines were used. I am sure the question will attract the attention of engi- the house mains are led and soldered to the outside of the copper tubes only, the inner wire conductors being left untouched.

Fig. 2 shows a Crompton conduit formed of concrete, in which bare copper mains rest on glass insulators supported on oak bars. At the extreme left is shown the arrangement by which the copper strips are kept from sagging down between the insulators. The copper strips are passed through the bridge piece, which is insulated from the cross bars by glass insulators also, and when pulled taut are nipped by the set screws, one of which is shown in the sketch, and thereby kept in position.

In Fig 3 is shown a section of the conduit used by the St. James's and Pall Mall Company. This consists of a cast-iron trough with cover, the two being joined by a red-lead joint, and bolted together. Bare copper strips are supported edgeways on porcelain insulators, bridging over the bottom of the conduit to allow of free drainage, and are held in place with wooden wedges. Between the insulators porcelain distance pieces rest on the copper strips to keep them apart, as shown in the figure.

One of the well-known Callender bitumen concrete casings is represented in Fig 4, through which insulated cables are drawn. An objection to this conduit is its perviousness to water. In tests that I have made, a block with four ducts, weighing 20lb. 8oz., absorbed 4oz. of

water during an immersion of 46 hours. Another piece, with two ducts, weighing 6lb. 13oz., absorbed 1oz. in 46 hours, the water being put in the ducts, which were plugged up at one end. In this latter piece a pin-hole was found leading from one of the ducts to the outside, through which the water leaked.

plug which, if allowed to fall, short-circuits the house mains between the points F and G. The primaries and secondaries of the two small transformers are connected up so that the E.M.F.'s of the latter oppose each other, and, being equal in magnitude in the normal state of working, consequently produce no current in the fuse circuit.

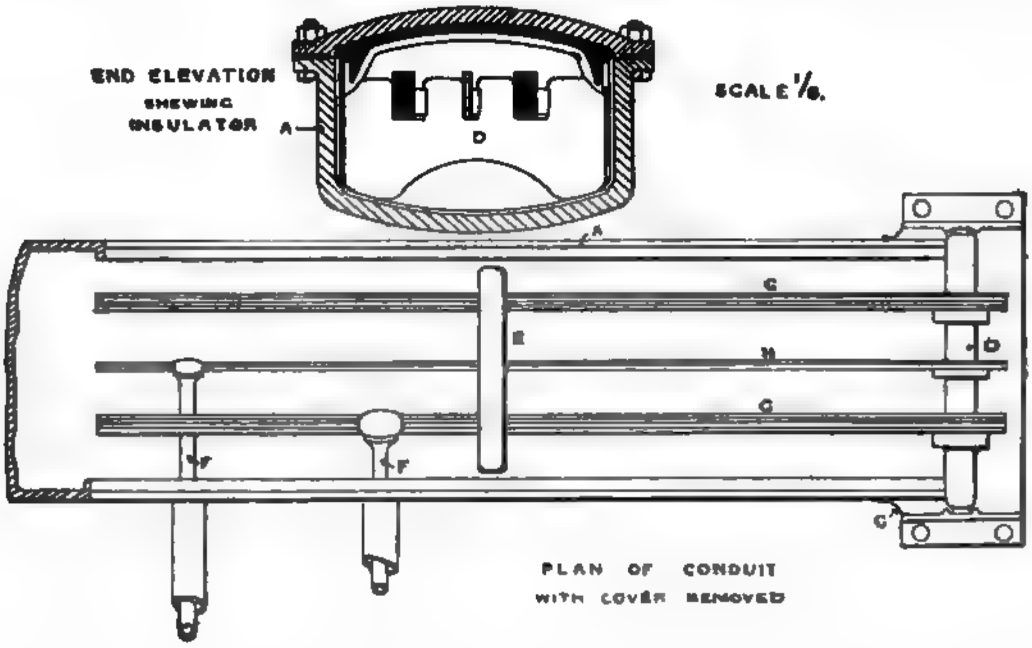

FIG. 3.

Lastly, in Fig. 5, we have the Macdonald conduit. This is made of creosoted wood, and consists of three or more pieces, joined by tongues running the whole length of the conduit. The labour of laying this conduit is small, and the number of ducts can be increased by merely adding centre pieces, the pieces being laid so as to overlap at their ends, as shown, thereby forming a compact whole.

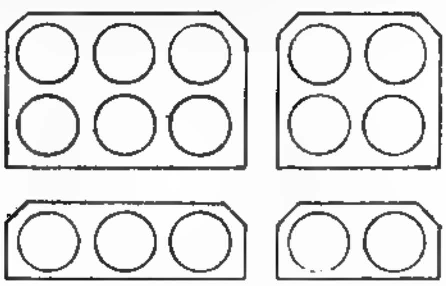

FIG. 4.

The safety device for alternating circuits I mentioned, of which a diagram is shown in Fig. 6, consists in a means for cutting off the supply to a house when there is a leakage on any circuit, or a breakdown of the insulation of

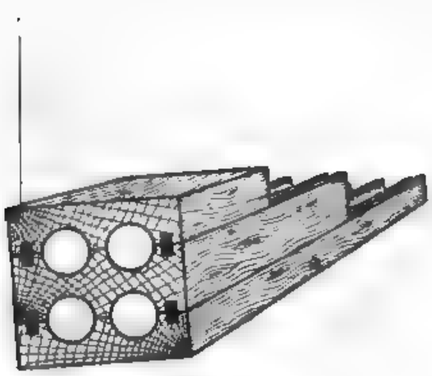

FIG. 5.

the house transformer. A and B are the primary circuits, and C, D the secondary, of two small but similar transformers, the primaries being in series and placed as a shunt across the house mains, the secondaries also being in series but forming part of a distinct circuit, in which is included a fuse, as shown, on which is suspended a

The junction of the primaries is at all times connected to earth. Now suppose a leakage occurs on the lower wire of the lamp circuit. This will upset the balance of the two transformers, by reducing the current passing through A, consequently the E.M.F.'s in the secondary circuits of the transformers will not now be equal, but that in D will overcome that in C, and a current will pass through the fuse and blow it out, allowing the plug to fall and short-circuit the house mains, the result being that the main fuse (not shown) will be blown out and the supply to the house be cut off. The same thing will result if the

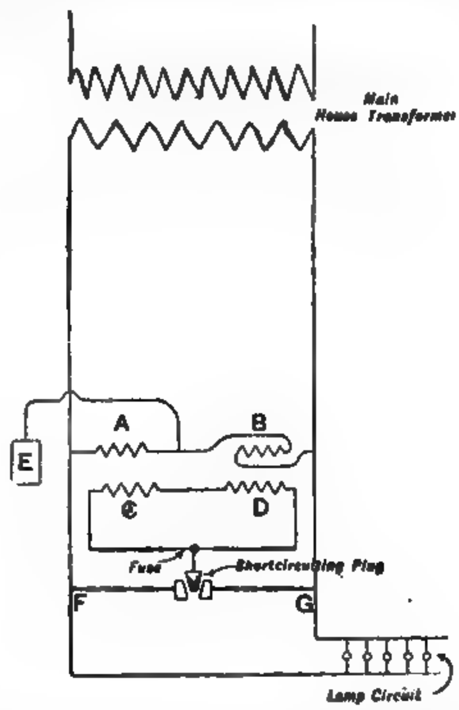

FIG. 6.

pressure rises at either terminal of the secondary of the main transformer, owing, say, to a leakage from the primary to the secondary. In the actual apparatus there is a third block, connected to earth, that the short-circuiting plug makes contact with when it falls, thereby putting the house circuits to earth effectually, and minimising all risk from shocks.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 10d.	9s. 11d.	19s. 10d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

FLASHING.

Unless we are in error, the method of "flashing" so extensively used in the preparation of incandescent lamp filaments will become public property during this November. It was in November, 1878, that Cheesbrough took out the patent for Sawyer. This was the patent round which no infringers could get. Many attempts were made to prepare suitable filaments without flashing, but it may be taken for granted that all such attempts failed. The existing incandescent electric lamp is due to a triumvirate—Sawyer, Edison, Swan. If we were sure no offence would be taken where none is intended, we should define each of these men's work — but such definitions are usually taken in bad part; however, in our opinion Swan provided the filament, Sawyer provided the perfecting part, and Edison supplied the renown required for commercial success. Lane Fox in a measure was before either Edison or Swan, but with every desire to see something in Lane Fox's patent of 1878, we are perforce compelled to acknowledge being so dense and blind as to find absolutely nothing in the shape of an incandescent lamp that had not been suggested before. Hence we cannot include this name in the list of pioneers. Taking the original specification—not amended, because the amending shows information subsequently acquired—the patentee produces a light by passing "the electric current through a thin strip or wire of some suitable material, for which purpose" he prefers "to use an alloy of platinum or iridium." In order to prevent deterioration, he sometimes surrounds "it with an atmosphere of nitrogen gas." There is no claim made for an incandescent lamp in this specification, so we think—especially as there is a specific renunciation of any such claim in the amended specification—that Mr. Lane Fox cannot be described as a pioneer, nor classed with the triumvirate we have named. The history of the modern lamp begins with the work of Sawyer, Edison, and Swan. Up to that time incandescent lamps had been suggested and made, but not with a filament of carbon as we know a filament now. The carbon was cut down and turned to the required size from large pieces, not made as a filament. Retort carbon was most often used, and suggested to be used, but this was outside a filament. Swan's work on carbonised paper, cotton, etc., on parchmentised material, furnished the germ of the filament, and we make bold to say that without Sawyer's flashing process the filament would not be so good to-day as it is. Edison's paper to the American Association for the Advancement of Science in September, 1879, showed his experimental position at that time, but in his results he was probably indebted to Sawyer, who in 1878 took out a patent to expel gas from a filament by heating it when in a globe containing a carbon preservative, and continuing the process of forcing a fresh carbon preservative atmosphere into the globe till the filament was freed from all gas. It was in 1879—or a year after Sawyer—that Edison took out a patent for a somewhat similar process to the above. He heated the filament in a globe from which the

air had been exhausted, and continued the process of exhaustion till the filament was freed from all gas. In 1879, also, Edison took out a patent for a mould for carbonising a whole material; while in 1880 Swan has two patents — one for baking filaments in powdered charcoal or carbon, the other for the parchmentising of material for filaments. We cannot see where this parchmentising process differs from that of Gaine thirty years before—a process fully described in various publications, and applied to paper and vegetable fibres. The application of parchmentised material to the use of incandescent lamp making was Swan's, and we think all the credit of this is due to Mr. Swan. Edison, as is well known, was indefatigable in trying everything he could lay his hands on, and ultimately preferred bamboo. However, we are entering more into history than we at first intended. Sawyer's, or Cheesbrough's, "flashing" patent is numbered 4,847 of 1878—hence the patent lapses this year, and, as above stated, in November. Many people fancy that they have discovered some kind of filament outside the patents of Edison-Swan, and that with the end of the Sawyer patent process they will be able to start manufacture. In our opinion, there can be no real competition with the Edison-Swan combination till the lapse of patent No. 250 of 1880—that is, till the beginning of the year 1894—say, about eighteen months from this date.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SPEED OF ELECTRIC LAUNCHES.

SIR,—On this subject you published some remarks by Mr. Magnus Volk, in your impression for the 16th inst., commenting on some of the claims made with regard to speed of electric launches, based, apparently, on the assumption that the power required for higher speeds is greater in proportion to the square of the increase. If this has been assumed, it is another illustration of the inadequate estimates which have been made of the power required from electric motors to do different kinds of work. Every ship has its own speed and power coefficient, but neglecting this variation between the performance of different vessels, or with any vessel at greatly different speeds, the power required increases as the cube of the speed. Mr. Volk's doubts are therefore well founded.—Yours, etc.,

London, Sept. 23, 1892. W. WORBY BEAUMONT.

ELECTRIC TRACTION IN PARIS.

As already mentioned in our last issue, the Northern Tramway Company in Paris is about to make a bold experiment with accumulator cars in that city, and it may therefore be interesting if a few details are given concerning the proposed tests. When the necessary permission has been obtained, two lines are to be worked. Commencing at the Place de la Madeleine, the first line will end at Saint-Denis (Place aux Gueldres), a distance just exceeding five miles. The second line, which will be nearly six miles long, will start in Paris at Rue Taitbout, and will terminate at the Patte d'Oie, at the other end of Saint-Denis. The profile of each tramway, says the *Bulletin International de l'Eléctricité*, from which we glean the following, is very uneven. There are inclines of as much as 36 millimetres per metre (say 1½in. in 40in.), whilst declines of from 20 to 25 millimetres (say ¾in. to 1in.) are numerous. It is interesting to consider in the following the work to be obtained on these lines with a car of a supposed weight of 12 tons:

OUTWARD JOURNEY.—*In Paris.*

Total maximum effort	433	kilogrametres.
" " " per ton	36	"
Maximum power	12¼	horse-power.
Average power	5·24	"
Average speed	6¾	miles an hour.

Outside Paris.

Total maximum effort	282	kilogrametres.
" " " per ton	23·50	"
Maximum power	16·71	horse-power.
Average power	2·75	"
Average speed	10	miles an hour.

COMPLETE JOURNEY FROM PARIS TO SAINT-DENIS.

Total average effort	83 37	kilogrametres.
" " " per ton	6·95	"
Average power	4·10	horse-power.
Speed per hour	8¾	miles.

RETURN JOURNEY.—*Outside Paris.*

Total maximum effort	324	kilogrametres.
" " " per ton	27.7	"
Maximum power	19·2	horse-power.
Average power	4·92	"
Average speed	10	miles.

In Paris.

Total maximum effort	332	kilogrametres.
" " " per ton	27·7	"
Maximum power	14·6	horse-power.
Average power	4·51	"
Average speed	7½	miles.

COMPLETE RETURN JOURNEY.

Total average effort	91·39	kilogrametres.
" " " per ton	7·61	"
Average power	4·51	horse-power.
Average speed	8 63	miles.

It will be seen from the above figures how varied are the powers required, independent of atmospheric conditions.

It is proposed to place 16 cars in service on the two lines, the cars being of the ordinary type and accommodating 52 passengers. The body of each car is mounted on two independent axles arranged on distinct rectangular frames. Each axle is fitted with a motor of the Manchester type, giving 10,000 watts (about 13½ e.h.p.) when running at 1,200 revolutions. The E.M.F. varies according to the speed, the maximum being 200 volts. The reduction in the speed is effected in the proportion of 10 to 1 by means of two pairs of wheel gearing, and the efficiency guaranteed between the motor axle and the terminals of the dynamo is 70 per cent. The speed of the motor, and, therefore, that of the car, is regulated by a switch having three handles. One of these allows of a change from high to low speed, the reverse operation only being possible by the aid of a key, which is not in the possession of the driver, but is kept at the barrier by an employé, who alone can perform the operation. The object of the second lever is to short-circuit one motor at low speed, if owing to an accident the use of one of the two must be discontinued. The third lever controls the direction of rotation by the reversal of the current. Each car is fitted with a Chalou brake.

The accumulators, which are contained in six boxes, are arranged under the longitudinal seats inside the car. They comprise 108 Laurent-Cèly cells, each having 12 plates and about 37½lb. of active material, and presenting a side surface of 8in. by 6 millimetres (¼in.) thick. The boxes are closed by indiarubber plates which prevent spilling of the solution through the jolting of the car. The daily journey of a horse car in Paris is 62 miles, but by the employment of storage battery cars it is expected that 80·6 miles will be covered by each car, thus requiring five tons of cells. Each car will carry 2½ tons of accumulators, and as the half day's work is about accomplished, the car will return to the depot for a freshly-charged set. The cells are made by the Société pour le Travail Electrique des Metaux at Saint-Denis, where they will be charged and transported to the cars on small Decauville waggons having movable platforms. The charging station will contain four steam engines with horizontal cylinders and Corliss gear, of 125 h.p. each, and running at from 70 to 160 revolutions; these will drive Desroziers dynamos of 60 kilowatts. This experiment is due to the enterprise of M. Broca, manager of the Northern Tramways Company.

THE LIVERPOOL OVERHEAD RAILWAY.*

BY JAMES HENRY GREATHEAD, M.I.C.E.

The question of improved and more rapid means of transit for passengers is occupying attention in many of the great cities at the present time. With the extension of areas covered the question become increasingly pressing.

In London it has been under consideration for many years, and during the last session a joint committee of the two Houses of Parliament reported favourably upon a number of proposed underground electric railways of the type of the City and South London Railway, completed and opened for traffic in 1890.

In Paris, Berlin, and Vienna, similar railways have been promoted and are under discussion; while in New York, a city long since provided with elevated railways and tramways along most of the main thoroughfares, a Rapid Transit Commission has lately reported in favour of an extensive system of underground electric railways, and in other American cities, notwithstanding the rapid development of electrically worked tramways, additional facilities in the shape of over and underground lines are being considered.

This question, then, is an important one for engineers and the iron industries.

All the proposed underground lines are, since the construction of the City and South London Railway, proposed to be made of iron, and that material must necessarily enter largely into the construction of any overhead railway.

The particular railway under discussion is composed almost entirely of wrought iron. The line, now approaching completion, traverses the whole length of the famous Liverpool Docks, a distance of about six miles (as will be seen by reference to the plan upon the wall). The extensions north and south, authorised last session, are also shown, and it will be seen that they go beyond the docks and away from the river in order to give better access between the residential neighbourhood reached by them, the docks, and the heart of the city.

With the exception of a short length where the line passes under the Lancashire and Yorkshire Railway coal sidings, the railway is, as it name indicates, overhead, and for the most part just over the lines of the original Dock Railway, which is upon the surface. The latter railway serves for the distribution of goods by horse traction, and has been used also by passenger omnibuses, with specially constructed wheels to enable them to leave the track when necessary. They will leave the rails altogether upon the completion of the overhead railway, which will afford a means of transit at least three times as rapid, when the Dock Railway will be available exclusively for goods.

The overhead railway consists generally of plate-iron girders supported upon channel-iron columns, and carrying an iron flooring, upon which the permanent way is laid direct, without the usual intervening ballast. The normal spans are 50ft., but there are some of 100ft., with bowstring girders, and others of special construction for opening and affording a passage to the docks for exceptionally bulky goods, such as marine boilers, etc., thus there is a tilting bridge near the Sandown Dock, and a swing bridge of novel construction, and worked hydraulically, crossing the entrance to the Stanley Dock. This is the only dock entrance crossed by the railway, the other docks being on the river side of it.

The columns are grouted into cast iron sockets, bedded in and bolted to masses of concrete, forming the foundation.

With the exception of some half-dozen spans, the line has been constructed without the use of scaffolding, and with very little interference with the traffic, either of the docks or of the streets.

This important end was attained by adopting a construction which admitted of each span and its flooring being put together at one end, and transported as a whole over the already completed portion of the railway.

A depôt was established at the north end of the railway, where the flooring was constructed and riveted together and to the main girders. The whole span was then raised by jacks, a steam bogey with wheels running upon the two rails nearest the main girders (and thus having a gauge of 16ft.), was run under the span, which, being lowered upon the trolley, was carried by it at such a level as to clear the main girders to the southern end of the structure. Arrived at this point, the span was slung upon a movable gantry, and by it deposited upon the columns prepared to receive it. In this manner span after span was added, as many as 10 being placed in a week, representing a length of 500ft. of railway.

Photographs illustrating the operations of construction and portions of the railway accompany the paper, and the details of construction of one of the normal spans are shown in the accompanying drawings, and do not therefore require description.

The decking is of arched plates, finishing to 2ft. 6in. wide and 15in. deep, made watertight by asphalte placed in the V channel between the arches; this form of flooring (known as Hobson's arch plate system), first used on this railway, is being extensively used elsewhere. It is for its weight of great strength and stiffness, and is readily made watertight.

The flooring is made of ordinary iron plates and tees. The plates are 46in. wide by $\frac{5}{16}$in. thick, and vary in length from 22ft. to 27ft. The tees are 4½in. by 3½in. by $\frac{7}{16}$in. section, and are of lengths corresponding to the plates. A cross-section is as shown in Fig. 1.

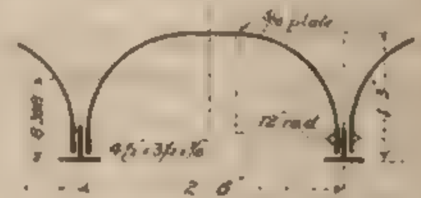

FIG. 1.

In order to ascertain the exact strength of the floor, some actual sections were tested to destruction, and the deflections at each increase of load were carefully tabulated with the following results.

Test.—*a.* Three sections of floor measuring 7ft. 6in. in width.

b. Span, 22ft., ends resting upon supports.

c. Load distributed over four points corresponding with the positions of the rails.

Test load.	Deflection at centre.
30 tons	nil
35 „	⅜ inch
40 „	½ „
50 „	$\frac{11}{16}$ „
60 „	¾ „
70 „	1⅛ „
80 „	1¼ „
90 „	1½ „
100 „	1$\frac{11}{16}$ „
110 „	2 „ (limit)

The floor plates ultimately collapsed by the total rupture of the T irons at 160 tons, and with a deflection of 10in.

It is hoped that members may be able to see the actual construction of the decking at the north end. A short description may, therefore, be of interest. The flat plates are delivered sheared to exact length and width. Six of them at a time are heated in a long oven (to a cherry-red heat), whence they are separately hauled out endways into a hydraulic press, which bends them to the required shape. After cooling upon a grid or frame, where they are tightly held to prevent change of form, they are taken to a multiple drilling machine, which drills the requisite rivet-holes (about 200) in two operations and in 15 minutes. After the end angle irons, for attachment to the main girders, are added, the decking is completed by riveting mechanically the covered plates to the T irons forming the lower member. These combined operations are performed at the rate of 40 to 45 plates per day.

There are to be 15 stations. They are built upon iron girders and columns, the platforms being about 115ft. in length by 12ft. wide, and are 3ft. above rail level. Access to the platform is gained from the street level by four staircases at the more important stations, and on each platform a waiting shed is provided with pay offices and turnstiles. An extensive carriage shed is erected near the Hornby Docks, with five lines of way running through at the same rail level as the main structure of the railway

* Paper read before a meeting of the Iron and Steel Institute.

and underneath, on the ground floor is the repairing shop, to be equipped with the necessary tools. The railway is to be worked by electricity, generated at a station, for which 12 of the arches, forming the viaduct which carries the coal sidings of the Lancashire and Yorkshire Railway, have been appropriated, near the Bramley Moore Dock, and about the middle of the line. At this station are three engines, each capable of working up to 400 i.h.p., and each driving a separate Elwell Parker dynamo. The electricity will be carried north and south along the railway by a steel conductor, placed on porcelain insulators, supported upon cross timbers between the rails of each line.

Hinged collectors of cast iron, sliding upon this conductor, will make the connection between the motors upon the train and the dynamos at the generating station. The motors are not placed (as on the City and South London Railway) upon a separate locomotive, but are carried by the passenger carriages themselves.

A train will consist of two carriages, each to seat 56 passengers, and provided with a motor at one end. The carriages will be so coupled as to give a motor at each end of the train, and the motors will be so connected together as to be controlled from either end by the driver, who will always travel at the front end, changing ends upon arrival at a terminus, and carrying with him a key, without which the motors cannot be operated.

All the carriages will be exactly alike, and will contain compartments for two classes of passengers, with through communication from end to end of the train under the control of the guard. A train loaded with passengers will weigh about 40 tons. The trains will be lighted by electricity, and are fitted with the Westinghouse brake, deriving its compressed air from a reservoir on the train, the reservoir being charged after each journey. This system of working the brakes has been found to answer well on the City and South London Railway. The generating station will contain at first six boilers of the Lancashire type, each 30ft. long by 8ft. diameter, with a working pressure of 120lb., and stoked mechanically. The engines are horizontal, compound condensing, by Messrs. John Musgrave and Sons, Bolton. It is intended to commence running with a five-minutes' service of trains, but the generating plant is designed to be capable of working a three-minutes' service, and the journey from end to end of the railway (inclusive of stoppages) is to be performed in half-an-hour. There are 13 stations upon the dock portion of the line, and a novel feature on the railway will be a system (Timmis's) of automatic signals at all the intermediate stations, in place of the ordinary signalling arrangements. These signals will be electrically worked by the trains themselves, and considerable saving in the working expenses will result.

The permanent way, it will also be noticed, is of a novel construction. Longitudinal sleepers, resting directly upon and keyed to the arched decking, support the rails and the electric conductor. As already stated, there is no ballast between the permanent way and the structure, and the working charges in connection with the maintenance and repair of the permanent way should be exceptionally light.

The total cost of the railway, including equipment, will be about £85,000 per mile. Mr. J. W. Willans is the contractor for the works, and the Electric Construction Corporation, Limited (Wolverhampton), are providing the electrical equipment and the carriages. The engineers, Sir Douglas Fox and the author, have been represented on the work by Mr. Francis Fox and Mr. S. B. Cottrell, and Mr. F. Hudleston has had charge of the work (for Mr. Willans), and to him is due the credit for the design of the tilting and swing bridges referred to. It is intended to open the line for traffic very shortly.

Ore Recorder.—Electricity does not confine its usefulness to lighting and hauling for mines, and an additional application has been found in an electric recorder for registering the output of ore which has been installed on the pithead of a Belgian lead mine. Each load of ore delivered at the top of the shaft completes a connection to an electromagnetic mechanism, and marks a red line on a sheet of paper moved by a revolving barrel in the ordinary manner of registering instruments.

THE ELIESON NEW ACCUMULATOR.

In the accompanying drawing we illustrate a new form of accumulator invented by Mr. C. P. Elieson. This accumulator is entirely on the Planté principle, and it will easily be perceived that although it is only composed of two electrodes, a large amount of surface is nevertheless provided for the storage of electrical energy. Figs. 1, 2, and 3 are the three parts composing such an element, Fig. 1 being the negative electrode, Fig. 2 the separator, and Fig. 3

FIG. 1. FIG. 2. FIG. 3.

the positive electrode. The positive electrode is inserted in the skeleton box, Fig. 2, the whole is then placed into the negative electrode. A hard rubber box is provided with a rim extending 1in. from the bottom of the box, upon which rim the negative electrode rests so as to prevent any possible short-circuiting from the agglomeration of

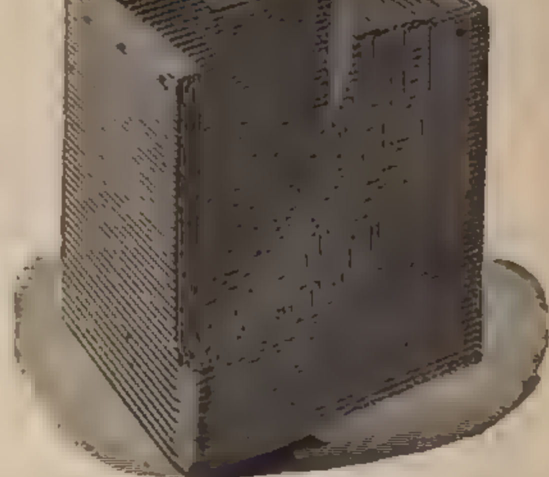

FIG. 4.

oxide dropping at the bottom. Fig. 4 gives a view of one electrode, where a portion is removed in order to show the internal construction, which is built up of a series of corrugated and perforated envelopes of thin lead. Each of these envelopes are built up on top of each other, and each corrugation is so arranged as to run across or at an angle with the corrugation of the next envelope; in practice, nine of such envelopes compose one electrode.

The positive electrode, 5in. by 3¾in. by 8in., possesses 4,000 square inches of exposed surface, the negative electrode measures 6½in. by 4½in. by 8in. in. The lugs which are on each electrode run right to the bottom, and are burnt through and through in order to secure a perfect metallic connection with each envelope. The weight of the two electrodes is 12½lb., or 23lb. including box and electrolyte. It is claimed that such an accumulator requires very little attention, and that the positive electrode will hardly require renewing after 12 months' hard work. The formation process is carried out in the usual way, partly chemically and finished off electrically. The storage capacity of this cell is about 100 ampere hours, but the formation can be stopped at 60 or 80 ampere hours, as it will soon increase in its capacity while in actual work.

THE PROBLEMS OF COMMERCIAL ELECTROLYSIS.*

BY J. SWINBURNE, MEMBER.

It would be idle to attempt to go over the whole subject of the technical applications of electrolysis, as, although this development of industry is of very recent growth, it is already so extensive that many of its branches demand evenings devoted exclusively to their discussion. My object is, however, to take a sort of birdseye view of the subject, and, if possible, to try to foresee the directions in which others must seek for future developments.

There is a very general feeling that there is a mine of untold wealth in the application of electricity to metallurgy, but chemists are not generally electricians, and electricians are seldom chemists. It seemed, therefore, advisable to bring the paper before this Institution, in the hope that it will result in a discussion, and if it leads to the expression of the views both of electrical engineers and manufacturing chemists, and to a further approach to common ground, our time will be well spent.

However puzzling the theory of electrolysis may be, for commercial purposes it may be regarded as involving no mystery. In fact, broadly speaking, we may disregard the electrical side of the question and look upon electrolysis as a method of oxidising and reducing, and nothing more. It must be remembered, however, that there often many ways of oxidising the same substance. For instance, a sulphide may be oxidised into a sulphite or sulphate, or sulphur may be liberated. Electrolysis does not always afford the means of oxidising in the particular manner desired. A very large number of the processes employed in chemical industry consist merely in oxidising and reducing, special conditions being arranged to suit the particular substance being operated upon. Once we take this broad view, all we have to consider is, "Which of the oxidising and reducing processes in use in chemical works can we advantageously replace by electrical methods?" In many cases electrical methods are impossible; in others they are more expensive than those at present in use; but it is hardly too much to say that in an enormous number electrolysis is destined to play a leading part in the near future.

Take, for instance, the case of reduction. This is almost universally effected by means of hot carbon, and at first sight it seems unlikely that it could pay to burn the carbon under a boiler, and get a small percentage of the energy back in the electrical form, and to utilise that portion alone. It must be remembered, however, that the methods of reduction by burning carbon are themselves exceedingly inefficient, and, moreover, they very often give impure products. By means of electrolysis, however, it is frequently possible to secure metals of the highest purity by direct processes. Before going further, it will be wise to form some idea of the cost of electrical energy in, say, a large chemical works. Of course "cost" is a loose term: we might calculate it from the cost of coal and labour and sundries; or we might add interest and depreciation, rent and superintendence. In all cases in estimating the cost, further additions have to be made for standing charges, advertising, profits, maintaining patents, etc. It is unnecessary to trouble ourselves about definitions of cost, for if it is stated how the figures are obtained, the selling price can be worked out and comparisons can be made.

Suppose a plant is put up to give a million watts, it will be found that if the plant is taken as running day and night, including Sundays, and if the best engines, with modern dynamos, are employed, the cost comes out about 0·25d. per kilowatt hour. This figure includes interest, and depreciation of engines, boilers, and buildings, and coal, labour, and petty stores; but does not include rent or salaried superintendence. This figure will appear ridiculous to those accustomed to London central stations; but that is because central stations work under the most disadvantageous conditions possible, while a chemical works has everything in its favour.

OXIDATION AND REDUCTION.

Oxygen.—The first obvious application of electrolysis is the decomposition of water. In an acid solution platinum or lead anodes are necessary; platinum is expensive, and lead takes a high E.M.F., so it would be best to use an alkaline solution with iron electrodes. Allowing two volts as the pressure required, the cost comes out at 5s. 7d. per 1,000ft. for the oxygen. The hydrogen is taken as valueless. As the output in oxygen must be small, we must take a much higher figure than the ¼d. per kilowatt-hour; in fact, it would be safer to double the price and say 11s. 2d. To find the selling price we must allow for packing in cylinders, and add all the trade charges, which will probably bring the price up to something like 15s. per 1,000 cubic feet. The retail price of Brin's oxygen is 2d. per cubic foot, so there would appear to be a very large margin.

Alkali.—We come next to a subject which has already absorbed an enormous amount of labour and thought, and that is, the production of caustic soda and chlorine from common salt. The Leblanc and Weldon process is exceedingly complicated and very costly, and as by simply electrolysing salt, costing about 15s. a ton, chlorine and caustic soda can be produced, it seems, at first sight, at least, most strange that electrolytic processes have not replaced all others within the last few years. Assuming that the process works, let us first form a rough idea of its probable economy. With suitable vats, and a reasonable current density, we may take it that three volts is a liberal allowance. For the ton of 75 per cent. caustic soda, we have electrical energy, £2 15s.; salt, £1 2s. 6d.; lime, £1 3s.; total, £5 0s. 6d. For £5 we have thus obtained a ton of caustic and 1½ tons of bleaching powder. We have allowed nothing for the cost of vats, for labour at the vats and in handling, or for evaporation of causticised liquor. The ordinary caustic liquor after causticising is quite weak, but electrolytic caustic can be made into a strong lye. On a small scale I have produced lye with 30 per cent. caustic. To do this the brine is electrolysed and then stirred up with more salt, and so on; the process being repeated several times. Strong caustic is a good conductor, so this method is good from that point of view as well as from that of saving in evaporation. Evaporation with a Yaryan should not come to more than a shilling or two a ton extra. It would doubtless be safe to say that, taking this way of estimating the cost, a ton of caustic and a ton and a half of bleach should be made for £6. This allows an enormous margin for expenses and for profits. This method of estimating is very rough; and unless a new process worked out in this sort of way comes out with an enormous margin, it is not likely to be worthy of serious consideration. On looking into it further, it will generally be found that when all the details of expenditure which will be necessary in practice are added, the margin, if it still exists, is too small. In fact, a new process must look marvellously good on paper to be really worth anything when tried commercially. Electrolytic soda and bleach seems to have an excessive margin, however, and we have to see whether there is any other weak point.

I believe the difficulty, and the only difficulty, lies in the anodes. Process after process is brought out, and each claims to have solved the problem of electrolytic soda by the use of some new arrangement of the porous partition, or by some other detail which can hardly make all the difference between success and failure. The various processes make a little excitement for a time, and then disappear, I believe because the anodes are destroyed.

Of course none of the ordinary metals can be used as anodes, as they are attacked at once. Platinum is generally supposed not to be attacked by chlorine, but I find that it is slowly eaten away. I would like to hear this confirmed or denied by others, for it is a very important point. On the one hand I find experimental anodes eaten away; on the other we hear of platinum anodes being used extensively in the electrolysis of chlorides. Of course, in the manufacture of such a cheap commodity as soda, the capital invested in platinum anodes would be prohibitive, and the least waste of metal would lead to ruinous expenditure. The next material to consider is carbon. In 1882 Bartoli and Papasogli pointed out that carbon was attacked when used in any solution which evolves oxygen. Without knowing of their work, I found the same thing by a series of experiments carried out in 1883. In those days it was tacitly assumed that carbon with peroxide of lead could be used in the ordinary secondary batteries, without any fear of local action. Though carbon does not seem to combine with chlorine during electrolysis, I find that it is always attacked, even in a solution of salt. I have tried every kind of carbon I can think of, and the result has always been that the anode was corroded. I do not mean to say that carbon is eaten away at a rate at all corresponding to that with which the soda is formed; in comparison the corrosion is

* Paper read before the Institution of Electrical Engineers.

slow. It must be remembered, however, that a very slow corrosion makes carbon anodes useless when the products are cheap.

Carbon is also troublesome mechanically. It is difficult to make good contacts with it, especially when there is chlorine about. Large carbon plates are also expensive. Mr. Greenwood overcomes this last difficulty by electroplating one side of a number of comparatively small plates, and then soldering them to a plate of type metal. The type metal is not exposed to the solution anywhere, else it would be attacked by the chlorine. By this means he produces a large carbon anode with a good metallic connection.

Peroxide of lead seems to present a solution of the problem. Unfortunately, however, peroxide of lead is reduced by hydrochloric acid, and it seems to be impossible to electrolyse salt without producing some free acid at the anode. Some specimens of lithanode I tried were attacked. I do not know, though, whether the inexhaustible ingenuity of Mr. Fitzgerald has produced any special make which will stand traces of free acid. I am inclined to think, therefore, that progress is barred in this direction solely by the want of a good anode. If this is the case, there is a fortune awaiting the inventor who can find something which will act as an anode in a solution of common salt.

I have tried electrolysing sodium sulphate. There is not the same margin here. You get hydrochloric acid as a by-product instead of chlorine, so that the Weldon process would still be necessary; and the sulphuric acid would have to be concentrated every cycle, in order to act on the next batch of salt. This process would, in fact, save the black ash part of the soda process, and, like all these methods, would demand carbonic acid to make soda crystals. Of course this last is not a serious difficulty, especially if quicklime is needed to absorb the chlorine. In this case I tried lead anodes, when, to my surprise, the small traces of chloride left in the sulphate corroded the lead anodes.

Paper makers use large quantities both of caustic and bleach, and they recover soda and causticise it on their works. It would therefore be an enormous advantage to be able to produce caustic and bleach direct on their own premises. I do not know if the presence of salt would interfere in any way with the action of caustic in the grass or straw boilers, but should think not. By making the caustic on the spot, a saving is effected in the processes otherwise necessary. There would be no need to concentrate the lye, or to fish out the salt that may be present. Caustic drums and carriage would be saved; but, of course, against this there may be carriage of salt. The importance to paper works is so great that it is almost a question whether it would not pay to face the corrosion of the carbons, and to arrange vats so that the anodes can be easily replaced.

In the Hermite process the chlorine is not given off, but a hypochlorite is formed. Of course, in this case caustic soda cannot be made. For paper works especially it is obviously cheaper to supply lime and get bleaching powder and caustic, than to make sodium hypochlorite only. This may, however, depend on the anodes. Platinum anodes are used in this process, and it seems to be the case that platinum is not attacked in an alkaline chloride. If this is so, it is possible to produce hypochlorite of soda, but not caustic and bleaching powder. The Hermite process is apparently commercially successful. Magnesium chloride is generally employed in the Hermite process, but I have been told that salt is now used. It has been said that electrolytic hypochlorites, especially of magnesium, have more bleaching power than the ordinary bleaching powder. Of course a sodium, or any other hypochlorite, may be formed which has twice as much of its chlorine available, when compared with bleaching powder; but this is merely an apparent gain, as it takes twice as much electricity to produce the hypochlorite. Messrs. Cross and Bevan, however, hold that the bleaching power of these compounds is not as determined by arsenious acid. They maintain that the fibres to be bleached contain some ketones or other, and these ketones absorb some of the available chlorine, especially when provided by bleaching powder; that the hypochlorite of sodium and of calcium waste available chlorine on the useless work of chlorinating these ketones, while magnesium hypochlorite devotes its whole attention to honest bleaching. Of course if it is slightly easier to oxidise the colouring matters than to attack the ketones, it may be the case that a hypochlorite of a weak base, like magnesium, may be able to bleach, but not to attack ketones. It would then be better than the hypochlorite of calcium, or especially sodium. These matters are better left in the hands of such authorities as Messrs. Cross and Bevan. They make out, also, that electrolytically prepared magnesium hypochlorite is best. This seems very strange. Of course it would mean that some other salt is really formed. The properties of a salt cannot depend on the method of its preparation, and there is no magic in electrolysis.

Potassium Chlorate.—The manufacture of potassium chlorate is carried out by electrolysing a hot solution of the chloride. The chlorate is then formed instead of the hypochlorite. This process is carried out on a large scale at Vallorbes, in France, under the direction of M. Gall de Montlaur. It is stated that they make a ton a day, 24 horse-power hours yielding 2·2lb. The power is supplied by a waterfall, so that the chlorate should be very cheaply made, if the anodes are absolutely free from corrosion. Platinum anodes are employed.

The Electrolysis of Fused Salt.

Many inventors have been at work on electrolysis of fused salt. At first sight this also seems most simple. Salt is cheap, and is fusible, and, therefore, all that has to be done is to melt it and electrolyse it, getting sodium at one pole and chlorine at the other. The sodium could be sold at a very low price for making aluminium, and for amalgamation in gold extraction, and can, of course, be converted into caustic soda or crystals as desired. Consumers of caustic would buy the metallic sodium, and would add water, thus obtaining pure caustic. The margin of profit in this case is apparently enormous.

The difficulties are, however, very serious. In the first place, sodium chloride boils at a very little above its melting point. The result is that the sodium is obtained mixed with large quantities of salt. Melted salt is by no means a convenient substance to handle. It acts on many kinds of clay, so that ordinary fireclay crucibles cannot be employed. Chlorine at a temperature corresponding to a red heat is also troublesome to deal with. It is said that chlorine will not attack a dry metal, so that iron can be used for the containing vessel. Most patentees describe vessels of iron with porcelain where insulation is necessary.

We now come to the anodes again. As there is no oxygen present, it would seem as if carbon might be used. Patentees always mention carbon anodes. Retort carbon is eaten away, and so are electric light or artificial carbon rods.

It seems strange that carbon should be attacked, and it would be well for these experiments to be repeated, to make sure that there is no error. Of course carbon is the only hope. Whether the chlorine is dry or not, metals are eaten away with great rapidity. The anodes are corroded chiefly at the surface. In addition to these troubles, the theoretical quantity of sodium is not obtained. Some people have supposed that there is a subchloride formed, and that sodium is really not a monovalent metal. This is rather an extravagant notion. I do not know why both sodium and chlorine should not be soluble in the fused chloride without forming any definite compound. So many workers have been unsuccessful with fused salt, that it looks as if there were some insuperable obstacle in the way, and it is questionable whether the ground is worth any further labour.

Electrolysis of Fused Soda.

Castner has recently proposed to produce sodium cheaply by the electrolysis of fused caustic. The temperature is to be high enough to fuse the caustic, but not high enough for the sodium to decompose the fused hydrate forming oxide. Whether this process has had any success commercially, I do not know.

Aluminium.

The extraction of aluminium has long been an important problem. The old method was to replace aluminium in its chloride by means of sodium. This involves the manufacture of metallic sodium, and of the anhydrous chloride of aluminium. The anhydrous chloride cannot be obtained by evaporation of its solution, as the solution gives off hydrochloric acid and leaves alumina; otherwise the anhydrous chloride would be quite cheap. The price of sodium has been reduced recently by the Castner process, but the extraction of aluminium by ordinary means is still so expensive that electrical methods can compete.

It seems to be impossible to deposit aluminium from any of its solutions, so fused salts have to be employed. The electrolytic processes differ in detail only. The electrolyte is cryolite, or a solution of alumina in cryolite. If cryolite is electrolysed, aluminium is deposited, and fluorine is presumably evolved at the anode, which is made of carbon. I have not seen any account of how the fluorine comes off. Yet in some processes it is stated that cryolite is electrolysed by itself. In the Minet process the solution of oxide is employed, and aluminium is deposited, and the anodes are burned away by the oxygen, giving off, according to some accounts, carbon dioxide, but probably the monoxide in fact. The chief difficulties in the electrolysis of cryolite solutions are due to the cryolite itself, as it attacks all the substances commonly employed for making crucibles. It is therefore usual to use cast iron to make the containing vessels or vats, and to heat the electrolyte by electrical power from the inside.

Minet uses iron vats, and arranges a shunt-current, which makes the vats to some extent cathodes, so that they are not attacked by the electrolyte. Presumably, fluorine is soluble in fused cryolite, and attacks iron. By making it a cathode it is always coated with aluminium, so that any fluorine is taken up in dissolving off some of this aluminium. The importance of preventing the corrosion does not lie so much in the slight saving

of iron as in the avoidance of any deposit of this metal in the aluminium. The great difficulty is to get the aluminium pure, and any trace of iron reduces its value for most purposes very greatly. Minet reduces the melting point of the electrolyte by the addition of common salt. In the Hall process, carried on at Pittsburg, the electrolyte is practically the same. Calcium fluoride is used to mix with the cryolite, or calcium chloride. The Kleiner, and, I believe, the Hall, processes, are carried on in England. The processes have so often been fully described elsewhere, that I need not discuss them at any length here. There is still a great demand for cheaper aluminium; and there is much to be done in making it pure. Aluminium has a strong affinity for silicon, and small percentages of silicon and iron are generally present, and are very deleterious.

MAGNESIUM.

This metal is closely allied to aluminium, and is similar with regard to its anhydrous chloride. There is not the same demand for it, as either it does not give remarkable alloys like those of aluminium, or they have not been investigated. It is said to be made on the Continent by electrolysing the double chloride of magnesium and sodium or potassium obtained from the mother liquid after evaporating sea water. The double salt can apparently be rendered anhydrous without the formation of much magnesia.

ZINC.

Proposals have been made to deal with zinc ores electrically. The blend is to be roasted into sulphate, and the solution dissolved and electrolysed. A great difficulty arises in the deposition of the metal. It comes down in trees. Kiliani proposed to use high current densities, holding that zinc then comes down in the reguline state. Watt prefers to use acetate of zinc as the electrolyte; and alkaline solutions, such as zincate of soda, have also been proposed. I am not aware that zinc has been deposited commercially. Similar processes have been proposed for dealing with the silver zinc alloy produced in the Parkes or Karsten desilverisation process.

LEAD.

So far little has been done in the way of dealing with lead ores electrically. It has been proposed to make anodes of galena, and to work with lead nitrate as electrolyte, but I have not heard that any such process has been carried out successfully. It is hardly likely that it could, as lead forms troublesome trees in acid solutions. Anyone who has worked with solutions of such salts as lead nitrate would be inclined to give up all hope of obtaining anything like a reasonably compact deposit of lead.

The extraction of silver from lead by the Pattinson process is very cumbrous and roundabout, and is, of course, expensive. Keith started a works in America for desilverising electrolytically. He used a solution of sulphate of lead in sodium acetate as electrolyte. Though the Keith process was brought out some 10 ten years ago, it does not seem to have come into general use. The deposit of lead even from such a solution as sodium plumbite is very bulky and spongy, and is difficult to deal with, as it is apt to decompose water and oxidise spontaneously during handling.

GOLD AND SILVER.

Greenwood and others have proposed to make chlorine electrolytically for catching gold by the chlorine process. As this is exactly the same problem as making bleaching powder, the same difficulties have to be overcome; so it need not be discussed further.

Mr. Crookes's sodium amalgam for making the mercury ready to seize any particles of gold, and to keep it from getting "sick," can be replaced by making the mercury itself the cathode. It is questionable whether this would be worth while, as the sodium amalgam is very convenient.

Mr. Crookes has recently brought out other electric gold processes. He finds that the particles of gold become amalgamated, and collect and get caught in the mercury, if the stamped quartz is washed in a weak solution of a mercury salt, under the influence of an alternating current of small frequency. It is difficult to see how the alternating current works. Unless the current density or the resistance of the electrolyte is something fabulous, there cannot be any current in the small particles of gold, as the minutest polarisation would make all the electricity flow by the electrolyte, and not by the little pieces of gold, even though they are very much better conductors.

(To be continued.)

Colliery Explosion. – Every serious colliery explosion is a chance that ought to be taken by business managers of electric lighting apparatus to push the advantages of electricity. The recent Park Slip explosion has been the occasion of remarks in the local papers upon the desirability of introducing portable electric lamps, and a short notice sent round to the papers of the district would be sure of gaining insertion and creating interest. Electricity is destined to provide greater safety and better facilities in colliery work, and the use of every opportunity should be taken to force home this fact.

TRADE NOTES AND NOVELTIES.

HOLDEN, DRAKE, AND GORHAM'S NEW ELECTRICAL RECORDING INSTRUMENTS.

The instruments which are now introduced by Messrs. Drake and Gorham are said to be free from many of the defects of design, which would cause readings in many existing instruments to differ from the indication of standards with which they might be compared. The new series of instruments includes the following: 1. Recording ammeter, hot strip principle for either direct or alternating currents, with continuous record. 2. Recording voltmeter: electromagnetic with moving coil, open reading for direct currents with intermittent record. 3. Recording ammeter, dead beat, electromagnetic for direct currents, with continuous or intermittent records. 4. Recording voltmeter, dead beat, electromagnetic for direct currents, with continuous or intermittent record. 5. Recording

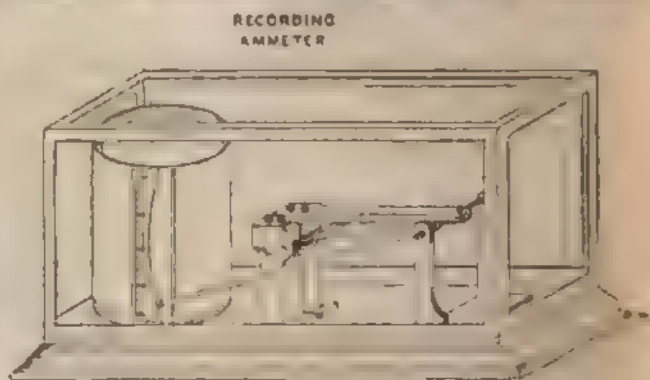

FIG. 1.

ammeter, frictionless, dead beat, with photographic continuous record for direct currents. 6. Recording voltmeter, frictionless, dead beat, with photographic continuous record for direct currents. 7. Combined recording ammeter and voltmeter, dead beat, frictionless, with intermittent photographic record for direct currents. 8. Recording ammeter, frictionless, dead beat, with photographic record for alternating currents. 9. Recording voltmeter, frictionless, dead beat, with photographic record for alternating currents.

The hot strip recording ammeter, for either direct or alternating currents, is illustrated in Fig. 1, and the principle employed in the working portion is clearly shown in the diagram of Fig. 2. Here we have two metal strips, A and B, as shown, of the same length, section, and material. These strips are fastened together by rivets, or otherwise secured at the point E, and also rigidly secured at C and D. If not fastened together at E, they might be supposed to be capable of turning about the points C and D, describing the arc C_1 and D_1 respectively. But the strips are rigidly connected at E, and, therefore, if only the upper strip, A, is caused to extend by a rise of temperature in

FIG. 2.

it, produced by the passage of the current, the position which the system of strips will be forced to take up will be one in which the equilibrium is obtained, and this position will manifestly depend on the actual amount of extension of the top strip. For instance, suppose that the amount of extension of the top strip, A, is equal to the length of the line F G, then the dotted line, C G D, will represent the position of the system when the strip A has extended by that amount; and, moreover, it is obvious that this position will be the only one in which equilibrium is produced by a certain definite current in the strip A. It may, therefore, be said that the position is dependent upon a certain current. It will be understood that a rise of temperature in both strips simultaneously, such as would be produced by atmospheric causes, will not affect the system at all, since each strip will lengthen to the same extent independently, and there will be no turning movement whatever. The record is made on a piece of corrugated paper attached to a vertical drum revolved by clockwork (at a rate which is regulated to suit requirements), by means of a pen containing aniline ink, giving a continuous record. The

pen is attached by an aluminium arm to an arbor, which is turned through a greater or less angle according to the amount of expansion of the strip. A fixed scale close to the pen enables the amount of current passing at any moment to be read by the eye. This instrument is suitable for alternating or direct-current circuits. It has no errors and takes little power; on the other hand, owing to the rigidity of the system of metal strips, it is free from the errors which arise from the friction of the pen upon the paper, and form a source of inaccuracy in most of the recording instruments employed at the present time. The width of the paper strip may be from 3in. to 6in. according to whether a very open scale is required or not.

The feature of the recording voltmeter with moving coil, for direct currents, is its extremely open reading, which combined with its frictionless action, owing to the intermittent record which it is caused to make by means of an accessory electromagnet, renders it extremely valuable for checking small variations of potential. The electrical portion of the apparatus

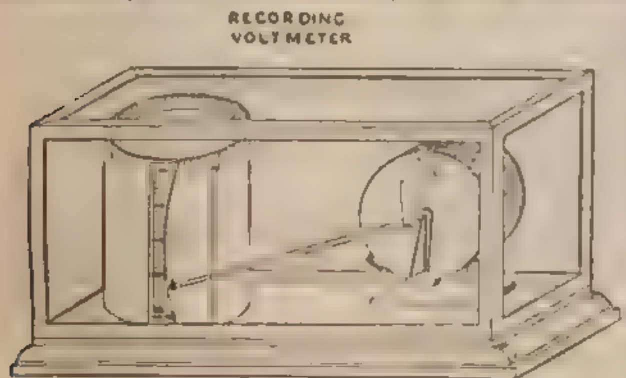

FIG. 3.

consists of a coil, mounted on an arbor working in jewelled mercurial bearings, and moving in an extremely powerful magnetic field. The pen is intermittently pressed against the paper by means of an accessory electromagnet in the base of the instrument, worked by means of a main current or by a single separate cell if desired, the contacts controlling this movement are carried by the clockwork in the drum.

The electrical portion of the dead beat recording ammeter for direct currents is a modification of the well known dead-beat ammeter sold by Messrs. Drake and Gorham; the recording portion can be fitted for continuous or intermittent records, the latter system avoiding the friction on the paper entirely. It is similar in external appearance to Fig. 3.

The dead beat recording voltmeter for direct currents, Fig. 3, differs only from the above in the proportion of the various parts and in the winding. It is remarkably free from hysteresis errors, and is probably more accurate than any recording instrument in use at the present time, though not so accurate as the photographic instruments which we describe below.

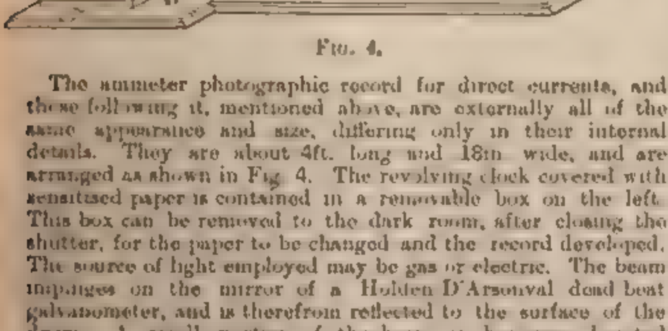

FIG. 4.

The ammeter photographic record for direct currents, and those following it, mentioned above, are externally all of the same appearance and size, differing only in their internal details. They are about 4ft. long and 18in. wide, and are arranged as shown in Fig. 4. The revolving clock covered with sensitised paper is contained in a removable box on the left. This box can be removed to the dark room, after closing the shutter, for the paper to be changed and the record developed. The source of light employed may be gas or electric. The beam impinges on the mirror of a Holden D'Arsonval dead beat galvanometer, and is therefrom reflected to the surface of the drum. A small portion of the beam is, however, directed upwards, and forms a visual pointer on a ground glass scale at the top of the box. The accuracy and convenience of this instrument cannot be surpassed. It is not affected by vibration, the presence of magnets, or any of the usual causes which so disturb the working of most instruments. The process of changing and developing the paper is a simple one; and, lastly, the power taken by this and the succeeding instruments does not exceed one watt.

COMPANIES' REPORTS.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

Directors: His Grace the Duke of Marlborough, chairman; J. B. Braithwaite, Esq., jun. (of Messrs. Foster and Braithwaite); E. Garcke, Esq.; Aymer H. Sanderson, Esq.; Colonel Frederick George Steuart; R. H. Van Tromp, Esq.; Edward Woods, Esq.

Third annual report to be presented to the shareholders at the general meeting of the Company to be held at Cannon-street Hotel, London, E.C., on Friday, September 30, 1892, at 3 p.m.

The Directors beg to submit the balance-sheet and profit and loss account for the year ended June 30 last. The profit and loss account shows a gross profit of £55,757. 11s. 3d., inclusive of the amount brought forward from last account. After deducting standing charges, maintenance of buildings, plant, and patents, and interest on debentures and new debenture stock, there remains a balance of £27,660. 15s. 8d. The Directors recommend that, as in former years, £3,000 be applied to reduction of property, patents, and goodwill accounts, and £800 to reduction of preliminary and other expenses account. An interim dividend at the rate of 6 per cent. per annum upon both preference and ordinary shares, absorbing £11,553. 16s. 1d., has been paid for the six months ended 31st December, 1891, and the Directors recommend that £11,553. 16s. 1d. be applied to the payment of a further dividend, making 6 per cent. per annum upon both classes of shares; the balance of £753. 3s. 6d. being carried forward to next account. With a view to providing additional capital for extensions at the Loughborough Works, and to enable the Company to deal adequately with contracts on hand for electric lighting and other work in the City of London and elsewhere the capital account has during the past year been increased by the issue of shares to the amount of £11,223. During the year the £75,000 6 per cent. mortgage debentures of the Company have been redeemed by the issue of £125,000 4½ per cent. perpetual debenture stock, of which the major portion was issued to holders of the £75,000 mortgage debentures at the rate of £110 4½ per cent. debenture stock for each £100 6 per cent. mortgage debenture. The amount of this premium has been added to the property, patents, and goodwill account. The capacity of the Company's works at Loughborough has been increased during the past year by the erection of additional buildings and plant, and the Company is now in a favourable position for undertaking large central station and other contracts. Further additions with a view to the concentration of the Company's manufacturing operations at Loughborough are now in progress. The locomotive and rolling stock department continues satisfactory, and important contracts have been carried out during the year. The vertical steam engines manufactured by the Company specially for driving electrical machinery also continue to grow in favour, and numbers have been supplied to other firms engaged in the electrical industry. Satisfactory advance has been made with the City of London electric lighting contract referred to in the last report, and the plant already installed is now regularly supplying public and private electric lighting in a large part of the City of London. The plant so far erected for the City of London Electric Lighting Company represents only a small portion of the total work to be done for that Company, and in view of the numerous applications which have been received for light in the City of London, it may fairly be anticipated that the work to be executed during the current year under this contract will add very materially to the volume of business. The Company has also during the past year secured large contracts from municipalities for the equipment of electricity supply stations in several of the leading towns of Great Britain; and the prospects of other local authorities deciding to carry out central station works, and of this Company sharing fully in the execution of such orders, are encouraging. The Directors deemed it advisable to make a comprehensive exhibit of the Company's manufactures at the recent Crystal Palace Electrical Exhibition, and there is every indication that the results will justify the course adopted. The whole of the cost connected therewith has been written off in the profit and loss account before arriving at the net balance shown. The Directors submit, as before, a separate balance-sheet of the Company's foreign and colonial branches at Vienna, Temesvar, and Australia. The Austrian and Hungarian businesses of the Company have made good progress during the past year. Negotiations in connection with a rearrangement of the Company's interests in both businesses are still in progress. The policy of establishing a branch of the Company in the Australasian colonies is now bearing fruit. Some important contracts and sales have been effected, and others are under negotiation. The Company own the Edison patents throughout Australasia; and recent decisions in the New South Wales courts have confirmed these patents as controlling the sole right to the manufacture and supply of incandescence lamps. Mr. E. Garcke has resigned the position of managing director, but retains his seat at the Board. Messrs. John S. Raworth and R. Percy Sellon, who formerly held the positions of chief engineer and assistant manager respectively, have been appointed joint managers. Messrs. E. Woods and E. Garcke retire by rotation, and offer themselves for re-election.

BALANCE-SHEET, JUNE 30, 1892.

Dr.	£ s. d.	£ s. d.
Authorised capital	750,000 0 0

NEW COMPANIES REGISTERED.

Bates Steel Company, Limited.—Registered by H. Ogden Mellor, 27, Clements-lane, E.C., with a capital of £350,000 in 35,000 shares of £10 each. Object: to carry into effect an agreement, made between W. R. Renshaw of the one part and this Company of the other part, for the acquisition of certain patents, patent rights, etc. (granted to F. G. Bates), relating to an improved process for the preparation of material for use in converting iron or low-grade steel into high-grade steel, and to develop and turn to account the same; as steel makers and converters, coal and iron masters, engineers, tool makers, chemical manufacturers, colliery proprietors, metallurgists, etc.; and to carry on the business of an electric light and power company in all its branches; to acquire lands and other property of any description, and to develop and turn the same to account in such manner as the Company may deem expedient; to search for and render marketable cryolite or any other material containing alumina, iron, etc.; to establish and maintain railways, tramways, wharves, piers, etc., roads, watercourses, etc.; as shippers and shipowners; as company promoters, and the general business of a financial agency. There shall not be less than three nor more than seven directors; the first to be elected by the signatories to the memorandum of association. Qualification, £1,000. Remuneration: Chairman, £375 per annum; ordinary directors, £250 per annum each.

Electro-Alkali Company, Limited.—Registered by Messrs. Bonner, Wright, Thompson, and Co., 165, Fenchurch-street, E.C., with a capital of £160,000 in £10 shares. Object: to adopt and carry into effect an agreement, expressed to be made between the Electric Construction Corporation, Limited, of the one part, and this Company of the other part, for the acquisition of certain patents, patent rights, licenses, etc. (referred to in the said agreement), relating to any chemical, electrolytical, or electro-chemical process, or to any apparatus, implements, or machinery used in connection with electricity, and to develop and work the same. The first subscribers are:

	Shares.
W. Young, 109, Crofton-road, Peckham-road, S.E.	1
F. J. Allen, 14, Trelawn-road, Brixton	1
F. Virgo, 98, Earl's Court-road, S.W.	1
W. H. McCarthy, 101, Brook-street, Kennington	1
J. Payne, 5, Richmond-terrace, Clapham-road, S.W.	1
J. R. Threadgold, 19, Shenley-road, Camberwell, S E.	1
S. T. Bishop, 6A, York-grove, Peckham	1

There shall not be less than three nor more than seven directors; the first are to be nominated by the signatories to the memorandum of association. Qualification, £100. Remuneration, £100 each per annum, with 10 per cent. on the gross profits of each year, and 10 per cent. on the amount realised by sales.

Electricity Supply Company of Croydon, Limited.—Registered by Harrison and Robinson, 263, Strand, W.C., with a capital of £40,000 in 7,900 ordinary shares and 100 founders' shares of £5 each. Object: to establish at Croydon a central station for the supply of electricity, and to maintain and carry on the same. With slight modifications, the regulations contained in Table A apply.

London Health Electrical Institute, Limited.—Registered by Mann and Taylor, 109, New Oxford-street, with a capital of £10,000 in £1 shares. Object: to carry into effect an agreement, made September 16, between G. I. Spalding and M. C. Spalding

of the one part, and T. J. Hartshorn, on behalf of this Company, of the other part, for the acquisition of the business now carried on under the style of the Magneto Electric Battery Company and the London Health Electrical Institute, or the Health Electrical Institution of London; to provide for the treatment of diseases by means of appliances employing electricity, etc. The first Directors are G. I. and M. C. Spalding. Qualification, £2,000. Remuneration, £600 and £300 per annum respectively.

BUSINESS NOTES.

Commercial Cable Company. The West-end office of this Company has been removed to 1, Northumberland avenue.

Agent Wanted.—Messrs. Clarke, Chapman, and Co. desire to appoint an agent, on commission, in the Birmingham district, *vide* p. xvi.

Belfast.—The Lighting Committee of the Belfast Corporation has decided to introduce the electric light to a limited extent, as an experiment in illuminating the city.

Western and Brazilian Telegraph Company. The receipts for the week ending September 23, after deducting the amount payable to the London Platino-Brazilian Company, were £4,009.

Coventry.—At the Coventry County Council on Wednesday, the Electric Light Committee reported that schemes and estimates for a central electric light station had been received from six firms.

City and South London Railway Company. The receipts for the week ending September 25 were £768, against £708 for the same period last year, or an increase of £60. The total receipts for 1892 show an increase of £845 over those for the corresponding period of 1891.

Workshop Lighting.—Messrs. Harpers, Limited, of Aberdeen, have placed an order for the electric lighting of their new workshops with the General Electric Power and Traction Company, Limited, of Kentish Town, London. Two of the new shops to be thus lighted are each equal in size to the Bethnal Green Museum.

Dundee.—The Eastern Club managers have given an order to the Dundee Gas Commissioners to light two flats of their buildings with the electric light. This is the first order the Commissioners have received since the electric lighting works were constructed. The system of mains in the central part of the town is being laid down.

Frizington. The Frizington Local Board have authorised Mr. Richards to obtain a water gauge and test the pressure of the water pipes, so as to judge whether they can obtain enough power to drive the electric light. The other members thought Mr. Richards should wait to see the result at Whitehaven, but he was accorded his water gauge.

Police Signal System. At the Liverpool Watch Committee, on a report from the head constable, it was resolved that it be recommended that an agreement be entered into with Messrs. Siemens Bros. and Co., Limited, for the hire of 50 signal lamp posts, together with the use of one office indicator for receiving messages from such lampposts.

Anglo American Telegraph Company. The Directors of this Company have declared an interim dividend for the quarter ending September 30, 1892, of 12s. 6d. per cent. on the ordinary stock and 25s. per cent. on the preferred stock, less income tax, payable on November 1 to the stockholders registered on the books of the Company on September 30, 1892.

Dublin.—The Electric Light Committee are advertising for a clerk and storekeeper at a salary of 30s. per week. Age not to exceed 30 years; a knowledge of electricity desirable, and a preference will be given to candidates who can write shorthand. Full particulars can be obtained of Mr. John Beveridge, town clerk, City Hall, Dublin. Applications are to be sent in by Oct. 3.

Eastern Telegraph Company, Limited. The Directors of this Company announce the payment on October 14 of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares for the quarter ending Sept. 30; and the usual interim dividend of 2s. 6d. per share on the ordinary shares, tax free, in respect of profits for the quarter ending June 30.

Maidstone. The Local Board have decided to engage Mr. W. C. Hawtayne to carry out the electric lighting scheme for the borough, at a salary of £300 per annum, on which terms he will be engaged for at least 12 months after he has got out the plans and put the scheme into working order. It is anticipated that the carrying out of the works will involve an expenditure of about £12,000.

Windsor.—The Town Council of Windsor invite tenders to supply with gas or other material for lighting, and to light, extinguish, and keep clean the public lamps in the district of the borough of New Windsor. The tenders to be at per lamp for lamps lighted at sunset and extinguished at sunrise, for one year. Tenders to be delivered at the town clerk's office, 4, Park street, Windsor, by October 8.

Barnet. At the last meeting of the Barnet Local Board a letter was read from Messrs. Joel protesting against the charge of £17 for the removal of the electric light posts, and asking for details and vouchers. They objected that the charge of £8. 15s. 2d. for kerbing was exorbitant, as the person who removed the posts was employed to fix them, and had the kerbing in his possession. The clerk was instructed to furnish Messrs. Joel with the details asked for.

Mexican Telephones.—It is stated that a new telephone company is to be started in Mexico, of which the promoters and managers will be Ernest and Enrique Ascorve. The capital will be 100,000dols. The name of the company is to be Compania de Telefonos de Mexico, and is to be composed entirely of Mexicans, from manager to smallest shareholders, though this is likely to be of doubtful advantage.

Bournemouth.—At the Bournemouth Town Council meeting last week, in reply to Councillor Trevanion, Alderman Ridley, chairman of the Lighting Committee, stated that the subject of the lighting of the pier, gardens, and public offices by electricity was under consideration. They had found that the lighting of the public offices alone was much more economically carried out by the company than by the Corporation. Councillor Hankinson said if the gardens and pier were lighted he had no doubt the cost would be less.

Colliery Engineering.—Mr. Albion T. Snell, since he severed his connection with the General Electric Power and Traction Company, some five months ago, has been practising as a consulting engineer, making a specialty of electrical transmission of power, more particularly with reference to colliery and mining work. This is a field in which he has had many years' practical work. And in order to ensure the highest degree of efficiency in work entrusted to him by colliery proprietors and mining managers, he is consulting with Messrs. Walker and Hardwick, mining and civil engineers, of Sheffield and London. Mr. Albion T. Snell's offices are at Suffolk House, Laurence Pountney hill, London, E.C., and North Church street, Sheffield.

Beckenham.—At the Beckenham Local Board meeting a letter was read from the Crystal Palace and District Electric Supply Company, Limited, in reply to the Board's complaint as to the non-completion of the Company's mains and the supply of electricity in the Crystal Palace district. The secretary to the Company wrote trusting there would be no necessity for the Board to take any action in regard to the matter, and explaining that the delay had been caused solely in consequence of some differences of a technical character between the Company and their contractors. Some of the mains in the district had already been laid, and the work would now be immediately proceeded with. As soon as the sub-station had been completed a supply would be available for use. The letter was referred to the Works Committee.

Camberwell. At the meeting of the Camberwell Vestry last week permission was given to the Commissioners of Public Baths and Washhouses to erect two standard lamps at the corner of Artichoke row and Church street, to be lit by electricity. The new baths, Mr. Wallace stated, were to be lighted by electricity, and the Commissioners were anxious to show the parishioners that they were desirous to taking the lead in regard to electric lighting. At a subsequent stage, Mr. Wallace, on behalf of the General Purposes Committee, reported that a notice had been received from the Board of Trade revoking the Camberwell electric lighting order, 1891, as confirmed by the Electric Lighting Orders Confirmation (No. 9) Act, 1891, as from August 26, 1892. The order referred to the Camberwell and Islington Electric Lighting Company.

Fleetwood.—A note elsewhere on Morecambe shows that the Fleetwood people are wishful of having the electric light. The Highway and Lighting Committee have recommended unanimously to authorise the clerk to enter into correspondence with the following firms with reference to electric lighting, with the request for reports as soon as possible: Messrs. Hammond and Co., Mr. Thomas Barton, and Mr. E. J. Jennings. It was also determined that a special letter, with reference to reports already deposited, should be sent to the following firms: Messrs. Crompton, Messrs. Ferranti, Messrs. Gordon, the Brush Electrical Company, and Mr. J. K. Grindrod. The clerk stated that they had had replies from two firms, and the representative of one had been in Fleetwood that day. Representatives of other firms had intimated they were coming.

Volk's Electric Railway Staff's Outing.—Owing to requirements of the traffic on the Brighton Electric Railway, an ordinary "beanfeast" could not be held. Arrangements were therefore made for the party to leave Brighton on Saturday night by the 8.30 p.m. train for Newhaven Wharf, crossing by the night boat to Dieppe. Arriving there between 3 and 4 a.m. they put up for a few hours at an hotel, then spent the morning in visiting the churches and other interesting objects of the quaint old town. After lunch a drive was taken to the Forest and the Chateau d'Arques. Dinner and a stroll occupied the evening, and the party left Dieppe at 1 p.m. on Monday, arriving at Brighton at 8 a.m., the whole party having thoroughly enjoyed the outing. The weather proved very fine and the sea smooth. Mr. Magnus Volk accompanied the excursionists.

Acton. The Brentford Gas Company have raised the price of their gas 3d. per 1,000ft. When the notice of this fact was read at the Acton Local Board the idea was expressed that this would hurry on the electric light. The chairman said a good many private firms were beginning to ask what the Board intended to do with regard to electric lighting, but the Board thought it desirable to see how the experiment at Chiswick succeeded. Alderman Lingham very justly expressed the opinion that electric lighting was so generally adopted that the Board need scarcely wait for the experience of Chiswick. Mr. Bradford said country towns were very much in advance of London suburbs in this matter of electric lighting. The chairman thought the Finance Committee might

prepare a scheme whereby a contractor would undertake to supply the light on certain terms, and on the proposition of Mr. Miller, seconded by Mr Fox, the Finance Committee were instructed to consider the question and report.

Smithfield Market. – The scheme for lighting the Smithfield Market is likely to prove an interesting and striking example of the usefulness and economy of the electric light. The installation, which has been carried out by Messrs. Julius Sax and Co., has been arranged under the superintendence of Mr W. H Massey, M.I.E.E., of Twyford, and will be shortly ready for lighting. It is interesting to note that only some £35,000 capital will have been required to put down the necessary plant to bring in an annual rental of at least £15,000 during the early hours of the morning alone, so that the plant would be free to do lighting outside the markets in the evening if the terms of the concession allowed. The installation will be shortly formally opened by the Lady Mayoress, accompanied by the Lord Mayor. Under the terms of the concession the tenants will not have to pay for fixtures, and will only be charged the same price as gas. There will be in all 8,000 lamps of 50 c.p. each, and the installation will evidently become quite one of the show places of London, interesting both electrically and financially to engineers and municipal bodies.

Huddersfield. At the Huddersfield County Council monthly meeting the Gas Committee minutes showed that at a meeting of the Electric Lighting Sub-Committee on August 19, applications were submitted from Messrs. B Hirst and Sons, contractors for the joiners work, and Messrs Henry Brook and Co contractors for the ironwork at the electric lighting station, for payment on account of the materials prepared at their works for the building; and it was resolved that the borough electrical engineer be instructed to ascertain and value the amount of the work done on the contractors' premises, and grant certificates for such amounts as he might consider they were entitled to under their contracts. Alderman C. Glendinning objected to this resolution of the committee, as setting a bad precedent. Alderman Stocks explained that it was on account of a strike which prevented the electric light works from being proceeded with for nearly two months, although the material was ready at the contractors. The minutes were adopted.

Fire Brigade Telephones. – The Fire Brigade Committee of the London County Council report that on the advice of the chief officer, they have arranged that the existing link lines of telephone between districts which have been provided in case of the breakdown of the wires between the chief station and the superintendents' stations shall be abolished, and that, to guard against the possibility of such a breakdown, there shall be established between the chief station and each superintendent's station a duplicate direct line of telephone. The annual charge for the new lines is estimated at £120, but as the charge for the five link lines, amounting to £105 a year, will cease, the net annual increased expense will be only £15. They also report that they have arranged for an alteration in the method by which six of the stations in the south eastern district now temporarily connected by telephone with the chief station shall by means of a switch in the chief station be placed in direct communication with the superintendent of the district at Camberwell. The result of the arrangement will be that the annual charge for the telephone apparatus will be reduced by £10 10s.

City of London Electric Lighting Company. – This Company was formed in 1891 to supply electricity throughout the City of London. Our readers are probably fully acquainted with the history of the Company, which has a share capital of £800,000, of which 40,000 ordinary £10 shares have been subscribed and allotted, and now a new issue of 20,000 preference shares are offered for subscription. These shares are cumulative, 6 per cent. of £10 each. It is intended to issue the remaining portion of the preference shares next year. It would perhaps be injudicious of us to go far out of the details of the prospectus now put before the public, but from our own information we know that the orders in the hands of the Company are very extensive, and that they can fully employ the capital they are asking for. As will be seen from the prospectus, signed applications for current for over 40,000 8 c.p. lights have already been received, of which only about 16,000 are being supplied, and the remainder will be connected to the Company's mains as soon as the additional plant is available. We consider that this Company has as good prospects in the future as any company, of whatever kind, ever started for the production of artificial light. A great success needs only a judicious utilisation of the capital subscribed and we fancy the strong Board of Directors will be sufficient evidence to the public that the capital subscribed will be judiciously utilised.

Chatham. – In pursuance of his movement to purchase the electric lighting works by the Chatham Town Council, the Mayor of Chatham has collected some very interesting particulars, which he has embodied in a report to his colleagues, who will shortly consider the matter. The following is perhaps the most interesting portion of the report. "The Electric Lighting Acts allow local authorities who undertake to supply electricity to make a profit equivalent to 5 per cent. per annum on the outlay capital. Now if the Chatham Corporation undertake the business, it will be in a position to appropriate for the relief of local rates on the expenditure of £30,000 the sum of £1,500, which would be equivalent to a rate of 6d. in the pound. By expending an additional sum of £10,000, and so bringing the capital expenditure up to £40,000, the capacity of the Chatham station could be doubled. This would have the effect of reducing the cost of production, whilst enabling £2,000 per annum to be appropriated for the relief of the rates, and this could be still further improved upon by doing all public lighting free of cost. At the present time the Corporation of Chatham are probably spending £1,000 per annum in gas for public lighting. The £1,000 thus saved, added to the £2,000 already shown, would be a total of £3,000 per annum, which would practically be equivalent to a rate of 1s. in the pound. Under such an arrangement as the foregoing, the public streets would be far more brilliantly lighted than at present, whilst the consumers would get their light from 20 to 40 per cent. cheaper than a private company could supply it, in consequence of the Corporation being in a position to command money at a much cheaper rate."

The Blackpool Electric Tramways. An extraordinary general meeting of the Blackpool Electric Tramway Company was held at Blackpool last Saturday for the purpose of winding up the Company. It will be remembered that about three weeks ago the Blackpool Corporation took over the management of the electric trams, the Directors of the Tramway Company having accepted an offer of £15,750 for the whole of the plant, stock, etc. Mr. J. Horsfall presided, and, as chairman proposed that the Company should be voluntarily wound up. Mr Thomas Bottomley, of Marsden, near Huddersfield, seconded the motion, and after a short discussion the resolution was passed unanimously. Upon a vote of thanks being proposed a noisy scene occurred. After supporting the vote, Mr. J. Wheway said that the Blackpool Corporation had not treated the Company with the consideration they merited. The tramway had been one of the principal means of bringing people into the town, but the bargain which the Corporation had struck in purchasing the tramways reflected dishonourably upon them. A scene of confusion followed upon these remarks, the Mayor of Blackpool (Mr. H. Buckley) rising and asking Mr. Wheway to withdraw what he had said. Mr. Wheway refused, and was proceeding to remark upon a strong body of men having taken advantage of a weak body, when there were further loud interruptions, and a further objection from the Mayor of Blackpool. After the noise had subsided, Mr Wheway said he did not honour the men who had taken his property and not given him that to which he was entitled for it. The Mayor of Blackpool again asked Mr. Wheway to withdraw his remarks, but again met with a refusal. The vote of thanks was then carried, and the proceedings concluded.

Leeds. – The Yorkshire House-to-House Company promise to supply light in Leeds within two months. An arrangement has been made with the Highways Committee for Corporation staff to open up the streets for the mains, and the station arrangements are being rapidly pushed forward. The following prospectus, embodying scale of discounts, have been published:

"All accounts, whether small or large, for electricity are subject to a discount from the standard price of 8d. per unit, based upon the number of hours per quarter during which the current is used, each consumer being called upon to declare the maximum number of lights required to be in use at any one time. The scale of discounts is as follows:

For not less than	250	hours' use	(per quarter)	of the supply demanded,	10	per cent.
,, ,,	375	,,	,,	,,	15	,,
,, ,,	500	,,	,,	,,	20	,,
,, ,,	600	,,	,,	,,	$22\frac{1}{2}$	,,
,, ,,	700	,,	,,	,,	25	,,

In addition to the discounts accruing under the above table a discount of 5 per cent. will be allowed on the net amount of accounts paid within one month from the date of rendering and $2\frac{1}{2}$ per cent. on accounts paid within two months. The effect of the discounts above mentioned is to reduce the price of 8d. per unit to about the following net charges:

For	250	hours' use	(per quarter),	$6\frac{3}{4}$d.	per unit.
,,	375	,,	,,	$6\frac{1}{2}$d.	,,
,,	500	,,	,,	6d.	,,
,,	600	,,	,,	$5\frac{3}{4}$d.	,,
,,	700	,,	,,	$5\frac{1}{2}$d.	,,

It is pointed out that the most liberal discount is not necessarily given to the consumer with the greatest number of lights, but to the consumer who uses the lamps he has most regularly, and for the longest hours, as he will be the best customer. There being no storage, the machinery will be kept going whether current is used or not, and the desire of course is to foster regular demand. Shallenberger meters will be used on the Leeds system."

Morecambe. – A deputation from Fleetwood recently visited Morecambe, where the electric light is in full swing, and were welcomed by Mr Collinson, the superintendent and engineer. The station is run by a private company, with gas engines and accumulators. The dynamos are driven by three gas engines, and the company are putting down plant to make their own gas. They have sufficient machinery at present to supply 1,600 8 c.p. lamps. The station only commenced running last Whitsuntide, but already they have application for more lights than they can supply, and fresh accumulators are being put down. They have a contract with the Local Board for public lighting, but are not yet able to carry it out. The cost of the plant complete was £4,500. Some interesting statements were made by the customers as to the cost of the light, several of them stating their bills were less than for gas. Mr Cutts, chemist, was quite enthusiastic. Previously his establishment took nine gas jets, and for these he had substituted nine 8 c.p. lamps, which gave a better, brighter, and clearer light. With gas at 3s. 11d. a thousand his bill used to be £10 to £12 a year, while the electric lamps cost him 10s. a lamp, or £4 10s. a year. He was satisfied with the service, quality, and price, and recommended the Fleetwood gentlemen to go in for electric light at once. Mr. Widdup,

another customer, had only a summer season trade, using little light in the winter, and he found the two lights about equal. Mr. Bickett, another chemist, has eight lamps, making £3 12s., but as he has them on a three years' contract, with a reduction of 10 per cent. and 5 per cent. for cash, his bill amounts to £3 8s. 6d. for electric light, as against £5 to £6 he used to pay for gas. We publish these figures as given by the customers to the Fleetwood Tradesmen's Association. At Fleetwood the gas is 4s. 2d. per thousand.

Bowness. A special meeting of the Bowness Local Board last week considered the application of Messrs. R. H. Fell and Sons, Limited, for permission to lay an electric cable in the Board's district. The clerk said he had arrived at the conclusion that it would be to the interests of the Board to insist that the company should obtain a provisional order from the Board of Trade unless very exceptional arrangements could be come to with the company. Under any other circumstances the securing a provisional order would be distinctly of benefit to the Board for the reasons (1) such order could only be made with the consent of the Board and with that of the Board of Trade, and it would become the duty of the Local Board to make suggestions as to the terms of the order. (2) The order would provide for a regular and efficient supply, for the public safety, for a limitation as to the rate of charging for the light, and for an official inspection of the works. (3) Such an order would empower the Local Board to make, and bring into force, by-laws for the further security of the public safety. (4) The company would have to publish its accounts annually, giving also to the Board an opportunity of applying to the Board of Trade to vary the terms of the provisional order if it was thought desirable to do so. (5) At the end of 40 years, or such shorter period as the Board of Trade might fix, and every 10 years afterwards, the Board could take over the company's works on lease at the rate of their actual value, without allowing anything for goodwill; or they could be taken by compulsory purchase on prospective profits. After complaints upon the bad quality of the gas a discussion was held on the desirability of obtaining a provisional order. Mr. Fowkes, representative of the company, was called in, and the chairman asked him whether, assuming the company obtained a provisional order, it was likely they could come to reasonable terms for purchase at the end of seven, 14, or 21 years. Mr. Fowkes, in reply, said seven years was too short a time. The company were undertaking all responsibility and risk, and if the concern did not turn out a success, the company would lose all and the Board nothing. If the Board combined with any other authority in the purchase, he did not think the company would hesitate about arranging terms either at the end of 14 or 21 years. With regards to price, he thought the price of street lamps would be 8d. per unit, but they should not think of starting at less than 10d. a unit for the private lighting. After a prolonged further discussion Mr. Holland proposed a motion to the following effect: "That this Board recommend the County Council to sanction the laying of an electric cable along the main road through the Bowness Local Board district as required by R. H. Fell and Sons, Limited, providing the same be put down to the satisfaction of the surveyor." This was understood to include permission from the Board to put down wires along the by-roads, subject to similar conditions. The resolution was agreed to.

Government Enquiry at Whitehaven. Mr. Rienzi Walton, one of the inspectors of the Local Government Board, held an enquiry, last week, at the Town Hall, Whitehaven, with respect to an application by the Town and Harbour Trustees to borrow £14,980 for the electric lighting of the town. Mr. T. Brown, solicitor to the Trustees, explained that the scheme was divided into two parts—public lighting and private lighting. Regarding the public lamps, the whole of the present area would be lighted by electricity, with the exception of a small area consisting of some 70 or 80 houses, which were so situated as to be difficult of access and would be very costly to supply. The private supply in the first instance would be to the principal business and residential parts of the town, including the main shopkeeping streets and residences of higher value which were likely to use electric lighting. The generating station would be in connection with the sewage pumping station. At this place steam had at present to be kept up day and night in order to prevent flooding of the sewers. The building itself belonged to the Trustees, so that they would have no land to buy and no buildings to erect. All the structural expenses they would incur would be for new foundations in the present building. Two new boilers would be put in of 250 h.p. each, and these boilers would be ample for both the pumping and the electric lighting. The dynamos would be driven by four of Willans engines. If they required to extend their operations, they had room in the building for four more engines. The public lighting would be by the two-wire system, and the private lighting by the three-wire system. The public lighting would be put on and cut off direct from the generating station. The cost of the plant was estimated at £13,940, including structural alterations to buildings, which only amounted to something like £500, and all the capital outlay for the public supply for the town and the private supply contemplated under the present scheme. The public lighting would be carried out by 500 incandescent lamps, mainly of 16 c.p., with some of 32 c.p. The revenue to be derived from both public and private supply it was considered would show a profit. In the running charges he gives for maintenance of machinery and fixtures, £250; interest and sinking fund, £980; wages, £360, excluding wages on repairs; coal, £200; water and stores, £40; maintenance of accumulators, £87. 10s.; maintenance of machinery and conductors, £220. The item interest and sinking fund is reckoned at 7 per cent. on 20 years' purchase, but he asked for more than this—30, 35, or 42 years, which would make Dr. Hopkinson's estimate, the total of which is £2,057, considerably less. In the receipts there is, first, an item of £400 for pumping; this is the sum now paid, and will be saved, as the double work of electric lighting and pumping will be carried on in the same building and with the same staff. £1,000 is put down for public lighting; the amount now paid is £1,150 for gas, the Corporation owning the lamps and keeping them in order. Dr. Hopkinson's estimate for private lighting was £1,400. This was the estimate, and applications have already come in for £507, so that with the pumping, public lighting, and private customers there would be an income of £1,907 against an expenditure of £2,057. In other words, with £200 more private revenue they would have a clean sheet; and with 42 years' borrowing powers, instead of 20, the item of £980 would be reduced to about £500. So that with a fair number of years to spread over the sinking fund the scheme would show no loss. The Trustees were unanimous in thinking it was to the interest of the town to put the provisional order in force. The estimate of cost was £13,940, and the estimate for possible extensions £7,038, and on looking at the applications which had come in, Dr. Hopkinson and the chairman were of opinion that the items for engine and dynamos would be required to be extended in the immediate future; they would therefore apply for the amount for extensions as well. Dr. Hopkinson was then called. He said the engines would be of small size—60 h.p.—because the whole work was on a comparatively small scale, and it was desirable to multiply the number of units. They are condensing engines. The boilers will be Lancashire or Galloways—two at first. There is little to add to the building, the shell remaining as now. The supply is direct with accumulators. There will be four sets of engines and dynamos, and room for four more. There will be six miles of mains, mostly for street lamps. There will be 500 or 510 incandescent lamps, 16 c.p. and 32 c.p., placed on present lampposts. Each machine is 60 h.p.; the boilers would be of 250 h.p. The potential would be 200 volts for street and 100 volts for private lighting. The whole of the charges include pumping, and the town will effect an economy of £150 a year for lighting. According to the applications coming in, the extension would be certain and necessary. There was no opposition, and the enquiry then adjourned.

St. Pancras. The rapid spread of electric lighting in London is well exemplified in the St. Pancras installation. The load is even now 75 per cent. of the total amount taken up, and will soon be 100 per cent., so that further plant will be necessary. It is expected that recommendations will be made at once to the Vestry for extension by Mr. Barton, the resident engineer. The installation has some very large customers on its mains, Maple's have 800 lamps, Shoolbred's nearly 2,000, the Railway Clearing House 1,800 lamps. The output rises in an astonishing manner about 5.30 p.m., a rise from about 400 to 3,000 amperes taking place in about 10 minutes. The public lighting of Tottenham Court-road being so successful, arrangements are being made to light up Hampstead-road to The Brecknock shortly. The meters mostly used are Ferranti's meters, of which the St. Pancras Vestry are now one of the largest users, and meters up to 300 amperes are employed. It will be interesting to have a record of the terms and conditions of supply adopted by the St. Pancras authorities. They are as follows:

"*Vestry of St. Pancras. Application for Supply.*—Application for current to be made on printed form attached, to be obtained at the offices of the electricity department, Vestry Hall, St. Pancras, London, N.W., stating whether for lighting, motive power, or other purposes, the number and candle-power of lamps, arc or incandescent; if for motive power the horse-power to be developed; if for charging accumulators, etc., the amount of current required. The date to be stated when supply is required (seven days' clear notice should be given). The maximum and ordinary supply of current to be stated in every case. The voltage will be 105 or 110 volts for incandescent lamps.

"*Connection with Consumer's Premises.*—The size and position of service mains entering a consumer's premises are to be determined by the engineer to the Vestry. Where the Vestry's distributing mains are close at hand or within 30ft. of premises proposed to be lighted, no charge whatever will be made to the consumer for bringing the service mains up to the premises to be supplied. The officers of the Vestry are not permitted to perform any private work for any customer, nor can they receive any payment or gratuity under penalty of dismissal. No addition shall be made to any installation that has been tested by the Vestry's officials, until due notice has been given on the form provided; failing this, the supply is liable to be stopped.

"*Meter.*—To be placed in a convenient place, as pointed out by the Vestry's engineer, all connections on the consumer's premises to the service lines and wires to be charged to and payable by the consumer. The meters are lent on hire, at a rental, according to size of meter, from 2s. 6d. per quarter (and are kept in repair). The consumer may have his own meter, but must keep it in repair. The Vestry may test the same, and if found incorrect may charge the consumer for testing. The Vestry may also fix a meter of their own to test the accuracy of the consumer's meter.

"*Alteration or Disconnection of Meter.*—The consumer must give not less than 48 hours' notice to the Vestry that he is desirous of having his meter or meters removed, and shall in no way interfere or tamper with his meter, the Vestry being empowered to withhold the supply until it has been enquired into and rectified.

"*Inspection of Meters.*—The inspection of meters will be made monthly. The Vestry's inspector is entitled to free access at all reasonable times to take readings of meter, inspect or repair any

work in connection with the service. The inspector shall at all times carry, when on consumers' premises, his inspection book, with his authority given under the common seal of the Vestry.

"*Inspection of Meters.* The reading of the meter shall be taken as to the quantity of current used, should the consumer dispute such reading, it may be officially tested, and if incorrect, the Vestry will add or deduct for such quarter only, and if the official test certifies the meter as correct, the consumer shall bear all expenses of the testing.

"*Price.* The price for current will be 6d. per Board of Trade unit equal to 15 16-c.p. 64 watts per lamp for one hour. In cases where the current is required for motive power the Vestry hope to be able to adopt a lower scale.

"*Payment.* Consumer's account will be made up quarterly (the 31st March, 30th September and 31st December), and payment should be made within the following 10 days of the date of such account. In case of non payment the Vestry may refuse to continue the supply.

"*Contract.* The consumer will be required to enter into a written contract with the Vestry. The consumer may be required to give security for the due payment of current used, and meter rent, also the care and safe custody of the meter.—By order of the Vestry."

The application form referred to above contains space for name and address of applicant, name of contractor who fitted up installation, number of lamps (arc or incandescent), and the candle power, if motors, approximate maximum current or horse power.

PROVISIONAL PATENTS, 1892.

SEPTEMBER 19.

16692. **Improvements in electrical apparatus for signalling or speaking between ships at sea or between ships and the shore, etc.** Sydney Ferris Walker, Cardiff Electrical Works, Severn road, Cardiff.

16700. **Improvements in electric fire alarms.** Robert Wood, New Bridge street, Manchester. (Edward Hoyle, Russia.)

SEPTEMBER 20.

16768. **Electrically controlled switching apparatus for telephone exchanges.** Robert Pappotte, 31, Endymion road, Brixton hill, London.

16775. **Improvements in keys for opening and closing electric circuits.** Alexander Muir, 70, Market street, Manchester.

16786. **Improvements in fittings for the support of electric lamps.** Wolf Defries and Victor Isidore Feeny, 11, Wellington street, Strand, London.

16805. **Improved portable electric search-light apparatus.** Ronald Augustus Scott, 46, Lincoln's inn fields, London.

16806. **Improved mode and apparatus for projecting images, characters, or the like on to distant bodies.** Ronald Augustus Scott, 46, Lincoln's inn fields, London.

16820. **Improvements in telegraphic and telephonic apparatus for establishing communication between signal boxes and trains on the line.** John Draper Hewson, 22, Southampton buildings, Chancery lane, London. (Complete specification.)

16822. **Improvements in electrolytic apparatus.** Thomas Craney, 15, Southampton buildings, Chancery lane, London. (Complete specification.)

16833. **Improvements in and connected with break feed appliances for electric arc lamps.** Frederick John Beaumont, 166, Fleet street, London.

SEPTEMBER 21.

16866. **Improvements in electrode plates for secondary batteries.** Adolph Müller, 47, Lincoln's inn fields, London.

16877. **Improved signalling apparatus for telephones.** Sir Charles Stewart Forbes, Bart., 21, Finsbury pavement, London.

16878. **Improved plates for secondary batteries.** Ernest Bailey and Jesse Hall, 21, Finsbury pavement, London.

16879. **Improvements in miners electric lamps.** Ernest Bailey and Jesse Hall, 21, Finsbury pavement, London.

16893. **Process and apparatus for the extraction separation and refining of metals by electrolysis.** Donato Tommasi, 53, Chancery lane, London. (Date applied for under Patents Act, 1883, Sec. 103, 21st May, 1892, being date of application in France.)

16903. **Improvements in and relating to electric accumulators.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (Frederick Clarence Jenkins, Germany.)

16904. **An automatic switch for electric and other light applicable to a door.** James Hopwood, 77, Chancery lane, London.

16906. **Improvements connected with audible telegraphs.** Richard Robert Harper, 166, Fleet street, London.

SEPTEMBER 22.

16919. **Improvements in and connected with dynamo-electric machinery alternating-current motors transformers, manufacture of ozone and oxide of nitrogen recovery of tin from scrap, electro plating with aluminium.** James Swinburne, Broom Hall Works, Teddington, Middlesex.

16934. **Improvements in voltmeters or electrical indicators.** William Henry Thompson and Robert Thompson, 155, Fenchurch street, London.

16948. **A mode of and means for enabling boats to be propelled on navigable ways by electric energy.** Ernest de Pass, 78, Fleet street, London. (Edmond Gunsenberger, Adolphe Seiler, and Ernest Gendenin, France.)

16964. **Insulating electrical conductors.** Sydney Pitt, 24, Southampton buildings, Chancery lane, London. (Edward Crawford Davidson, United States.)

SEPTEMBER 23.

16980. **Improvements in connections for electrical accumulators and other similar purposes.** John Joseph Robins, 12, Cherry street, Birmingham.

16997. **Improvements in electric bells.** Thomas Gibson Usher, Robert Usher, and Robert Charles Usher, 46, Lincoln's inn fields, London.

17004. **Improvements in electric arc lamps.** Frederick D'Artrey Gould, 11, Brackley terrace, Chiswick, London.

17012. **Improvements in and relating to the distribution of electrical energy.** George Wilkinson, 41, Furnival street, London.

17013. **New and improved means and apparatus for utilising the expansion and contraction of liquids for the purpose of driving machinery.** Charles Mackintosh, 22, Glasshouse street, Regent street, London.

SEPTEMBER 24.

17091. **Improvements in insulating and supporting electric wires intended to act as resistances.** Rookes Evelyn Bell Crompton and Herbert John Dowsing, 55, Chancery lane, London.

17092. **Improvements in insulating and supporting electric wires intended to act as resistances.** Rookes Evelyn Bell Crompton and Herbert John Dowsing, 55, Chancery lane, London.

17093. **Improvements in electrostatic measuring instruments.** William Edward Ayrton and Thomas Mather, The Central Institution, Exhibition road, London.

17099. **An improvement in carbon electrodes.** Harry Theodore Barnett, 14, Narcissus road, London.

NOTES.

Ardrossan.—The electric light has been introduced at the Ardrossan harbour.

Toronto.—An electric tramway, five miles long, has been recently opened in Toronto.

Belfast.—The special committee on electric lighting hold their final meeting next week.

Electric Cars at Christiania.—The first electric tramcars in Norway are to be run at Christiania.

Telephones.—It is stated that the Government intend to purchase a number of the trunk telephone lines at once.

Havre.—A concession for an electric railway between Havre and Montvillier is asked by M. Burton from the municipality.

Brest.—The Société Weyher and Richemond is building three 150-h.p. engines for the electric installation of the French port of Brest.

Lecture.—In the programme for the Edinburgh Literary Institute Mr. E. A. Browning is down for a lecture on "Electric Light in our Homes."

Brussels.—The new post and telegraph office is entirely lighted by electric light, although the official opening of the building has not yet taken place.

Paris.—The accumulator traction tramway in Paris has met with an unexpected stoppage in the refusal of the Northern Railway to allow it to traverse its railway lines at the docks.

Antwerp Railway.—The negotiations for the establishment of an electric railway between Brussels and Antwerp are proceeding with vigour. M. Van den Kerchove is the promoter of the scheme.

Madrid.—A concession for an extensive system of underground electric railways in this city has been granted, says *Industries*, to an architect in Barcelona. It is generally considered that the project has little chance of being carried out.

Condensers.—M. Désiré Korda has given some attention to the effect of condensers in the secondary circuits of transformers, and has communicated a note thereon to the Académie des Sciences. Further communications are promised.

Dundee.—As will be seen elsewhere from their advertisement, the Dundee Gas Commissioners invite tenders for switchboards and instruments, to be sent in by the 22nd inst. The engineers are Messrs. Urquhart and Small, 17, Victoria-street, S.W.

Mains.—MM. Lazare Weiler and Henry Vivarez have recently published at Librarie Masson, Paris, a work on "Electric Lines and Transmission of Force." The book has an appendix giving the legislative position of electric conductors in France, Germany, and Belgium.

York.—The Corporation of York, invite by advertisement, this week tenders for the first instalment of their central station plant, and supplementary tender for extensions. Specifications and sketch plans are issued for a fee of £2. 2s., and tenders must be in by November 21st.

South American Cable.—Notification is given of the opening of a new submarine telegraph route between Europe and South America by this company's cables from Senegal to Pernambuco, in connection with the Spanish National and Eastern Companies' systems between London and Cadiz.

Zermatt.—This well-known Swiss town is to be shortly lighted by electric light, with power obtained from a glacier stream three or four miles away. A pressure of 2,200 volts will be generated by two sets of turbines and dynamos, to light at first 1,500 lamps. M. Palaz is the engineer.

Traffic in the City.—The additional centres at the Mansion House crossing in the City serve to some extent to reduce the danger to passengers at this crowded spot. But the police authorities are counting upon the facilities to be given in the intended central electrical railway to reduce the danger and discomfort to the required extent.

Aix-les-Bains.—Projects are being discussed for the introduction of electric light at Aix-les-Bains. The gas company offers an installation of 1,000 lamps by 1893, at 45f. per 10-c.p. lamp, and 55f. per 16-c.p. lamp from dusk to 1 a.m. Several companies have offered to instal a station and supply current one-third less than the gas company, and to run a day and night service as well.

Belfast.—Mr. J. C. Bretland, M.I.C.E., city surveyor of Belfast, in his address on "Municipal Affairs in Belfast," before the Municipal and County Engineers, mentions that the present cost of ordinary gas lamps is £3. 5s. each, and the charge for gas 3s. 10d. per 1,000ft. Last year the Corporation obtained a provisional order to light the city by electric light, which is now in course of being carried out.

New York.—A new departure has recently been made in New York City in the way of electric street lighting. The new arc lamps on Fifth-avenue have been placed on posts in pairs, each lamp taking five amperes at the usual voltage. Each pair of lamps is connected in multiple on a low-tension circuit, thus permitting them to be fed with current from the same mains as the ordinary low-tension domestic service, and rendering a special circuit unnecessary.

Core and Shell Transformers.—Herr L. Imhoff has recently made calculations, which have been published in the *Electrotechnische Zeitschrift*, upon the relative advantages of transformers having an inside core and those having an exterior shell with interior winding. The calculations have been carried out from the formula of Steinmetz, and go to prove the superiority of the shell type, but it would have been more to the purpose if the calculations had been tested experimentally.

Electric Lamps for Customs Officers.—It is stated that in order to avoid the possibility of explosion while "rummaging" for contraband goods on board tank and other vessels carrying petroleum or explosives, the Customs officers are in future, by order of the Customs Board, to be supplied with electric lamps of a special pattern. Ruby-coloured lights for the examination of imported cases of photographic negatives in a dark chamber are also to be supplied to obviate the risk of spoiling the plates.

Anti-Gas League.—Now here is a really good idea, which we commend to the Association of Municipal Engineers. A league is in process of formation, so we hear, in France for the association of all those towns where gas is more than a certain amount (0·20f. per cubic metre) to press for reduction, reform and the introduction of electric light. The first meeting of this anti-gas league will be held at Lyons in October. If the English authorities are active they might have a similar league going by December, and we can promise them the best wishes and good help from electrical engineers.

The Telephone in Kent.—Since the merging of the South of England Telephone Company into the National Company's system considerable progress has been marked in telephonic work throughout Kent, and an important change is now being effected in the wires. Six independent gangs are engaged upon the main trunk wires in order to set up complete metallic circuits for doing

away with the earth currents, necessitating double instead of single wires, with almost as many more posts on the line of route. The wires are also erected upon the spiral system, similar to the Paris telephone wires, to prevent induction.

Fire Risks.—A lecture was recently given to the Insurance Institute of Manchester on "Fire Risks of Electric Lighting," at the Electrical Engineering Branch of the Manchester Technical School, by Mr. Haldane Gee, lecturer in electrical engineering. The methods of procuring electricity for lighting and motor purposes were described, and the chief methods of distribution of electrical energy explained. With the aid of a number of experiments, possible danger of fire was pointed out, which in every case was due to imperfect workmanship. It was shown that the electric light was the safest possible illuminant when the installation was perfect.

Protection of Mansions from Fire.—Many Irish landowners have recently purchased fire engines or otherwise added to their apparatus for the protection of their residences from fire, and H. L. Barton, Esq., J.P., of Straffan House, co. Kildare, has just received a new "Squires" engine from Messrs. Merryweather and Sons, of London. This machine will not only throw two powerful jets for fire extinction, but can also be used to drive a circular saw, churns, cream separators, dynamo for electric lighting, and other mansion, farm, and estate plant. The engine delivers 120 gallons of water per minute and upwards, and developes over 6 h.p. The pump can be put out of gear in a few seconds and a band put on the flywheel to drive other machinery.

Rotterdam.—The Rotterdam authorities, who have a splendid opportunity along the quays, are wishful of investigating the cost of electric transmission of power for the use in cranes instead of hydraulic power. The current would also be used for lighting. They chose, out of a number, MM. Haniel and Lucy, of Dusseldorf, and the new crane has been very successful. The motor takes 140 amperes at 110 volts, and can raise a maximum of 1½ tons 60ft. in 25 seconds. The Corporation intend to supply the electric service itself, and have invited several French and German companies to tender. We are not aware whether English houses have also tendered, but the decision is to be made very shortly. Only those companies who have had experience in central station work were allowed to send in plans.

Electric Sky Advertising.—The new advertising apparatus of Messrs. Romeike and Curtice is going to beat all other schemes by its vastness and daring. To write "soap" on the clouds by electric light, or invite to Buffalo Bill everyone who glances an upward eye, is a bold scheme, and possibly will prove a nuisance. As yet the scheme is too much of a novelty to comment wisely upon. Trials are being made at Buffalo Bill's grounds, but the apparatus is hardly yet up to expectations, and a new reflector is being made by Messrs. Crompton and Co., who have the matter in hand. Mr. Curtice expresses himself as having a great belief in the project, and the large advertisers are metaphorically eyeing the new apparatus as a hungry dog does a bone. We may yet see "sunlight" shining from the skies at midnight in London.

Koechlin and Mariotti Dynamos.—Entirely new types of dynamos it is difficult, if not impossible, to make, but a considerable variation in the ordinary type is seen in those of Koechlin and Mariotti, described and illustrated in *L'Electricien* for October 1. The machines have alternate interior and exterior poles, the later type of Mariotti being a solidly designed machine with very large armature. The advantages claimed by M. Mariotti, who is engineer to the Telephone Company of Zurich, are very low speed, specially suiting the dynamo for direct coupling, the invariable position of the brushes even for greatly varying loads; also good ventilation and facility of getting at the armature. The objection is the cost for small sizes. But for transmission of force, and for large dynamos for central station work, the Mariotti dynamo seems very advantageous.

Medical "Magnetism."—The popular craze for electric or magnetic treatment of disease by qualified or more often unqualified persons is taken advantage of by many so-called "inventors and patentees." The magnetic belts have been followed by magnetic boots and brushes. Most intelligent persons are beginning to have strong doubts as to the truth of the professions of the vendors of these articles, but it is a sad thing to see the newspapers tacitly favouring their introduction. The *Bristol Times*, for instance, in a presumably editorial note, advocates the use of "magnetaire," administered by one M. Lonsdale, on the ridiculous reason that "it is the nearest approach to the principle of perpetual motion yet known!" Really a little clearer knowledge of science should be obtained by its writers at the nearest technical school, and perhaps we should have an approach to the principle of the honest policy of only writing about what is understood.

Transformers.—The article upon the efficiency of transformers which we reproduce elsewhere is worthy the best attention of electrical engineers. We doubt whether such successful results in obtaining high efficiencies at low loads of transformers have ever before been made, and MM. Hutin and Leblanc are to be congratulated on their work in this field. As will be seen, the progress made is less in any pure theoretical advance upon mathematical calculation than ordinary common sense and engineering knowledge adapted to transformer work. It is possible, as suggested, that the manufacture of transformers of high efficiency at low loads will redirect the arrangement of distributing projects to the use of separate transformers for each customer. But this is to be doubted, as the sub-transformer station is often more convenient as well as more efficient. This does not detract, however, from the extreme importance of the investigation and experiments.

Electric Traction.—The subject of electric traction is ever present in the electrical engineer's mind as the one coming important problem. How is it to be solved—overhead, underground, or storage? Therefore the announcement of a treatise on the subject of electric traction by such a competent and well-known authority as Mr. Anthony Reckenzaun, C.E., has roused a considerable feeling of interest, not only in Great Britain, but in America and the Colonies, where we are told engineers are anxiously expecting the promised volume. This work is now before us, the full title being "Electric Traction on Railways and Tramways"; illustrated. (Biggs and Co., Salisbury-court), price 10s. 6d. We are not here giving a full notice of the book; we mention, however, that the book is full of practical details, with diagrams, descriptions, and illustrations of the most interesting electric traction installations in Great Britain, America, and the Continent. It has a very complete index.

Halifax.—A recent visit to Halifax revealed the fact that although this town has 60 arcs, and some 400 incandescent lamps alight (and therefore considers itself as the best electrically lighted town in the North), yet there is really very little doing in the matter of public electric light supply. Halifax is in the peculiar position of having its borders enlarged, and a strenuous fight is looked for at the November elections. The electric light question is therefore kept in the background for the present, though the Corporation have already obtained their provisional order, and the energetic mayor, Alderman Davis,

is understood to think well of a municipal scheme. In fact, the town is pretty sure to do its own lighting. It is a very public-spirited place, and although Messrs. Blakey-Emmott, who now carry on the present lighting—and carry it on well—have made overtures, in the shape of the Halifax Mutual Electric Company, to take the lighting, it is not likely that this will be done. After November some active steps are likely to be taken, and plans on an extended scale will be required.

Discussion.—There is something about the electric light (we think it must be the gas) that makes discussions on the point very lively, not to say scandalous. We noticed the meeting at Heckmondwike last week, and gave the result of it—namely, that a new committee was to be formed. The full report of this meeting is before us, and is stigmatised by the reporter as the most disorderly meeting in the history of the Board. The simple question, Shall an electric plant be put down at the expense of the town? turned shortly into recrimination, and even "liar" was banded about by two councillors. Fie! gentlemen; this is certainly not seemly. The difficulty appears to here, as elsewhere—"gas shares," mingled with the sentiment expressed by Mr. Crabtree, that "at my time of life I am not going to charge my brain with electricity." There would seem to be an opening for the sale of a good elementary primer during these town council discussions. A prospectus sent to each councillor of the towns discussing electric light might lead to a more intelligent and less personal discussion.

Incandescent Lamps.—A carefully-carried-out series of experiments on the life and efficiency of incandescent lamps, by Ch. Haubtmann, is given in *L'Electricien* for Sept. 24. The article is illustrated with a large number of tables and curves dealing with tests of incandescent lamps of the following makes: La Française, Gabriel, Swan-Edison (French and English), Khotinsky, Cruto, Allgemeine, Hongroise, Zurich, Gerard, and Siemens. Several of the nominal 16-c.p. lamps gave an average of 8 c.p., 12 c.p., or 13 c.p. The best result seems to have been obtained with a "Gabriel" of nominal 16 c.p., which started at 18 and ended at 14·98 (average 16 c.p.), after burning 1,800 hours. This lamp took 63 watts. The English Edison-Swan came next with a start of 18·4, ending at 13·9 (average 16 c.p.), 60 watts, lasting 1,200 hours. The Hongroise nominal 16-c.p. started at 21 c.p. and dropped to 13·25, using 62·5 watts for 1,250 hours. The Allgemeine 16-c.p. lamp only started at 15 c.p., and dropped to 12 c.p., lasting 1,000 hours, but then it only took 50 watts. Other types took even less and died in 600 hours. The article is very interesting from both manufacturers' and consumers' points of view, and is worth further attention.

Workshop Lectures.—The following syllabus of a set of workshop lectures which are being given week by week at Messrs. Blakey, Emmott, and Co.'s works by Mr. J. H. Rider, M.I.E.E., will be found interesting. The course comprises lectures on Current and its Measurement, Galvanometers, E.M.F., Difference of Potentials and their Measurement, Resistance and its Measurement, Batteries—Primary and Secondary, Insulation, Quantity and Capacity, Commercial Ampere and Voltmeters, Electric Power and its Measurement, Induction, Arc Lamps and their Mechanism, Continuous-Current Dynamos and Motors, Alternating-Current Dynamos, Transformers, Alternating-Current Motors, Conductors, Electric Transmission of Energy, Systems of Distribution, Central Stations. The lectures extend from January to December. The following are the conditions: The lectures will be given at the works, on Tuesday evenings, from 7.45 p.m. to 9 p.m.; the lectures will be open to all the articled apprentices of the firm, who will be expected to be regular and punctua in their attendance; all attending must provide themselves with a suitable note-book; questions may be asked at the close of each lecture, but they must refer only to the subject-matter of the lecture or previous ones.

Khotinsky Lamps.—M. D. Angé, of the Khotinsky Company, has published the result of some interesting experiments he has made on the relative advantage of different efficiencies of incandescent lamps. From these it would appear that it is not improbable in the future that lamps at 1·5 and 2 watts per candle might be used with economy. In the ordinary lamps 1·5 watts per candle will only give 55 hours' life, 2 watts 90 hours, and 2·5 watts 150 hours. But the following lives are guaranteed by the Khotinsky Company:

Initial consumption.	Average life.
1·5 watts per candle	250 hours.
2·0 " "	350 "
2·5 " "	500 "
3·0 " "	700 "
3·5 " "	1,000 "
4·0 " "	1,200 "
4·5 " "	1,500 "
5·0 " "	2,000 "

The Khotinsky Company have been able to obtain this relative long life in the lamps of 1½ and 2 watts per candle by the use of a "protector" to prevent the formation of the blue arc, which generally begins to show, when overrun, between the filaments. Consumers will wish to know if these figures can be maintained in practice, and in what degree the light falls off at the end of the time mentioned.

Electricity in Agriculture.—The employment of the artificial light of arc lamps for forcing plants and vegetables seems likely to be eventually adopted on a commercial scale, when the results of continued experiments that are being constantly carried out are made more widely known amongst those interested. The French are proverbially known as masters of careful husbandry on small plots, and in the direction of this *petite culture* by electric light they have already secured good results. Experiments have been carried on for some time back at the central markets, and the results have been communicated to the Académie des Sciences. The plants under observation were divided into three classes. One set was subjected continuously, night and day, to the full blaze of the electric light; the second set was kept alternately 12 hours under the artificial illumination and 12 hours in perfect darkness; while the third set was left for the purposes of comparison to the ordinary natural course of daylight and darkness alone. The conditions in regard to heat, moisture, and so forth were kept identical in all three categories. The result showed that the plants which were kept continuously under the electric light advanced in growth and retained their freshness in a very surprising manner, but their tissues were weak, flabby, and imperfectly developed. In the other two test cases, however, very little difference was observable between the sets of plants which had 12 hours' light and 12 hours' darkness, though the light in the one instance was natural and in the other artificial. The outcome of the experiment serves to show that plants thrive best with periods of alternating light and darkness, and that electric light for this purpose serves as well as the sun's rays.

Technical Schools.—Great activity is being manifested all over the country to give the full advantage of the technical education grants. A technical school was opened at Bath by the mayor last Friday, which is eventually to be housed in one of the new wings of the Guildhall. Mr. Day

is the director. At Ashton-under-Lyne new technical schools were opened this week at a cost of £16,000, of which £10,000 was given by the late Mr. G. Heginbottom The council includes representatives of most of the educational bodies in the town. A great feature is made of the chemical laboratory. The foundation for a new technical school for Salford was laid on Saturday, estimated to cost £50,000. Provision will be made for the teaching of physics, mechanics, engineering, and the handicrafts associated with it — joinery, turnery, wood working, plumbing, building construction, drawing, modelling, painting, spinning, weaving, dyeing, cookery, and some of the minor industries of the district. In the various class and lecture rooms there will be accommodation for 2,000 students. Commodious dining-rooms, dayrooms, and library will be provided for the use of the students, and suitable rooms for the teachers, committees, and secretaries. Behind the main building there is to be a large room, capable of seating about 600, for popular scientific lectures and entertainments, and for musical performances. At Stonehouse, the technical school has been enlarged and a large amount of scientific apparatus obtained, and tools and benches are being obtained. The Holland (Lincolnshire) County Council intend to appoint an administrative secretary, and active work is proceeding. At Richmond-on-Thames a new technical school will be erected, half-way up Richmond hill, on a new estate

Huddersfield.—The central station buildings at Huddersfield are not in nearly such a forward state as was hoped would be the case by this time of the year. A strike of masons intervened, and spoiled two of the best summer months. However, the masons are now at work again with a halfpenny out of the penny they struck for, and the buildings are gradually being brought into shape. The chimney shaft is half-way up, and the walls of boiler and dynamo houses are rising. Mr. A. B. Mountain, the Corporation electrical engineer, has his office in some old houses close by, and is doing his best to push things forward. The machinery has been ready at the Brush Company's works for some months. The mains also are mostly laid. The Callender Company have these in hand, and a new method of laying conduits has been used for the mains. Instead of solid bitumen jointed to form conduits, paper tubes are first laid in iron troughs and the melted bitumen is poured in solid around these tubes. This makes a very smooth and neat conduit, with no rough interstices, and the method is regarded as very successful. The station is only for a few thousand lamps at first, but it is expected by next winter an extension will be needed. No public lighting is to be done at present, at least, on any large scale, as the price of gas is so low, 10d. a 1,000 cubic feet, that it would cost three times the present charge for gas to light by electric light. A few arc lamps will, however, be placed in the squares, and at the intersections of the principal streets in the centre of the town. The central station, which is situated on Corporation land alongside the gas works, looks as if it were going to be a thoroughly satisfactory station, and the prospective demand is good, the Corporation having already wired the town offices, and the Huddersfield Technical College is to follow shortly.

Cables.—What kind of cable to specify and what insulation to use is a question which very often comes before consulting engineers and contractors, and as often as not is solved by specifying "Silvertown 600 megohm series, class S or K" for wire or cable as the case may be Of course if lead covered, for ship work, for high tension work, for concentric cables, other classes must be used, up to 5,000 megohms. For ship work it is still apparently doubtful how high a class should be used. One firm of good repute always uses 2,000-megohm conductors, and another equally good uses 800-megohm wires, maintaining that the leak in fittings is always too much for the difference in wire at 65 or 100 volts to make itself felt. However that may be, if wire is to be bought in England to-day, one certainly cannot go without the Silvertown catalogue, the subject of these remarks, a new edition of which is now before us. The list is divided into two parts—vulcanised and unvulcanised insulation. For ordinary installation work, the 300 and 600 megohm series are suitable, and can be highly recommended from long experience by most of our best electrical engineers. The Silvertown Company take immense pains to get the best results, all vulcanised wires and cables being subjected, in the course of manufacture, to a temperature considerably over 200deg F., and they can be relied upon to stand satisfactorily even at that temperature, an occasion which is rare enough. The conductors are all tested in water with an E.M.F of 500 volts after immersion at 60deg. F. for at least 24 hours, such long immersion and high-pressure test being sufficient to break down all incipient faults. A certificate of the test is given with every length of over 110 yards of the vulcanised wire and cables. This certificate should be attached—"See that you get it." The prices, number, size and weight of the Silvertown wires and cables are all fully given in the catalogue, No. 40 H, which no self-respecting electrical engineer of to-day can afford to be without.

Mill Lighting.—Mr. Jas. Gibson, electrical engineer, of Kilmarnock, has taken up our suggestion to furnish the *Belfast News Letter* with particulars and figures as to the cost of electric lighting. We abstract his figures as follows For isolated plant, dynamo driven by mill engine, the cost of a 500-light installation would be about £700; cost of upkeep, 5 per cent. interest and 5 per cent. depreciation, is ample. If driven from mill engine, the attendance is practically nil; cost of power should not be more than 3lb of coal per horse-power (of 10 lamps 16 c.p.); renewal of lamps lasting 1,200 hours is 3s. 9d. each. Assuming that 500 hours' lighting are required, we have interest £35, depreciation £35, coal at, say, 15s. per ton, £23, renewal of lamps £39—total, £132. The equivalent of gas would be considerably more. If the lighting hours are 1,000 per annum, the relative cost would be considerably reduced The longer the process, the more advantageous is the electric light. As to central station lighting, the prices charged by the various central stations throughout the country range from 8d. down to 4½d. per unit (are 16 c.p lamp for 16 hours), I believe, at Newcastle. The cost of fitting the light in private houses and shops runs from 25s per light. From the above it will be seen each 16-c.p. lamp costs fully ½d. per hour, even at 4½d. per unit. No one need expect to have the light from a central supply at the same price as gas in large towns at present, but its many advantages must more than compensate for its extra cost. Although its cost is greater, it will in many cases pay to use it, without considering its advantages from a sanitary point of view. All know the great havoc played by gas on the decorations of houses and shops, and many tradesmen find their goods considerably reduced in value from this cause The utility of the electric motor for tradesmen will also prove very considerable. Mr. Gibson's letter has been well received. Belfast is evidently anxious to have publicly and privately all information possible on the subject of the new illuminant.

Electro-Therapeutics.—It is perfectly evident that there is a definite intention on the part of the Medical Battery Company, or, as it is better known, Mr. Harness,

to fight to the bitter end for the value of his now widely-exploited electropathic belt. Our contemporary *Trade, Finance, and Recreation* seems to have taken up the cudgels on behalf of Mr. Harness. We believe, however, that such sentences as the following are unwarranted by any fact or facts that can be put forward. The sentence we refer to is as follows: "With regard to the currents generated by Mr. Harness's electropathic belts, they approximate closely in strength with natural currents, and as the belts may be joined up in any way which may be desired, they should, when intelligently arranged and applied, be productive of the most beneficial results." We cannot very well come to the final results of the author's experiments because they will not be known until next week, when the article is to be completed, but so far as we can gather from what we have before us there is nothing to connect the experiments, with an electropathic belt. In themselves, no doubt, the experiments described are exceedingly interesting. They seem to be directed to prove that the direction of current varies according to the amount of skin contact of the hand with the conductors attached to the galvanometer. For example, as described, the conductors attached to the galvanometers were composed of copper insulated with paraffin wax, and that the person experimented upon made contact on both plates with fingers and ball of thumb. In six cases out of seven a negative deflection was obtained. When, however, say, the ball of the thumb of the left hand was taken up, leaving contact only with the fingers, the deflection in six cases out of seven was positive. It would be interesting to know if the exception in each case is a left-handed man. Whether further experiments—or rather further consideration—by the author will not give a very simple explanation of these results, or if he will still contend "that the arms conduct as the two plates of a condenser conduct," must be left to the remainder of his paper; at any rate he has nowhere as yet given the slightest indication of how he connects his experimental results with any remedial efficacy of the electropathic belts.

Queensland.—On Wednesday a deputation of business men waited upon the Hon. W. Horatio Wilson to discuss the question of telegraph rates to Queensland. The deputation was very influential and put the whole question very fairly. Briefly it comes to this, that certain Australian colonies combined to guarantee the loss to the telegraph companies providing they reduced the rate per word. Queensland held aloof from this combination. We are a little indisposed to imagine, however, that the senders of messages have not been somewhat equal to the occasion. The tariff to Queensland is 9s. 5d. per word, while the tariff to the other Australian colonies is now but a little over 4s., and under the proposed fresh agreement will be 4s. 9d. We fancy that a large number of houses who have branches in Australia have branches elsewhere than in Queensland, and would telegraph their messages to the cheapest branch, and transmit by land. However, with this we have nothing to do. It is understood that if the agreement at the rate of 4s. 9d. per word comes into effect, the loss will be something like £8,000 per year under existing circumstances, so that if Queensland entered into the combination her part would be about £800. We have all along contended that the telegraph companies have by far the better part of this bargain, and that if they liked there would be no reason for any guarantee, and they could make an excellent thing out of it at even 4s. per word—or, at the outside, 4s. 6d. The tactics of the cable companies connected with Australia have been excellent from their point of view, and from the figures they provide not exorbitant. The position of the cable companies is easily defined. They have a certain capital upon which they want to pay dividends. Their working expenses must also be paid, cables maintained in efficient working order, and a sum annually laid by to replace cables when worn out; but, of course, business men have little or nothing to do with the *finesse* of Government and cable companies. What they look for is to obtain the cheapest possible rate, and if they thought they could do that by bringing pressure to bear upon the Government, they would bring pressure to bear upon the Government. If they thought they could do it by bringing pressure to bear upon the companies, they would bring pressure to bear upon the companies. From the remarks made by the Hon. W. H. Wilson, he seemed to think that the deputation made out a very strong case, and promised to communicate with his colleagues the views that had been expressed, and to do everything in his power to further the object in view.

Overhead Conductor Tramways.—One of the most successful electric railways in America is that between St. Paul and Minneapolis. These two rival towns, numbering each about 350,000 inhabitants, are situated about 10 miles apart. There are, in all, about 217 miles of tramway in the two cities, and a car runs between them every six minutes, giving a splendid service, always crowded, all day and night, save in the morning from 2 to 5 a.m. The fare is 2½d. in each city, and fivepence between the towns. The speed is from five to eight miles an hour along the streets, and up to 15 miles an hour in the open. The whole of the system is worked by overhead conductors by electricity, except 20 miles of cable in St. Paul's shortly to be changed. The gradients are severe, several of 1 in 20 and a few of 1 in 12½. A correspondent of the *Scotsman* who has recently visited this system of electric street railways, says: "I stated publicly some months ago that the overhead system was the only one now practicable. Others who had, no doubt, means of information far superior to those at my disposal scoffed at the assertion. The persons at the head of the business here assure me that the day is far distant when practically any other system of electrical propulsion of street cars will be possible. The loss in storing electricity in accumulators is excessive. The difficulty of conducting the necessary current underground is almost insuperable. The ugliness of the overhead system is, in my opinion, very much exaggerated. It is no uglier to our eyes than the rows of street lamps were to the eyes of our forefathers, who deplored the picturesque effect of the hanging lanterns so convenient and accessible in 1790. Here the lighting and the tramways are separate properties, and if they were not, the central pillars would be utilised for the electric lamps, and the effect would be just the same as in the boulevards at Paris. The rate of five cents is considered cheap here. I think it is dear. The wages of the men employed is about 17 cents per hour. They work generally 12 hours. The work is not heavy. With us we should require to have a zone system based on a uniform penny rate, with as wide a zone as possible. If we want a rapid, safe, cleanly, and cheap system of tramway accommodation in Edinburgh extending to places like Roslin, Queensferry, Dalkeith, we must be content to accept it with its attendant drawbacks. If we prefer to let posterity enjoy the advantages, we shall wait for accumulators to save the disfigurement of such lovely scenery as abounds in Leith-walk and the bridges. In places like Princes'-street it would be possible at some sacrifice to convey the wires underground."

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

(Continued from page 327.)

III.—WORK AND HORSE-POWER.

It may not be out of place to make a few remarks and give some practical examples respecting Energy, Force, Power, and Work. These four terms are often used synonymously and applied in a loose manner.

Force may be defined as "that which moves or tends to move matter." When a mass of matter is lying at rest it requires some force to start it, or to overcome its resistance to motion, this resistance to motion is called the inertia of the mass. The weight of a mass of matter is merely the force of gravity acting on it, so if you hold a stone in your hand its weight signifies that the gravitating force of the earth is pulling at the stone, striving to drag it down to the centre of the earth, and the muscular force you have to exert is spent in balancing the force of gravity. The greater the mass is, the greater is the force of gravitation acting on it, consequently its weight is greater. If there were no such thing as gravity, matter would have no weight, and, owing to the enormous centrifugal force due to the revolution of the earth, everything on its surface would tend to fly off into space.

Every particle or mass of matter exerts an attractive force upon every other particle or mass of matter, so that two bodies have a mutual attraction. The amount of attraction a body possesses is in proportion to its mass, and the mutual attraction of two bodies is in inverse proportion to the square of the distance between them—that is to say, two bodies 6in. apart are attracted to each other by four times the force by which they are attracted when at 12in. apart. We have every reason to believe that this law holds true in our planetary system, and throughout interstellar space. It is due probably to this theory that the earth is kept at a definite distance from the sun when revolving round it, and that all the planets have their fixed course. So when a mass of lead falls to the earth it signifies that the lead and the earth, following the law of mutual attraction, attract each other with a force proportional to their size, and inversely proportional to the square of the distance between them; but since the mass of the lead weight is infinitesimal as compared with that of the earth, therefore it follows that the force the lead exerts is comparatively nothing to the force the earth exerts, and the result is the lead travels all the distance, and the earth so little that it cannot be perceived.

Fundamental Units.—The French system of measuring quantities is the most simple and beautiful invention that can be imagined. It is greatly to be regretted that this method of measurement is not adopted in England by practical engineers, and that it is not used in workshop practice here. In no branch of science can it be appreciated so much as in that relating to electricity and magnetism. The British workman still plods on, using the clumsy and unscientific foot and pound, whose use causes a vast amount of brain work and valuable time to be wasted, when both could be saved were they to think and make calculations in the French units. Taking the one example of length. The foot is the British unit of length for engineers, other dimensions are the mile, yard, etc. To express miles in inches, your practical man has to multiply out on a piece of paper the expression $1,760 \times 3 \times 12$. Now examine the French unit of length—namely, the "metre"—this corresponds to the English yard, its equivalent being 39·39in., or nearly $\frac{1}{10}$th more than the yard. For great lengths, the French use the "kilometre," or 1,000 metres, and so this may be said to correspond with the mile, whilst for short measurements they have the "centimetre," or $\frac{1}{100}$th part of a metre, and this corresponds to the inch, there being 2·54 centimetres in 1in., or one centimetre = $\frac{2}{5}$in. From this it is seen that all dimensions of length are expressed in multiples of the figure 10. Thus a kilometre is reduced to centimetres by multiplying by 100,000, because there are 1,000 metres in the kilometre, and 100 centimetres in one metre. 100,000 can, however, be written in a much simpler and quicker manner by expressing the number in powers of 10, thus 10 can be written 10^1, because there is only one 10, and 100 can be written 10^2, because it signifies two tens multiplied together, or 10×10, similarly $1,000 = 10^3$, and $100,000 = 10^5$, so that one kilometre can be expressed in centimetres by the simple expression 10^5. It is the same with the units of weight. The British units are tons, hundredweights, stones, quarters, pounds, ounces, pennyweights, grains—an array sufficient to drive anyone to despair. Who does not remember the mental torture of committing to memory those weights and measures tables of our juvenile school days? To express tons in ounces, we must multiply out the lengthy expression of $20 \times 112 \times 16$. The French unit of weight is the "gramme," and 454½ grammes go to the English pound. The kilogramme signifies 1,000 grammes, and corresponds to the pound, its value being 2·2lb. The milligramme signifies $\frac{1}{1000}$th part of a gramme, and all these weights are expressed in multiples of 10, same as with the various lengths. One kilogramme = 1,000,000 milligrammes, or 10 milligrammes. The above instances are only two out of a number that could be quoted to prove how barbarous and ridiculous our units of measurement are. Knowledge is quite hard enough to acquire without making its acquirement doubly laborious, units and standards are merely arbitrary and used as vehicles to convey our thoughts in drawing comparisons, and they should be the slaves of man instead of man being their slave, as he often is.

Length, Weight, and Time are the three fundamental quantities, and in the French system the centimetre is taken as the unit of length, the gramme as the unit of weight, and the second as the unit of time—the symbol letters C G S being used to denote respectively the centimetre, the gramme, and the second. Hence the system is known universally amongst scientists as the C G S system of absolute units. Unfortunately, this system is so little known in England that it would perhaps be better to express mechanical calculations in foot pounds, since these units are known to everyone, whilst the others are only known to a few.

The Unit of Force is named the "dyne," and it is that amount of force which acting for one second, when applied to a mass of one gramme weight, will move it through a distance of one centimetre in one second of time. This force is expended in overcoming the resisting force of the mass through a distance, and when this is effected, it is said that *work is done* upon the mass. When a mass is lifted up vertically, work is done upon or absorbed by the mass, since the resisting force of gravity is overcome through a certain distance.

The Unit of Work is named the "erg," and it signifies the work done in overcoming a resisting force of one dyne through a distance of one centimetre. Now if a mass of matter weighing one gramme be allowed to fall freely, it would be seen that, owing to the force of gravity acting upon it, it would fall a distance of 981 centimetres in one second of time, hence the force of gravity equals 981 dynes, so when one gramme of matter is lifted vertically through a distance of one centimetre it is evident that a force of 981 dyne must be overcome through a distance of one centimetre; consequently, 981 units of work must be spent on the mass to raise it that distance.

Energy is an expression that denotes the capability of a body to do work. All moving bodies possess energy, usually termed stored energy, thus, a moving railway train has a vast amount of stored energy in it, and so has a revolving wheel. It has been shown that an expenditure of 981 ergs is necessary to raise one gramme through a vertical distance of one centimetre. It may be thought that this amount of energy is wasted, but this is not so, for we have the law of the conservation of energy to deal with, and the energy is absorbed by the weight and can be recovered, for let the weight fall back to its original position, in the act of falling it will develop energy, and do work, and the work done by it will be exactly equal to the work done upon it; so that a body can have two kinds of stored energy in it, one kind when in motion and the other kind when at rest. All

bodies at rest possess "potential energy," in virtue of the position they occupy, as compared with bodies at a lower level. A boulder on the top of a lofty mountain possesses a great amount of potential energy because falling to the plains below it could develop, by virtue of its elevated position, great energy. A boulder on the plains possesses an amount of potential energy measurable by the distance it can fall. From this it can be understood that the potential energy of a body decreases as it gets nearer to the centre of the earth, and if it were possible for a body to be situated exactly in the centre its potential energy would be zero. Kinetic energy, on the other hand, is the energy that is developed by the moving or falling body. A stone just at the moment of falling possesses nothing but potential energy, so that its potential energy is a maximum and its kinetic energy a minimum, or zero; whilst falling, the potential energy changes into kinetic, half-way down its energy is half potential and half kinetic, and at the moment of striking the ground its kinetic energy, or developed capability of doing work, is a maximum, while its potential energy is at zero, the potential thus becoming converted entirely into kinetic (so far as concerns the potential energy due to the difference between the two levels).

Work can be expressed as the product of two factors, weight and distance; and however the values of the factors change, provided the product is the same, the work done is the same. Thus, 50 grammes raised 100 centimetres requires as much work as 100 grammes raised 50 centimetres, or 1,000 grammes raised five centimetres.

Power means the rate of doing work or the amount of work that can be done in a certain time.

The unit of power is named the "watt," and signifies work done at the rate of 10,000,000 ergs per second; this is the practical unit, because the absolute unit of power, which signifies one erg per second, is far too small to be of any practical value. It was shown that it required 981 ergs to raise one gramme a distance of one centimetre, and as one watt equals 10,000,000, or 10^7 ergs per second, therefore (using 1,000 for 981 for simplicity) it will raise $\frac{10^7}{10^3} = 10^4$ grammes a distance of one centimetre in one second, or 10 kilogrammes a distance of one centimetre.

One kilogramme equals 2·2 English pounds.
One centimetre ,, ·4in. (nearly).

and 2·2lb. raised ·4in. is equivalent to nearly ¾lb. raised 1ft. high. So in English units one watt signifies work done at the rate of lifting ¾lb. a distance of 1ft. in one second (approximately).

The watt is adopted as the unit of electrical power, and will be further considered in this respect when treating of electrical units. For mechanical powers the unit of power in England is the horse-power; and expressed in units of pounds, feet, and minutes, it is equivalent to 33,000lb. raised 1ft. in a space of one minute—that is, 33,000 foot-pounds per minute; and this number was fixed upon because it was reckoned that a very strong dray-horse could do that work, but if it could, it could only keep up this rate of work for a very short time, say, a few minutes, so that the average power of a good horse, working all day, is far less than the standard given, in all probability not much more than 20,000 foot-pounds per minute. 33,000 foot-pounds per minute = 550 foot-pounds per second, and 550 ÷ ·737 = 746, so that 746 watts go to the horse-power.

There are three different kinds of horse-power used when expressing the power of a steam engine: Nominal, Indicated, and Brake. Concerning the first—namely, that of nominal the less said the better, the word is simply used by makers of steam engines and boilers to express size, and gives no information respecting the power of a machine. Some makers say that their nominal can be taken to signify 2½ times the indicated, others three times; others, again, twice; others still something else. It is a wretched term, absolutely useless, and a cause of considerable annoyance; an undefined term like this always has a suspicious appearance. The disease, unfortunately, has seized hold of electrical apparatus; thus we have arc lamps of *nominal* candle-power, and the trusting purchaser either finds out, or does not find out (according to his knowledge or ignorance) that the actual candle-power is probably one-half of the nominal. The word "nominal," when applied in this misleading way is deceptive in the sight of every right-minded engineer.

Indicated horse-power signifies the rate of work done by the piston, and so is a measure of the power developed by the engine. Brake horse-power signifies the power that is given right off the driving wheel, and evidently this measure is the best and fairest, because it represents the actual useful power given by the engine. The brake is necessarily less than the indicated, since the difference between the two measures the loss due to the friction, etc., of the moving parts, and this loss differs a great deal in various engines, according to whether they are well designed or not; it also differs according to the size of the engine. For example, a large sized engine may have its brake 12 per cent. lower than its indicated, while in small engines it may be 20 per cent. or more.

How to Calculate Indicated Horse-power.—This is done in the following way. Multiply the pressure of steam in pounds per square inch by the area of the piston in square inches; this gives the total force acting on the piston. Now multiply this by the distance in feet through which the piston moves, or the length of stroke, as it is termed, but since the piston must make a forward and backward stroke in order to produce one complete revolution of the driving wheel, hence the length in feet must be multiplied by 2. We have now obtained the product of a force acting through a distance, which signifies work done in foot-pounds; and to obtain the power, or rate of doing work, we must finally multiply by the number of revolutions per minute that the driving wheel makes. This gives the number of foot-pounds moved in the space of one minute, and when the rate of doing work is such that 33,000 foot-pounds of work are done in one minute, then 1 h.p. is produced, so we have now to divide the total product by 33,000. The result gives the horse-power.

This rule may be expressed in the following formula:

$$\frac{P\,L\,A\,N}{33{,}000} = 1 \text{ h.p.}$$

P = pressure of steam in pounds per square inch.
L = length of stroke of the piston in feet, multiplied by 2.
A = area of the piston in square inches.
N = number of revolutions per minute of driving wheel.

Here the three fundamental units of weight, length, and time are represented.

1. Pressure representing the weight in pounds.
2. Stroke ,, ,, length in feet.
3. Revolutions ,, ,, time in minutes.

The following example shows how to apply the above: The cylinder of a simple engine is 9in. in diameter, its length 12in., speed is 200 revolutions per minute, and steam pressure 80lb. per square inch. Find its indicated horse-power.

ON THE MANUFACTURE OF INCANDESCENT ELECTRIC LAMPS.

BY FREDERICK GRAHAM ANSELL, F.C.S.

(Concluded from page 328.)

I have now described a complete process for making an electric incandescent lamp, and have in one or two instances given a brief outline of an alternative process for doing certain parts of the work, but there are several other matters which should also be mentioned, consequently I add this appendix, although what I have previously said should be ample to enable anyone with a little knowledge of electricity to make a complete lamp.

In the first place, I must mention that several dipping solutions have been tried and patented, but none of them are improvements upon the sulphuric acid solution mentioned in the text. There is a beautiful blue solution

known as cuprum ammoniatum, or ammoniated copper, made either by adding strong liquid ammonia to a concentrated solution of sulphate of copper, or by standing bright copper turnings in strong ammonia solution. This solution is used by the Willesden Paper Company in preparing their valuable papers for various purposes. It gives very good results. There was also a patent for preparing the filaments by means of a strong acid solution of sulphate of zinc. All I know of this is that the lamps supposed to be made by it are never heard of now. With regard to Swan's patent for preparing filaments by dissolving gun cotton in ether, etc., as mentioned in the early part of the text, it appears to me that the chief advantage to be derived from this is that the cross-section of the filament may be made any desired shape, while at the same time its homogeneity is assured. The shape of the cross-section is not altogether a matter of indifference in designing a filament, because, although a circular form gives the greatest mechanical strength, it at the same time encloses the greatest amount of material in the smallest possible surface; and as only the surface emits light, although the whole mass has to be raised to incandescence, it necessarily follows that with a round-section filament we are doing maximum work to obtain minimum light, because if we could flatten the filament we should have much more of its substance exposed, or, in other words, we should get more luminous surface but at the expense of mechanical strength. It is also possible to flatten cotton prepared by the sulphuric acid process a little, but not to anything like the extent possible in Swan's process. I need hardly mention that the length of the filament is not a matter of indifference in designing a lamp, as, other conditions remaining equal, the longer the filament the greater the candle-power of the lamp. The only way to ascertain the amount of light given by a lamp (its candle-power) is by a photometer, and the simplest and easiest of these is perhaps that known as Bunsen's. It consists of a straight horizontal rod about 12ft. long, graduated in inches, with the usual smaller fractional parts, such as the quarter or one-eighth, accurately marked. At one end of the rod is a candle burning 120 grains of wax per hour, and with a nice, small, evenly plaited wick, while at the other end is the electric lamp burning under its proper conditions. Between the two is a light movable frame capable of standing by means of clamps or feet on the graduated rod, and holding vertically a sheet of clean white note-paper, or white tissue-paper evenly extended, so that its surfaces shall be at right angles to the rays of light coming from the candle, and also to those coming from the electric lamp. In the middle of the paper a spot of grease—say, oil—is put; this is best done before the paper is mounted in its frame, as then it can be held horizontally and a drop of oil allowed to fall on to it. To use this instrument, the frame and its paper is moved along the rod in the required direction until it is no longer possible to discern the grease spot. The distance between the paper and the candle is accurately noted, also that between the paper and the lamp—each distance is multiplied by itself, or squared, as mathematicians say, and the smaller divided into the larger, when the quotient is the candle power of the lamp.

Next, as to the "paste" used for fastening the filament to the platinum leading-in wires. Distilled water should be used in mixing this, because ordinary water contains lime and other chemical bodies, such as carbonates and sulphates, which are easily decomposed by contact with hot carbon, and which contain oxygen, the worst enemy of the filament; in fact, the only object of the elaborate and troublesome process of exhausting the air from the globe is to keep oxygen from the filament, because oxygen has the power of combining with carbon and converting it into invisible, but poisonous, gases—namely, carbonic acid and carbonic oxide. Further, the decomposition of the chemical salts contained in the water would also tend to disintegrate the filament, besides effecting the destruction of it as above, but I need not trouble you with chemical formulæ, as it is sufficient to say that the carbon should be kept as pure as possible, and that no amount of exhaustion by the air pump could possibly get the combined oxygen from any of the salts contained in water.

The drying chamber, D, of the air pump, Fig. 6, may contain concentrated sulphuric acid with a few small lumps of pumice stone, or powdered anhydrous phosphoric acid, or fused chlorides of calcium; but this chamber is really more trouble than it is worth, so I should dispense with it entirely, more especially as I have found by experience that there is no great need of it. While on the subject of the air pump I will just mention that there appears to be no reason why it should not be made of iron throughout, provided that the inside of every tube should be quite smooth, like a gun barrel. The joints could be made perfectly airtight with very little trouble and the use of red lead, and a piece of glass tube could be put in for a gauge, to show how the vacuum is if thought advisable, and also a piece of glass tube could be joined on perfectly airtight from C to K, so that the lamps might still be put on for exhaustion, as already suggested. With those iron tubes a gauge glass parallel with G G would certainly be desirable. The great advantage of the iron pump would be its superior strength, for, as already stated, the glass tubes are constantly breaking, and this in a large factory becomes a serious nuisance. Whether made of glass or iron, the pump should be carefully attached to a piece of board to keep it in its proper shape and position, for the weight of the mercury in the various parts when the pump is at work is very considerable. So far as at present described, the pump, Fig. 6, should be terminated at K, but as the exhaustion is rather a long operation, it might be advisable to use some form of quick acting mechanical pump to obtain a fair vacuum of, say, about 28in. of mercury to start with; and if this were done, some such arrangement as that depicted at K M N would be necessary, N being a small movable cistern attached to the U tube, K M, by means of a flexible indiarubber tube, as shown at A B C D in Fig. 5. The mechanical arrangement would then be connected at M.

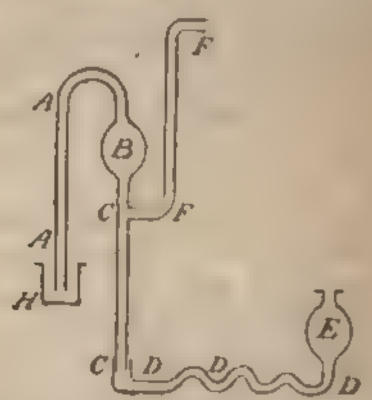

FIG. 7.

Instead, however, of a plunger or mechanical air pump, there is another form of mercurial air pump which is very simple, fairly expeditious, and easily managed. It was used by Lane Fox in his early experiments, and is capable of giving a good vacuum of 30in., whereas a plunger air pump will not give more than 28in. The pump is best made as in Fig. 7, where A is a tube bent over, as shown, and dropping down at least 33in. or 36in. into a vessel of mercury, H, where the air escapes; B is a somewhat capacious vessel between the tubes A and C. At the bottom of C is a flexible tube leading to a cistern, E, which can be raised and lowered at will. The vessel to be exhausted is attached to the upper end of the tube, F, which must be at least 33in. in length in its vertical part.

The vessel, E, must always be raised gently, or else the mercury will run over the top of F when the vacuum becomes good. All corners should be avoided in the tubes A, C, and F, as also in the vessel, B. This pump may be made of glass, or smooth-bore iron tube. It is well, in arranging both this and Sprengel's air pump, Fig. 6, to arrange the lamp, or any vessel to be exhausted, so that the air it contains at starting may be able to fall or flow out easily, and not to connect it to the pump, so that its contained air must pass out at the top, for in the latter case a perfect vacuum becomes an impossibility.

The principal object in "flashing" is to make the sectional area of the carbon filament uniform throughout its

entire length, as any part being thinner than the rest would, of course, become hotter under the action of the electric current, and it would therefore get a more abundant deposition of carbon from the benzene or gas, as the case may be, whilst any thicker parts being cooler would not get so much in the same time. Consequently the filament, if uneven before flashing, is even after. Flashing also coats the filament with a hard, compact form of carbon, and makes it more durable and more efficient. It is often found that the resistance of the finished lamp is not quite identical with that of the filament at flashing. The filament should never be flashed in its own bulb or globe, but always in a somewhat larger vessel, as suggested in Fig. 4, because the decomposition of the hydrocarbon vapour produces a heavy, oily substance which coats the inside of the flashing vessel and would obstruct the light, thus reducing the efficiency of the finished lamp. Glass is suggested in Fig. 4 to enable the action to be easily observed and understood, but in actual practice an iron vessel would be preferable, and it should be arranged to screw on to its place or bottom plate perfectly airtight. If it is made simply to lie on a plate as an ordinary air-pump receiver, difficulty will be found in removing it after each operation, and this will lead to the breakage of many filaments, unless special protecting studs could be used.

It has been suggested that certain refractory bodies might be incorporated in the carbon of the filament made by Swan's process of dissolved nitro-cellulose, etc., but owing to the danger of chemical reaction between these bodies and the white-hot carbon, and also owing to the unequal expansion and contraction they would cause in the filament when lit and extinguished, this idea had to be entirely abandoned in favour of the purest carbon which can be obtained.

It is worthy of note that the resistance of a filament cold is about double its resistance when hot, and that the work required per candle-power is about four watts for 16 or 20 candle lamps. This figure, however, does not hold good for lamps of much larger or of much smaller candle-power, nor is it exactly true for lamps which are not well designed, or for lamps of low resistance, which require a large current. For instance, a lamp designed for 100 volts would require about ·62 ampere, while a lamp designed for, say, 50 volts, would require about 1·4 amperes. All incandescent lamps are very delicate, and consequently require great care from the person in charge of them. If subjected to a higher E.M.F than that for which they are made, their endurance will be greatly shortened, but under favourable circumstances they should give a good light about 1,000 hours. The author has, however, known several 16-candle Swan lamps to last 1,700 hours on an installation under his own charge. Some makers have claimed a higher efficiency than four watts per candle power, but this must not be too readily credited, as it is a matter of some difficulty to determine the exact candle-power of a lamp. In fact, at one time it was a custom to send out 16-candle lamps as "20-candle lamps"; and in making the test it would be very easy to claim almost any efficiency, because the amount of light emitted varies at a very rapid rate with the current when the current is anywhere the normal figure. The lamp would withstand this strain long enough to give most flattering figures, but if always subjected to the same current the strain would be too great, and so the lamp would not stand the time test, and its real efficiency would be reduced to absurdity. Mr. Preece, the electrician to the Post Office, found that the light given by a 16 candle lamp varies with the sixth power of the current when normally lit.

This treatise would hardly be complete if I omitted mention of a plan I devised in 1883 for making a then new form of filament, and which formed the subject of an agreement between a well-known electrical firm and myself. I proposed to take a wire or strip of, say, calcium, or one of the metals of the same group, and to oxidise its surface by passing a current through it just enough to make it hot. This would coat it in the case of calcium with a covering of lime, which I thought would be strong enough to keep the metallic strip or thread in its interior intact, but of course there was a doubt on this point, and a break in the continuity of the unoxidised metal would have been fatal to the lamp. It is also very possible that expansion and contraction would have been too much for my compound filament, and so the scheme was abandoned, as also one I had for coating an ordinary carbon filament with an electro-deposition of the same metal (calcium) or aluminium, or magnesium, and then oxidising it entirely; but except as a matter of history these designs are not worth mention, as they have all been abandoned in favour of pure carbon. In conclusion, a plea for our native language. Let me ask you always to say incandescent lamps, because this is more in accord with the idiom of our tongue than incandescence lamps or glow lamps.

TRANSFORMERS MADE BY THE SOCIETE L'ECLAIRAGE ELECTRIQUE.*

BY M. F. GERALDY.

The theory of alternate-current apparatus is settled satisfactorily, but the methods of calculation applied to these machines in practice are less understood than for continuous currents. The makers have their rules, but these are hardly as yet definitely embodied in practical formulæ. With regard to resistances and the heating of wires these calculations are based on what is known of continuous currents, but as regards inductive action, the preponderating effect in alternate-current apparatus, progress seems still largely to be made by the method of trial and error.

This absence of calculation produces the risk of serious errors in any departures from old forms, witness the Frankfort experiments, where the machines, built for 300 h.p., did not transmit over 120 h p.; the designers did not sufficiently allow for self-induction. Other examples might be easily given of apparatus built for certain purposes which has had to be abandoned for want of the proper facility for theoretical calculation beforehand. This uncertainty was less troublesome for generators—in some cases it was even useful. The Gramme alternator by chance gave a constant current, and thus was exactly the most favourable for driving Jablochkoff candles, for which purpose it was designed. But the disadvantages became fully apparent when alternators began to be employed as motors.

The necessity for a complete theory is making itself widely felt, and it is certain, moreover, that we shall not need to wait long. This theory is crystallising itself; we shall have only to bring together the partial studies already made to obtain a satisfactory whole.

What is true of the alternate-current dynamo is true of the transformer. We have no correct working theory known by all. We can doubtless easily give the principles of its action, but the theory so presented is only figurative, and gives little real guide in construction. On the other hand, we can establish mathematically and with exactitude the theory of the apparatus, but the theory is complicated, and it is difficult to discover therein a basis of application. Added to this is the fact that, from want of sufficient well-designed machines, we do not as yet possess the experimental data necessary for the construction of suitable apparatus for predetermined output and the best use of materials.

In the first attempts at transformer building theoretical ideas, correct in themselves, were taken, and the greatest effort was made to utilise to the utmost the mutual induction of primary and secondary circuits. With this object, Gaulard intimately mixed the circuits together, and Zipernowski enclosed his transformers in a covering of iron. It was at this period that arose the quarrel between open and closed magnetic circuits—a quarrel which is even now not completely ended. This continuance of the discussion is alone sufficient to prove that the theory of transformers is incompletely settled, for a question of this kind should be at once determined. The closed magnetic circuit seems to be the one now generally adopted, and it appears certain that the truth is in this direction: theory will eventually confirm practice.

* Translated from *Electricité*, September 15, 1892.

But in striving to fulfil the theoretical considerations, sufficient attention has not been paid to those practical considerations, the importance of which will make themselves felt in actual use. It has been easy to arrange the circuits from the point of view of resistance and heating, for it was here that the habitual calculations aided, but sufficient attention has not been paid to the heating of the iron by hysteresis, which is very considerable; on the other hand, the close juxtaposition of the two circuits at very different potentials soon showed itself to be a danger to insulation and a great difficulty in construction. The first types of transformers are therefore becoming greatly modified.

The efficiency of transformers was not difficult to calculate for normal working—that is, for full load; but it was necessary to remember that this efficiency fell considerably as the load diminished. This lowering of the efficiency at small loads is even to-day the principal defect of transformers. It has proved so serious that it has brought about an entire change of system; instead of distributing, as seemed natural and easy, as at first was done, by arranging small transformers at every point of distribution, so as to distribute entirely at high tension, the tendency is nowadays, on the contrary, to erect a small number of transformer stations and distribute at low pressure; and even in these stations means are taken, either automatic or by hand, to regulate the transformers. All this causes, for alternate-current systems, a noticeable increase of expense, and introduces serious complication.

This defect of the transformers is so general that it is willingly considered as inherent to the apparatus. If it is maintained that the efficiency will always be lower as the load decreases, this is no doubt true. But what is not true is the statement that this defect will always bring with it, for high-tension distribution, the disadvantages that have been mentioned; it is simply a question of proportion.

If the efficiency, for instance, fell from 95 per cent. at full load to 60 per cent. at quarter load, the defect is serious; if the efficiency fell only to 75 per cent., the defect is less grave; while if the lower limit was 85 per cent., it is practically insignificant. Call to mind what has happened in the construction of dynamos. At first a number of different arrangements were made to regulate the efficiency of dynamos; their voltage varied greatly with the load. The method of double winding was invented specially to correct this defect; yet nowadays it is hardly used save in certain particular cases. The machines have become so good that their loss of efficiency plays but an insignificant part.

Cannot the same result be obtained by a good construction of transformers? The figures communicated to us, which we give further on in this article, seem to show that it can.

The Société L'Eclairage Electrique, which owns the Jablochkoff candle in France, have always needed to produce and distribute alternate currents. It was natural, therefore, that they should busy themselves with the manufacture of transformers. They have established a very complete factory for this purpose, and produce three different types of transformer. The first, Fig. 1, employed for low pressures, was designed for use with the Jablochkoff candle. The magnetic circuit presents the form of a rectangle. The base is formed of plates of insulated sheet iron, the extremities of which are slotted. On this part are wound the primary and secondary bobbins, which are distinct and superposed. The circuit is closed by means of sheet iron plates curved in horseshoe shape, and introduced and punched in place in the slots prepared in the base. These small transformers can transform from 500 to about 1,000 watts. When used with Jablochkoff arc lamps they are employed one for each lamp, the distribution being generally in series on a single cable. The Gramme alternator, which has a practically constant current, lends itself well to this very convenient arrangement.

The second series goes from 1,000 to 5,000 watts; the transformers are similar to those of the third type, and it is therefore not necessary to describe them. We ought, however, to point out one detail which is, indeed, general in the transformers of the Société L'Eclairage Electrique, and is considered very important. The superposed sheets of insulated iron which form the magnetic core are not all of the same width. They are put together by successive layers of slightly different widths, as seen in Fig. 2. This arrangement establishes along the core a series of longitudinal slots, which, when the transformer is working, act as air passages, allowing the iron core to cool. This special cooling of the core is, it seems, of the greatest utility, and, as will be seen further on, still other means have been sought to obtain this cooling effect, which allows the mass of iron to be reduced, and the maximum of permeability to be employed—one of the most important elements in efficiency.

FIG. 1.

Fig. 3 shows the construction of the iron for the third series. The sheet iron is cut in rectangles and the pile is put together with cooling surfaces; from this mass a solid cylinder is cut out, as shown, leaving the legs much in the shape of dynamo magnets. On these legs are placed the primary and secondary windings, always distant and superposed, and then the cylinder is replaced, completing the magnetic circuit in a very satisfactory manner.

Still further to ensure the cooling of the iron, transformers have lately been constructed with small spaces between the core and the coils, forming air shafts in which the air circulates energetically. It has been found that in the transformers thus built a considerable difference is established during working between the temperature of the core and of the wire and their insulation, the latter remain comparatively cool, a result which ensures good preservation.

FIGS. 2 AND 3.

The transformer thus built up is drawn together tightly by means of bolted cast-iron frames, which serve at the same time as feet. The transformer then presents the appearance shown in Figs. 4 and 5.

The commercial transformers are not furnished with the numerous terminals shown in the illustrations, which represent combination transformers, constructed for the study of high pressures. These were constructed specially for the researches which are being made by M. Leblanc for the Société pour la Transmission de la Force.

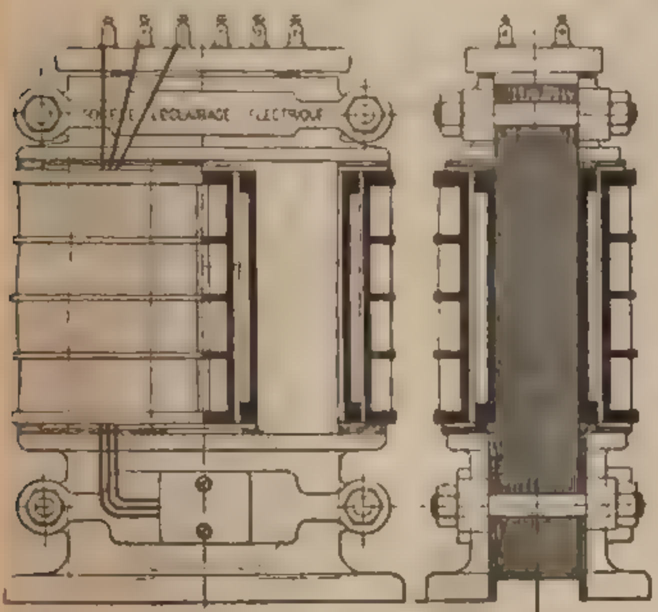
The following are the details of these transformers, furnished by the Société L'Eclairage Electrique. We take as a sample of the commercial transformers one of 15,000 watts.

The secondary circuit can generally be modified by a certain number of turns in order to obtain the exact

E.M.F. required for the mains. This model may therefore be employed for 2,400 or 2,500 volts primary, and the pressure of distributing wires can be regulated for 100 or 105 volts.

Section of primary circuit	4·52 sq. mm.
Effective strength of current, about	6·25 amp.
Density of current per sq. mm., about	1·38 amp.
Number of primary turns	720
Resistance of primary	2 ohms.
Loss of E.M.F. in work	
$r_1 i_1 = 2 \times 6{\cdot}25 = 12{\cdot}5$	½ per cent., about.
Section of iron	130 sq. cm.
Effective E.M.F. of primary	2,400 volts.
Frequency	80
Effective induction B per sq. cm.	4,440
Maximum induction	6,250
Section of secondary circuit, several wires in parallel	133 sq. mm.
Effective secondary current	150 amp.
Density of secondary current	1·13 per sq. mm.
Resistance of circuit	0·00333 ohm.
Loss of E.M.F. in work	
$r_2 i_2 = 0{\cdot}00333 \times 150 = 0{\cdot}0499$ volt, or	½ per cent.
Weight of transformer, 225 kilog.	495lb.

The variation of E.M.F. between no load and full load for a constant primary E.M.F. is about 1 per cent.



Figs. 4 and 5.

The efficiency is taken at the mean temperature of working:

88 per cent. at	⅛ full load.
90 ,,	¼ ,,
92 ,,	⅓ ,,
94 ,,	½ ,,
96 ,,	¾ ,,
97 ,,	full load.

The efficiency decreases a little after a very prolonged run at full load by reason of the heating of the copper, but as the arrangement described renders the temperature of the wire practically independent of the temperature of the iron, the transformer keeps very high values of efficiency at small loads.

The loss in running at no load is less than 2 per cent. of the total power absorbed at full load.

It will be interesting to mention the manner of testing the efficiencies. A method similar to that indicated by Hopkinson for dynamos is applied. Two similar transformers are connected up to act against each other, and the total efficiency is measured after the double transformation. The number obtained is the square of the number sought. Measurements made thus at low pressure and on quantities of the same order are easier to take and are more precise.

Special transformers have been constructed, as we have said, for the researches of MM. Lublanc et Hutin. The following are the data given of some of these transformers.

The transformers are of 5,000 watts at a frequency of 80, the effective E.M.F. being 30,000 volts. Both primary and secondary circuits are wound in sections. The following figures are with the primaries all in series, and the secondaries all in parallel:

Section of primary circuit	0·1257 sq. mm.
Current, about	0·166 amp.
Density of current	1·33 per sq. mm.
Number of turns in primary	14,470
Resistance	1,248 ohms
Loss of E.M.F. in work	
$r_1 i_1 = 0{\cdot}166 \times 1{,}248 = 207{\cdot}9$ volts, or	less than 1 per cent.
Section of iron	72 sq. cm.
Effective primary E.M.F.	30,000 volts.
Frequency	80
Effective induction per sq. cm. B	5,740
Maximum induction	8,100
Section of secondary circuit, 12,566 × 2 =	25·13 sq. mm.
Effective current	27·5 amp.
Density of current per sq. mm.	1·095 amp.
Resistance of circuit	0·026 ohm.
Loss of E.M.F. in work,	
$r_2 i_2 = 27{\cdot}5 \times 0{\cdot}026 = 0{\cdot}715$	less than ½ per cent.
Secondary E.M.F.	182 volts
Variation of E.M.F. between full and no load	about 1 per cent.

The efficiency of this transformer at full load is about 95 per cent., and at the lower load it maintains the high efficiencies of the previously mentioned transformers.

Amongst other commercial transformers constructed by the company for primary currents of very high pressure, we may notice the following, which present the principal characteristics of the other transformers.

6,000 watts, frequency 70, primary 10,000 watts.
4,000 ,, ,, 43, ,, 25,000 ,,

All these high tension transformers have been constructed for actual industrial application, and their price being not greatly different from those commonly employed, it will be readily admitted that these results promise well for the extension of double transformations with any desired pressure in the primary circuit, even for small loads. The separation of the high-tension circuit and the special precautions adopted do away with all risk of danger from these transformers. These new arrangements do not complicate the design of the transformer; on the other hand, they have been adopted, even though really not needed, in the later types of transformers for ordinary pressures.

If the transformer is immersed in oil, it is preferable that the insulation (paraffin, for instance) should only become liquid when hot, as this facilitates transport, and prevents admixture of air and dust. The liquid circulating in the spaces made in the transformer, cools itself by contact with the metal cover.

This metal cover is constructed to increase the cooling surface to the greatest possible extent. The sides are formed by a series of tubes placed vertically, or else vertical wings are arranged against the lateral sides of the cover as in well-known forms of heating apparatus for hot water and steam.

The various types of these transformers being especially for commercial use, they can bear considerable variation in the conditions of working, output, frequency, or voltage. A transformer giving 25,000 volts can stand 50,000 volts without inconvenience.

One of these types, for instance, presents the following conditions:

Capacity	1,500 watts.
Primary	10,000 volts.
Secondary	25 volts.
Frequency	9

The primary circuit is formed of 19,960 turns of a total length of about 14,000 metres. By increasing the frequency the pressure may be raised to 40,000 without inconvenience.

These transformers have uniformly given good results, although subject to rough usage. They appear to be the result of a thorough theoretical and practical study, carried much farther than has been done hitherto. The figures of the efficiency here given seem at least to justify the statements made at the commencement of this article; and it may be maintained that a distribution made under these conditions would hardly need special precautions to be economical.

ELECTRICAL TRACTION.

Electrical traction does not cease to be one of the most attractive problems of the day. Our readers will have observed how very constantly it forms the subject of papers read before societies and of discussions and articles in the technical journals at home and abroad. Although so very little has been done in electrical traction in this country in the working on any noteworthy scale of tramway traffic by electricity, there are something like four hundred tramways worked by this means in the United States, employing nearly, it is stated, six thousand cars and about ten thousand motors, making a daily mileage of over half a million miles. The result is that necessity has forced American engineers to stick more tightly to the business of overcoming the mechanical difficulties which are encountered in the construction and working of electric motors for this very heavy work than we have done; and there is, moreover, far greater encouragement given in the form of financial aid to those who have made a fair show of mechanical success. In England we have one of the most successful electrical railways yet in operation, but the construction and equipment of electrical tramways has seldom, if ever, either commanded the attention or been placed in the hands of those engineers who are accustomed to deal with railway work. The question has not, moreover, yet taken the position which is commanded by railway enterprise or by railway finance.

A good deal of the planning and scheming of electrical tramways, electric tramway motors, and other gear have been taken in hand by the amateur and by the speculator in patents. The result has in several cases been failure, which has deterred financial enterprise in this direction. Promises have been made which have over and over again been falsified, contracts for working tram lines at a penny or two per car mile less than the cost of horse traction have under the systems adopted proved unremunerative. On all hands things have happened which have driven tramway directors back to horse traction, although there are numbers of lines in this country which only need the reduction of a penny or two per car mile to give them the new character of dividend-earning concerns. While we find that cable traction is growing in favour, and even, as at Birmingham, is earning so good a dividend that it is rumoured that the electrical line in the same town is to be converted to the cable system, the electro-mechanical system makes little or no headway.

It must, of course, be admitted that one great reason for this delay is the general objection in this country to overhead conductors; but even where the permission has been granted there is a difficulty which—either with this or with a conduit conductor system—at present prevents that economy in working which is essential to any very large reduction of the cost as compared with well-managed horse tramways. We allude to the necessity for the employment of either a very heavy motor or two motors to each car, and to the employment of large generating power where the average motor

power necessary is comparatively small. A motor, or motors, for instance, capable of giving at least 30 h.p. must be fitted to tramcars, which, on an average, do not require more than from 3 h.p. to 6 h.p. This is necessary in order to start these cars or to take them up ordinary gradients. The need for extra powerful motors renders it also necessary to provide a very high maximum generating power as compared with the average power required. This, for instance, is the case at Leeds, and in numerous American towns. On a larger scale it is the same, as, for example, on the City and South London Railway. Here, as we mentioned in our issue of the 12th August, the average power developed by each locomotive requires a current of not more than fifty amperes, although as much as 140 amperes are required for starting the trains. One result of this is that the steam engines which drive generators capable of the maximum load work a large part of all their time upon an uneconomical low load. Another result is the extra cost and weight of the heavy motors or double motors required. In the United States a considerable number of the cars running or being equipped are fitted with two motors, but the greater number are fitted with a single motor and single-reduction gearing with higher-speed motors. The choice between these two systems is perhaps a difficult matter, but although gearing has been made which runs with perfect success with one speed reduction, there is no doubt that so long as the choice is not determined by reference to cost, it is in favour of the two-motor system, and for the reason that it is the more flexible with regard to power available and to power employed. Current may be supplied to both or to only one motor, according to the character of the road, and, as someone has said, when one motor breaks down the other may usually be counted upon to take the car home. To have to carry two motors, however, is to say the least an undesirable thing, especially when carried about by so very jerky a conveyance as the under-carriage of a street car. To overcome the difficulties to which we have referred there still remains the problem of devising a satisfactory means of varying the speed at which an electric tramcar is moved, while the speed of its motor remains constant. In order that it may be practicable to run a tramcar on average roads with a motor of not more than 10 h.p., it should be possible to employ means by which the car could be started at a very low speed, which, after starting, could be changed to the normal speed. At present, for instance, single-reduction gearing is used by means of which, with a motor running at its normal speed, the car is propelled at its normal full speed. The same gear is employed for starting the car from rest, and for this purpose a very heavy current has to be passed through the motor. Attempts have been made to avoid this and its consequences by variable-speed gearing, but none of these have been practicable, or at all events have come into use. Some simple gear for this purpose is certainly necessary, and although we have understood that a practical variable gearing has been devised, we have not yet heard of its adoption.

Steam tramway locomotives have certain advantages in this respect, but the numerous disadvantages have driven it off many of the roads on which it had been placed, and the most economical tramcar haulage still remains but slightly superior to haulage by horses. This part of the question of tramway traction demands attention, and might usefully form a subject for experiment and discussion.

CORRESPONDENCE.

Justice needs that both be heard."

HOT-STRIP AMMETER.

SIR,—I see from your last number that Messrs. Drake and Gorham have introduced a hot-strip ammeter. Some years ago I made some experiments in this direction, but one of the great difficulties I found was the very sluggish nature of the instrument, which made it impossible to take rapid and varying readings. It would be of interest to know how long it takes for the instrument in question to become steady at the real current, and how long it takes the needle to return to zero. Messrs. Drake and Gorham's instrument would doubtless be very useful in central station work, where a long curve of the approximate current is required, the small variations not being needed.—Yours, etc., E. GEORGE TIDD.

11, Collingham-road, South Kensington, Oct. 6, 1892.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE III.

It is almost impossible for any person at the present moment to give a lecture of any description dealing with electricity without making some allusion to the remarkable lectures that we have heard in the course of last week by Mr. Tesla; and the great bearing which those lectures have upon certain parts of the subject upon which I am lecturing, leads one naturally to say a few words about the remarkable experiments and conclusions that have been before us. I saw in one of the technical journals, this last week, a remark that after the brilliant lecture of Wednesday evening the practical man would ask, "What is this to lead to?" Well, if the man who is in the habit of calling himself the "practical" man were to ask my advice, I should advise him to leave the experiments of Mr. Tesla quite alone. That man is hardly in the position of being able to appreciate, at their right value, the experiments which we saw. I trust that the time is passing by when those who have been in the habit of arrogating to themselve the title of "practical men" will continue to do so. Those men who apply that term to themselves do not realise the self sufficiency which is shown by their assuming such a title. It is the highest praise which can be given to the greatest engineers to say that they are practical men. The man who assumes to himself the title "practical man" is generally the man who can use his hands but cannot use his head—the man who cannot apply theory or interpret a formula—the man who could attend to a well-known type of engine, but who would be incapable of appreciating what an enormous amount has been done in the 10 years that such a thing as a Parsons steam turbine has existed. Our great men do not speak of themselves in this boastful manner as being either practical men or geniuses. Our Watts, our Stephensons, our Rennies, our Bakers, do not boast that they are practical men. They are prepared to become so, but they would not make this boast. The man who largely assumes that title, then, I do not think will be able to appreciate the value of Mr. Tesla's work. But to engineers and natural philosophers it is full

* Cantor Lectures delivered before the Society of Arts.

of importance. Engineers and natural philosophers both look to this work as telling them a deal which has been puzzling them in the past, and as holding out great hopes for the future. There is a great difference between the natural philosopher and the engineer. The natural philosopher claims only to be Nature's pupil. The engineer aims at being her master. In Mr Tesla's experiments the engineer sees great difficulties which have been in his way completely explained and partially removed. He sees what has been troubling him with the use of alternating currents in mains, and how the current was being allowed to leak, and he sees how to remedy that defect. He sees things that have been puzzling him in the action of air condensers, by which the apparent capacity of the condenser is enormously greater than it ought to be if there were not going on that peculiar action of bombardment of the molecules of which Mr. Tesla has spoken so much. The engineer also sees that Mr. Tesla has worked out a system of practical electric lighting producing a most pleasing light—more so than any which we have seen before—and by a means which is almost in a practical shape. The natural philosopher, on the other hand, sees explanations of a vast number of the experiments which have been puzzling him in the past, and sees new developments, new experimental investigations, which will lead to a better knowledge of the ultimate structure of matter. Mr. Tesla triumphs to-day as the natural philosopher. To-morrow he will triumph as the engineer.

The remarks which I have made upon this subject will lead you to see that I place very great importance on what Mr. Tesla has said about the construction of mains. We have long noticed that when an alternate current of high potential and frequency is passing through a wire, there is, in the dark, seen to be a light given off from the wire, especially near a telegraph post on which that wire is supported. This was particularly noticeable in the case of the experiments conducted at Frankfort in this last year, when a large amount of power was transmitted from a distance of 112 miles by a very high tension alternating current. We were at a loss to completely understand what was the action which was going on there and how to overcome it. Mr. Tesla has given us the answer to both; but by going to these very high frequencies and very high voltages he has exaggerated all our difficulties, and thereby been able to see the meaning of them, and to give us the cure for them with the more moderate pressures and frequencies that we use in actual practice. And there is little doubt that he has given us the right explanation of the enormous value of oil as an insulator in all these cases. There cannot be too strongly impressed upon engineers the importance of oil insulation for cables which are carrying high tension alternating currents over long distances. Those sub-station transformers which I was speaking about in my last lecture ought, in the future, to be altogether filled with oil. We had known the value of oil as an insulator before, but we had never realised the enormous importance of it, and now that we do realise the reason why it is so important, it will be very much more largely used.

There are some other mains which I do not speak much about, because they are so generally known. The Siemens concentric mains, of which I have specimens on the table, are extremely valuable for long feeders; but for distributing mains in the town they have the serious disadvantage that a special kind of metal box has to be used to form a junction when taking in the leads into any house that has a light. And the cost of this is so considerable, in order to make the joint perfect, that it seriously interferes with the economy of the mains. But for feeders these concentric mains are admirable. Also the fluid insulators which were introduced by Mr. Brooks—and which will be largely used, I trust, in the immediate future—are extremely valuable for the same purpose for alternating currents.

For the low-tension distributing mains I draw attention once more to the type, of which I have a diagram here (see Fig. 1, Lecture II.), which I feel convinced is the most practical type which can be used for low tension mains. The enormous value of this type of mains lies in this, that we can lay our mains over the whole district which is to be supplied at a very cheap rate at first, when the demand is small, and we are continually able to add to the size of the mains without the slightest difficulty. Then the whole thing is cheap to construct, and the attachments to houses are perfectly independent of the naked cables—the bare wire cables—which we draw through the copper tubes, and which we change for bigger ones when the demand in the district increases.

I come now to the question of power as apart from light, and there are two totally distinct questions in connection with power furnished by electricity, the one referring to the distribution and the other to the transmission of the power, which are often intermingled. The engineer has to consider the two together very often, but they very often are completely separate and have different demands, and may necessitate the employment of different apparatus.

Let me just give an example or two to show how very greatly different is the case under different circumstances.

A great deal has been talked in the last few years about the employment of the Falls of Niagara for supplying power to a distance, it may be. It was originally suggested by Sir William Siemens and Sir William Thomson to carry the power from Niagara into New York, and, later, more practical problems have been presented for carrying that power to Buffalo, a distance of 30 miles, and a manufacturing centre. In either of these cases the great problem is the transmission of the power. To distribute it through the town is not of such enormous importance. The best means which can be devised to carry the power from Niagara to Buffalo, and change it into power there, even though it be in the outskirts of the town, is the solution of a very great problem. But, on the other hand, take the case of a power station situated in London, let us say in Clerkenwell, where there are an enormous number of small factories or small workshops which require power. They have steam engines at the present moment doing a great deal of that work. Those steam engines take up room which is valuable, and they are in the way, and so are the boilers. Again, these small engines are not economical. The consumption of coal is enormous compared with the power given off; and the demand for extra attendants for looking after the boiler and engines is a serious drawback in these small workshops. There could be no place more suitable for putting down a power station than Clerkenwell, but there the demand is totally different to the above case. It is not simply a question of generating power in one station, and then supplying it continuously to the motors in the houses and keeping the motors always going. These motors in the workshops require to be stopped and started at frequent intervals; whereas in the transmission question we do not require to be always stopping the motors. We can be running them steadily all the time. This introduces a very great difficulty, because many motors which are most available to us are incapable of starting freely every few minutes, as when we require to start working a lathe or anything of that sort, and therefore for the distribution of power we must have special kinds of motors which are capable of starting frequently with the utmost ease.

Of course when we are transmitting power to a great distance, it is perfectly obvious that we shall be obliged to use high pressures. If we do not use high pressures we shall be obliged to use large conductors, in order that we should not waste much energy on the road, and consequently, whatever system we are going to use—whether we are using continuous currents or whether we are using alternating currents—we must be dealing with high pressures. Every special case needs to be calculated out on its merits as to the pressure which will be required and the size of the wires which we shall have to use, because we never wish to use a higher pressure than is absolutely necessary. It is always a disadvantage. The difficulties and dangers are always increased when we go to higher pressures. We want to use as low a pressure as is feasible, and will make the thing a commercial success.

As you are all aware, Sir William Thomson, in 1881, laid down a general rule for the economy of conductors. Summarised in the simplest form, it amounts to this, that the interest on the capital invested in copper shall be equal to the cost of the energy which is being wasted in the mains. Some years ago, Prof. Ayrton read a paper before the Institution of Electrical Engineers, in which he considered that Sir William Thomson had made a mistake in

this law, when it was applied to such a case as that of the carrying of power from Niagara to New York; and he argued that this law did not hold. But, as a matter of fact, the whole of the mathematics by which he supported this argument simply resolved themselves into this, that the cost of the energy which you have to take into account is really partially dependent upon the amount of copper that you have put down; that is to say, the farther the distance off from your generating station, the greater is the cost of the copper, and therefore the greater is the cost of the energy; so that, when you go to far distances, you have to allow for a greater cost per horse-power hour than you would have done if you were not going to so great a distance. This is the whole secret of the merits of the case—as I may almost call it—but Prof. Ayrton thought that he had found a flaw in Sir William Thomson's argument.

I pointed this out to a gentleman who gave some lectures on the transmission of power in this hall not long ago, and he slightly misunderstood the explanation which I have just given you, and said that we had to consider as the cost of the energy the cost which that amount of energy would fetch in the market; and that, since the energy was

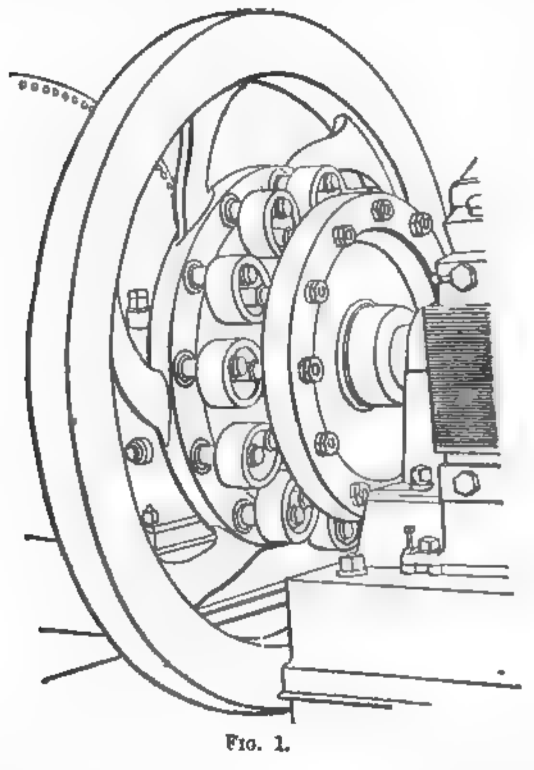

Fig. 1.

more valuable at New York than it was at Niagara, therefore we had to add to the cost of the energy when we were transmitting it to New York. It is not so. It is simply that the cost of the energy is increased by the fact of carrying it to that distance through the copper conductors.

Now, as a matter of fact, in all these cases which come before the engineer of the transmission of power to a distance, the only really satisfactory way of applying the principle of Sir William Thomson's law is to work out the results at several different densities of current; and this involves a very considerable amount of work. You must take approximate figures in the first place, and assume different pressures of the electric current—1,000 volts, 5,000 volts, 10,000 volts, and so on—and work out the cost of sending your power at all these different pressures, and also at different densities of current in your conductor—*i.e.*, with the conductor carrying different strengths of current per square inch of section. This is the only way in which you can really arrive at the greatest economy; and it is very easy in the case of using approximate figures in the first place—you do not waste a great deal of time; it is only when you get nearly to the final result that you need go to at all accurate figures.

Now comes the question: In the transmission of power to great distances, what kind of apparatus are we to use? Are we to use continuous currents? Granted that we are to use high-tension currents, are we to use continuous currents, or are we to use alternating currents? I think that if this question had been asked a couple of years ago, you would have found that nine men out of ten would have answered you that there was nothing open for use except continuous currents. In fact, at the time that the question was in discussion in respect to Niagara, the commissioners who sat and considered the different proposals which had been made, as nearly as possible passed a general resolution for the guidance of the syndicate which had the concession at Niagara, that it was impossible to use alternating currents for the purpose; and yet, within this short space of time, what a transformation has taken place. I suppose that it is more due to the extremely interesting experiments which were carried out at Frankfort during the last year than to anything else, that such a change of opinion has come over the minds of men generally. I suppose that, if the same question were asked again at the present moment, not only would there not be nine persons out of ten who would say that the continuous current was the only one, but I doubt whether there would be more than one out of ten who would say so. I do not in the least wish to undervalue the continuous current and its capabilities of transmitting power at high pressure. I have seen cases where this is being done, and I feel sure that with proper precautions it can be done well. Monsieur Thury, of Geneva, acting for the firm of Cuénod, Sautter, and Co., has erected at Genoa and Geneva, and a number of other places, high-tension continuous-current dynamos. They couple them in series, so as to increase the pressure. The machines are worked up to about 6,000 volts, and they are prepared to go to greater voltages, using 2,000 volts in each machine. The machines are completely insulated from the ground, being put on piers, built up of alternate layers of vulcanised indiarubber and pieces of porcelain. The difficulty which many people thought they saw was the connection with the source of power—the waterwheel or the steam engine—but the firm to which I allude have always used the Raffard couplings, and have been entirely successful with them; and I have no hesitation in saying that it is a very satisfactory arrangement. The Raffard coupling is an extremely simple thing, and of use when we wish to connect two axles together in a line. We place upon each of them a disc, Fig. 1, one of larger diameter than the other. An equal number of pins project through their adjacent faces, near the periphery of each of them; and these two sets of pins, which overhang each other, are connected in pairs by rings of indiarubber, cut off an indiarubber pipe. The result is a flexible coupling, which is extremely valuable mechanically, and which is a perfectly insulated coupling. There is not the slightest difficulty in connecting high-tension machines to engines or turbines with this arrangement, which works perfectly well in practice.

THE PROBLEMS OF COMMERCIAL ELECTROLYSIS.*

BY J. SWINBURNE, MEMBER.

(*Continued from page 338.*)

Electro-Metallurgy of Copper.

Electrolysis may be employed either in connection with the extraction of the copper from its ores, or in refining copper especially when there is silver alone, or with gold in addition, to be extracted.

In the first case—that of extraction of copper from pyrites—the ore may be converted into matt, and the matt can be cast into anodes, or the ore may be acted on by oxidising solutions produced by electrolysis, or the two processes may be combined.

In the first method the matt is cast into anodes, which are treated in baths of copper sulphate with copper cathodes. The sulphides are attacked, sulphate of copper is formed, sulphur and impurities being left on the anode. The copper is deposited, and iron remains in solution. The chief difficulties in connection with this process are that the anodes are brittle and troublesome, and are often eaten away unevenly, and the solution becomes richer and richer in iron salts. In addition to this, it is stated that the circulation of the iron salts must be avoided, otherwise ferric sulphate will be produced at the anode and reduced at

the cathode; and this process will go on wasting power over resistance. Some sort of diaphragm is therefore necessary.

It must be pointed out that sulphuric acid can be made from the sulphur dioxide given off in the first roasting of the ores, or from the surplus ferrous sulphate. The ore can be roasted so as to have a good deal of soluble oxide of copper, which can be dissolved in the acid and treated electrically. Merely working with anodes is an incomplete process; it is better to combine it with extraction by lixiviation. The solution, after being in contact with the anode, so as to contain ferric sulphate, is led to the ore. The ferric sulphate is reduced, and the copper and iron are said to be dissolved, and if there is oxide of copper it is taken up by sulphuric acid. This solution is led to the cathodes, where the copper is thrown down, and is then passed to the anodes, where the iron salt is oxidised. The various impurities and the precious metals are left with the sulphur of the anode. The sulphur is burned into sulphur dioxide, which goes to the chamber, and the silver, with the gold, if there is any, is extracted. The sulphate of iron can be burned into sulphur dioxide, and the iron oxide sold as Venetian red. This is, in rough outline, the Marchese process. It may seem strange to those unacquainted with industrial chemistry that if you want to extract copper you should also become involved in making sulphuric acid and red paint; but in chemical works by-products must be utilised, so that often making one thing involves the production of a number of other substances which have at first sight nothing to do with it. Messrs. Siemens and Halske avoid the necessity of making anodes of matt, by employing carbon. The ferrous sulphate is thus oxidised into ferric salt, and this is used to lixiviate the crushed and roasted ore. The solution is then led to the cathodes first to take out the copper, then to the anode to oxidise it, and so on.

In the Hopfner process chloride of copper is used instead of sulphate. The action is stated to be as follows: Cupric chloride is formed at the anodes; this is led to the matt, where it attacks the copper sulphide, forming cuprous chloride and sulphur, and it is also said to dissolve the silver as well as the copper, which, if possible, would be a drawback. I do not know why the chloride should be preferred to the sulphate; and no information is given as to what is done with the sulphur in the ore, and with the excess of ferrous chloride that must be produced.

The Marchese and Siemens and Halske processes are in commercial operation, and the electric extraction of copper is already a growing industry. The E.M.F. necessary for this process is less than a volt; so that, assuming coal to be used as in the estimate at the beginning of this paper, the electrical cost is 14s. 5d. per ton for the extraction of copper. I cannot give the whole cost, as that involves so many considerations. This figure will give copper smelters some idea of the saving of replacing the ordinary refining process by electrolysis.

In dealing with such a valuable substance as copper the time element must not be neglected. The interest on the money locked up in the copper under treatment may be a very serious item. This is an objection of some weight in the case of matt anodes, which take some time to dissolve. The whole of the copper turned out is not obtained from the anodes; but, taken all round, it may not be far wrong to assume that the copper takes about three months to pass through the works where matt anodes are employed. If the output is, say, 1,000 tons a month, the copper represents a capital of some £150,000, and the interest increases the cost of refining some 12s. a ton.

Electrolysis may also be employed for refining crude copper. In this case the process is simplicity itself. The crude copper is made into anodes, and thin plates of fine copper are used as cathodes, the electrolyte being sulphate of copper. Pure copper is deposited on the cathodes, and the impurities and the silver and gold are left in the mud, and the precious metals are extracted in the ordinary way. It is usual to employ cast anodes, and arrange the plates in each vat in parallel, the vats themselves being coupled in series. This arrangement is clumsy, and should be modified. I have had an opportunity of examining the large copper refinery at the Bridgeport Copper Works, and it may be well to describe the arrangement employed there. As the books were examined by Mr. J. H. Hays at the same time, I am also able to give you the actual cost of the process, without having too roseate a hue imparted by an enthusiastic inventor. The refinery is arranged and worked in accordance with the patents of Mr. E. S. Hayden. The departures from ordinary practice are made with the view of reducing the amount of copper under treatment, and of keeping down the cost of labour.

The anodes, instead of being thick cast copper, are sheets of thin rolled metal. The cost of rolling is small, and the plates used can thus be made thin, and dissolved very uniformly. Each vat contains a number of plates arranged vertically and across the vat. At one end a thin plate is supplied as a cathode. The first plate is made the anode, and copper is eaten off one side of each plate, and deposited on the plate next to it. The result is that each vat acts as a number of small vats arranged in series, and requires only two electrical connections. The whole question of large leads and connections is thus solved. There is almost no waste through partly consumed anodes, as the whole plate is eaten away evenly. The process is carried on until the whole of the anodes are eaten, and their place taken by the pure deposited copper. The plates are hosed and removed, and the slime is treated to recover the silver and gold. The product is the highest grade of copper in the market, and fetches £6. 10s. a ton above "tough cake," or £4. 10 above "best selected." Silver and gold are completely separated without loss, and as 35oz. of silver and ½oz. gold per ton are allowed as tare, any copper containing more than that yields £8 per ton in bullion. Argentiferous copper thus yields at least £14. 10s., leaving the gross profit of £12. 10s. at present rates. I have here taken the cost of refining at £2 per ton. The actual cost of refining copper depends on the output of the works and the cost of labour. In Bridgeport it came out just over £2 a ton. With modern dynamos, and reasonably good engines and labour at English prices, the cost would be a good deal less, say, 20s. to 25s. per ton. The use of thin plates as anodes also reduces the capital investment in copper, which, as already pointed out, may be enormous, and thus lessens the margin to be allowed for fixed charges.

The Elmore process is too well known to require a full description. The copper is deposited on a revolving mandrel, and burnished by a travelling agate burnisher. By this means copper tubes of great strength are made, and by cutting the tubes sheets are produced. Narrow strips can also be made, and these can be drawn down into high grade copper wire. A number of thin sheets can be made by depositing several separate coatings one over the other on the mandrel. The sheets separate when the tube is slit lengthways.

Writers of books on political economy are fond of saying that the chaffering of the market makes people manufacture in the cheapest way, and that the cheapest and best goods displace dearer and inferior qualities. They forget the interference of custom, ignorance, and prejudice. If a new process is brought out, it takes ages before it is taken up abroad, and still longer before Englishmen will touch it. Here we have a process of refining copper at a gross cost of £1 or £2 a ton, with a gross profit of £13 or so, and yet copper refiners continue their barbarous methods. The first manufacturers to take up copper refining by electrolysis on really modern principles have a chance of making fortunes before the market is disturbed.

Antimony.

Little has been done in the way of treating antimony ores electrolytically. Dr. W. Borchers proposes to use the solution of sulphide in sodium sulphide as an electrolyte, and to deal with the ores. The specimens of antimony ore that I have examined have been perfect insulators, so that regulus of antimony cannot be used as an anode. There will be an accumulation of sulphur in the bath, and it will probably insulate the anode. It is also difficult to say what material could be employed as anode in such a solution. Carbon would be attacked, and platinum would be too expensive, and other metals would be converted into sulphides. As the reduction of antimony by iron, for example, is comparatively easy, there does not seem to be much opening for the electrolytic treatment in dealing with its ores.

Recovery of Tin from Scrap Tin.

This, of course, can be readily effected by electrolysis. The scrap can be made the anode in an alkaline solution, in which iron is not attacked. Though such a method removes all the tin from the surface, it may leave some alloyed with the iron, as no doubt some tin sinks into the iron during dipping.

Electrolysis has also been employed to assist in cleaning plates before dipping. I do not see how it can be of much service here, however. I have examined one of the processes, and it was said to be working very successfully, but I found the brushes had been accidentally left off the commutator.

Electrical Tanning.

Electrical tanning, though it depends on electrolysis, differs materially from all the processes already described in not depending on the isolation of radicles at the electrodes. Ordinary tanning is a very slow process, because it takes a long time for the tannin to diffuse into leather properly. If this substance is an electrolyte, it has a very complex molecule, and therefore diffuses very slowly. The outside of a thick piece of leather soon becomes tanned, and to some extent protects the rest from the diffusion of more tannin. We may get an idea of what I suggest is the action in electrical tanning by regarding a hide as being made up of cells in groups, with interstices among the groups. If the skin is merely left in tan liquor, it takes months for the liquor to penetrate even into the interstices. It has then to diffuse through the walls of the cells. This is necessarily a very slow process, when it is remembered that the gelatine uses up the tannin as it comes in. Mechanical agitation has been tried, but it does not accelerate the process much. It is probable that agitation helps the liquor into the interstices, but, of course, it cannot help it into the interior of the cells, or, in fact, into those parts of the leather which are accessible by diffusion alone. The agitation can thus only perform the first part of the process—that is, getting the liquor into pores that are open to it.

ELECTRIC LIGHTING PROVISIONAL ORDERS AND LICENSES.

REPORT BY THE BOARD OF TRADE RESPECTING THE APPLICATION TO AND PROCEEDINGS OF THE BOARD OF TRADE UNDER THE ELECTRIC LIGHTING ACTS DURING THE PAST YEAR.

The following applications for provisional orders have been received by the Board of Trade since the date of the last report:

Title of Order and Description of Area.	Name of Promoters.
Aberystwith Electric Lighting Order. The Municipal Borough of Aberystwith.	Corporation.
Ashton-under-Lyne (Corporation) Electric Lighting Order. The Municipal Borough of Ashton-under-Lyne.	Do.
Brighton Electric Supply Order. A portion of the Municipal Borough of Brighton and the Parish of Preston.	Brighton and Hove Electric Light Company, Limited.
Dublin Electric Lighting Order. The City of Dublin.	Corporation.
Fareham Electric Lighting Order. The District of the Fareham Urban Sanitary Authority.	The Fareham Electric Light Company, Limited.
Govan Electric Lighting Order. The Burgh of Govan.	Commissioners of Police.
Halifax (Corporation) Electric Lighting Order. The County Borough of Halifax.	Corporation.
Harwich (Corporation) Electric Lighting Order. The Borough of Harwich.	Do.
Kilkenny Electric Lighting Order The Municipal Borough of Kilkenny.	Do.
Limerick Electric Lighting Order. The Borough of Limerick.	Do.
Liverpool Electric Lighting Order. A portion of the City of Liverpool.	The Liverpool Electric Supply Company, Limited.
THE COUNTY OF LONDON:	
County of London (North) Electric Lighting Order: The Parish of St. Mary, Islington. The United Parish of St. James and St. John, Clerkenwell. The Parish of St. Luke, Middlesex. The District of the Holborn District Board of Works.	County of London Electric Lighting Company Limited.
County of London (South) Electric Lighting Order: The Parish of Lambeth The Parish of St. George-the-Martyr, Southwark. The District of the Wandsworth District Board of Works.	County of London Electric Lighting Company, Limited.
East London Electric Supply (Hackney) Order. The District of the Hackney District Board of Works.	East London Electric Supply Company, Limited
Hampstead Electric Lighting Order. The Parish of St. John, Hampstead.	The Vestry.
Lambeth Electric Lighting Order. A portion of the Parish of Lambeth.	Ditto.
North London Electric Lighting Order. The District of the Hackney District Board of Works. The Parish of St. Luke, Middlesex. The Parish of Clerkenwell.	Camberwell and Islington Electric Light and Power Supply, Limited
St. Mary, Islington, Electric Supply Order. The Parish of St. Mary, Islington.	Messrs. Sharp and Kent, 34, Victoria-street, S.W.
Shoreditch Electric Lighting Order. The Parish of St. Leonard, Shoreditch.	The Vestry.
South London Electric Lighting Order. The Districts of the St. Olave District Board of Works and the St. Saviour's District Board of Works, and the Parishes of St. George-the-Martyr, Southwark, and St. Mary, Newington.	Camberwell and Islington Electric Light and Power Supply, Limited.
West London Electric Lighting Order. The Parishes of Hammersmith, Fulham, and Battersea, and a portion of the District of the Wandsworth District Board of Works.	Putney and Hammersmith Electric Light and Power Supply, Limited.
Whitechapel District Electric Lighting Order. The District of the Whitechapel District Board of Works.	The Board of Works.
Maidstone Electric Lighting Order. The Borough of Maidstone.	Corporation.
Newbury Electric Lighting Order. The Borough of Newbury.	Do.
Oxford Electric Lighting Order. (Transferring to the Oxford Electric Company, Limited, the rights, powers, and obligations of the Electric Installation and Maintenance Company, Limited, under the Oxford Electric Lighting Order, 1890.)	The Oxford Electric Company, Limited.
Sheffield Electric Lighting Order. The Municipal and County Borough of Sheffield	Sheffield Telephone Exchange and Electric Light Company, Limited.
Sutton (Surrey) Electric Lighting Order. The Urban Sanitary District of Sutton.	The Local Board.
Walton-on-Thames Electric Supply Order. A portion of the Parish of Walton-on-Thames.	Weybridge Electric Supply Company, Limited.
Waterford Electric Lighting Order. The Borough of Waterford.	Corporation.
Waterford Electric Supply Order. The Borough of Waterford.	City of Waterford Electric Supply Company, Limited.
West Ham (Corporation) Electric Lighting Order. The County Borough of West Ham	Corporation.
Woking Electric Supply Company Electric Lighting Order The Parish of Horsell and part of the Parish of Chertsey.	Woking Electric Supply Company, Limited.

Of these applications (32 in number) 17 were made by local authorities, 14 by companies, and one by a firm of electrical engineers; 11 related to the county of London.

In one instance an application was received from the local authority, and another application from a company, for the same area. An order was granted to the local authority and the application of the company was refused.

The following statement shows the manner in which the various applications have been dealt with:

Title of Order.	How dealt with.
Aberystwith Electric Lighting Order.	Order granted.
Ashton-under-Lyne (Corporation) Electric Lighting Order.	Do.
Brighton Electric Supply Order.	The promoters failed to produce the consent of the local authority or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.
Dublin Electric Lighting Order.	Order granted.
Fareham Electric Lighting Order.	Do.
Govan Electric Lighting Order.	Do.
Halifax (Corporation) Electric Lighting Order.	Do.
Harwich (Corporation) Electric Lighting Order.	Do.
Kilkenny Electric Lighting Order.	Do.
Limerick Electric Lighting Order.	Do.
Liverpool Electric Lighting Order.	Do.
THE COUNTY OF LONDON:	
County of London (North) Electric Lighting Order.	Order granted for: The United Parish of St. James and St. John, Clerkenwell; the parish of St. Luke, Middlesex; the District of the Holborn District Board of Works.
County of London (South) Electric Lighting Order.	Two orders granted: One in respect of the parish of St. George the Martyr, Southwark; the other in respect of the District of the Wandsworth District Board of Works.

Title of Order	How dealt with
East London Electric Supply (Hackney) Order	The Board of Trade declined to grant the order, as the promoters failed to satisfy them that they were in a position to discharge the duties and obligations that would be imposed upon them by the order, if granted.
Hampstead Electric Lighting Order	Order granted.
Lambeth Electric Lighting Order.	Do.
North London Electric Lighting Order.	The order was granted on the understanding that before the introduction of the confirming Bill the promoters should satisfy the Board of Trade that they were in a position to discharge the duties and obligations that would be imposed upon them. They, however, failed to do so, and the Bill was not introduced.
St. Mary, Islington, Electric Supply Order.	The promoters failed to produce the consent of the local authority or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.
Shoreditch Electric Lighting Order	Order granted.
South London Electric Lighting Order	The order was granted on the understanding that before the introduction of the confirming Bill the promoters should satisfy the Board of Trade that they were in a position to discharge the duties and obligations imposed upon them. They, however, failed to do so, and the Bill was not introduced.
West London Electric Lighting Order	The Board of Trade declined to grant the order, as the promoters failed to satisfy them that they were in a position to discharge the duties and obligations that would be imposed upon them by the order, if granted.
Whitechapel District Electric Lighting Order	Order granted.
Maidstone Electric Lighting Order.	Do.
Newbury Electric Lighting Order	Do.
Oxford Electric Lighting Order	Do.
Sheffield Electric Lighting Order	Do.
Sutton (Surrey) Electric Lighting Order	Do.
Walton on Thames Electric Supply Order.	The Board of Trade declined to grant the order, as the promoters failed to satisfy them that they were in a position to discharge the duties and obligations that would be imposed upon them by the order, if granted.
Waterford Electric Lighting Order (Corporation).	Order granted.
Waterford Electric Supply Order (City of Waterford Electric Supply Company, Ltd.	An order was granted to the Corporation and this application was refused.
West Ham (Corporation) Electric Lighting Order	Order granted.
Woking Electric Supply Company Electric Lighting Order.	Ditto.

Bills Nos. 1 to 3 were introduced into the House of Commons on April 11th to confirm the orders relating to Govan, Aberystwith, Ashton-under-Lyne, Halifax, Harwich, Limerick, Maidstone, Kilkenny, Newbury, Sutton (Surrey), West Ham, and Woking (Horsell and Chertsey).

Bills Nos. 4 to 6 were introduced into the House of Lords on May 6 to confirm the orders relating to Dublin, Lambeth, Liverpool, Oxford, Sheffield, Waterford, County of London (a portion of) Southwark, Wandsworth, Hampstead, Lambeth, Shoreditch, and Whitechapel.

Bills Nos. 1 to 3 received Royal Assent on June 20. Bills Nos. 4 to 6 are still before Parliament.

The provisional orders granted by the Board of Trade last session, and referred to in the last report, were all confirmed by Parliament.

Licenses.

The following applications for licenses have been received since the date of the last report, and are at present under consideration.

Name of Company applying and Name of District.

The Ogmore Valley Electric Light and Power Supply Company. (A portion of the district of the Ogmore and Garw Local Board.)

The Shropshire Electric and Power Company, Limited. (A portion of the borough of Shrewsbury.)

The Isle of Wight Electric Lighting Company, Limited. (The Urban Sanitary District of West Cowes.)

Appended is a list of the provisional orders confirmed by Parliament prior to the present session, and of the licenses granted by the Board of Trade since the passing of the Electric Lighting Act, 1882, showing those which have since been revoked or repealed.

HENRY G. CALCRAFT.

Board of Trade, June 23rd, 1892.

(To be continued.)

COMPANIES' MEETINGS.

BRUSH ELECTRICAL ENGINEERING COMPANY

This company was registered in [illegible], 1889, and is a [illegible] works. The authorised capital is £750,000, divided into 150,000 6 per cent. preference shares of £2 each and 150,000 ordinary shares of £3 each. Of the former 75,607 shares, and of the latter 77,978, have been issued and paid up. There is also an issue of £125,000 6 per cent. first mortgage debentures. Dividends paid 1890-91 6 per cent. for the second half of the year. Number of shareholders 1,913. Latest prices: Ordinary, 2¾ 3⅛; preference 2¼.

The third annual general meeting of the Brush Electrical Engineering Company, Limited, was held on Friday, at the Cannon-street Hotel, the Duke of Marlborough presiding.

The **Secretary** (Mr. B. Broadhurst) read the notice convening the meeting; the report and accounts (as given in our last issue) were taken as read.

The **Chairman** said: Gentlemen, I am very pleased to see that there are present here such fair numbers to hear, and not only to read, the statements that will be made by your Board as to the condition of the Company. I think it is a very good thing for a company that the shareholders should take an interest in its meetings, and not, because things are prosperous, leave it entirely to the responsibility of the Board to appear at a general meeting and address only a few members. The last time we met I had only been chairman of this Company a few months, having taken up that post on the resignation of Lord Thurlow, so that this is the first complete year I have had the honour of occupying the chair of this Company; therefore, it devolves upon me to pay somewhat more careful attention to the condition of the Company than, perhaps, one would feel it his bounden duty to do as an ordinary director. Now, gentlemen, in drawing your attention to the leading features of our report and balance-sheet, there are a few remarks which I should like to make to you. In the first place, you will observe that your profit and loss account shows a gross profit of £[illegible]. I will not go into a careful analysis of how these figures are derived, because I should prefer to leave this to my co-director, Mr. Braithwaite, who will give you his view of the incidence of these figures, and how they generally affect the balance-sheet, and to confine myself more to general remarks with regard to these matters. In the first place, remember that the particular feature in the balance-sheet of a company like ours that requires very careful attention is that we are essentially a trading or manufacturing, rather than a commercial company. A commercial company's business settles down into a very steady form. Take the case of a bank; it has always its clients whether trade is good or bad. To a certain extent a railway is the same with its passengers, though they are somewhat more numerous in good times than in bad. That is a commercial company, but this is a manufacturing company, and its business depends on the prosperity of trade and the demand for the particular articles of commerce which we manufacture. That brings me to the remark that the balance-sheet representing the affairs of a trading company requires very careful attention, and I think it should always set forth very clearly the exact condition of affairs with regard to almost every detail. There was a remark made by a shareholder last year with regard to our balance-sheet which I was not prepared to answer exactly at the time, but which has remained in my mind since. It was that there should be some sort of analysis of the statement in the balance-sheet of property, patents, and goodwill. You will observe that the entry in our balance-sheet is £[illegible]. I was asked why that item was not divided, and I confess that at the moment I was not prepared to give an answer. Now, however, I have placed it before the directors, and we have discussed the matter at some considerable length, and the Board has come to the conclusion that in another year we will divide out that item. I cannot congratulate myself in seeing it, so far as the condition of the Company's affairs goes, because I honestly believe that the figures will represent good value. But it divides itself essentially into two values. It would not be right to suppose that that amount represented property merely, and it would be equally wrong to suppose it was all patents and goodwill. But there is this difference in a trading company, that a trading company essentially possesses goodwill, which is a legitimate and tangible asset. At the same time it is an asset which is contingent—that is to say, it is contingent on your existing as a company, and continuing in a good condition of trade. Supposing trade fell off in the silk industry of Coventry, for instance, there would

be no goodwill, the trade having gone, and therefore, in the case of this Company, it is wise to attempt to discriminate between these items of property, patents, and goodwill. Patents, of course, are to a large extent difficult to value, and therefore I do not see that we can discriminate entirely between the value of patents and goodwill; but in the next balance-sheet, the Board having consented to adopt this course, I hope to see a division of these items. Whatever may be the condition of many industries in this country—and some, I fear, have languished a good deal, trade not having been as prosperous in many directions as we might have hoped—I think that real and steady progress is being made in the electrical industry. No doubt, to a certain extent, the industry is on its trial. If there were one or two electrical financial disasters connected with these large central station undertakings, I think it would create great nervousness; but, on the other hand, I see no necessity to have any such fear. As far as I myself am concerned with this large industry in the City, it affords to me complete satisfaction, and I see no prospect of any disaster or any difficulty occurring. Therefore, seeing that the electrical industry is on an absolutely sound commercial basis, you, as a trading company, I think, have very good prospects before you. The result of this year's trading has been that you are the possessors of a certain abnormal profit this year—a profit which does not come absolutely into this year and cannot be expected every year; that is to say, a large sum has been received on account of the City contract, and Mr. Braithwaite will explain to you how we have dealt with the matter. We have taken that profit and divided it in a certain way which I think is quite legitimate; we have only placed that portion to the dividend fund which would legitimately represent the working profits of the year. Another portion of that profit has been used for writing off certain losses, and Mr. Braithwaite will explain how those losses have arisen, and the reason the Directors have used this money for the purpose of writing them off. Then, another portion of the money has been set to a reserve fund, which appears in your balance-sheet as a contingent reserve. Therefore, taking the general condition of the balance-sheet as it stands, I think it compares very favourably with last year's balance-sheet, and from many points of view is much stronger. On the other hand, I am bound to point out that we cannot always expect to be in the same position unless the trade progresses. There are many competitors in this field, and, there is no question about it, we cannot monopolise all the orders, and, in fact, we are obliged, in order to be in a prosperous condition, to have a very large turnover in the course of the year, so as to be able to present you with what I call a favourable balance-sheet. All these things must be remembered, and it depends very much on the exertions of your officers and your Board to keep us in the van of this industry. I may say I recognise that a great deal of work is thrown upon the officials of the Company in this respect, and in viewing the course of the work during the year, I observe a large amount of labour has been bestowed by them in trying to popularise the Brush industry with town councils and local authorities likely to go in for this work, and I hope that some of this popularising work will be able to be done by members of the Board. In fact, the Directors of this Company must look upon themselves to a large extent as principals in a business rather than sleeping partners, whose function is merely to audit accounts. It is a business which must be pushed, and, under these circumstances, I think you have a good investment for your money and a good prospect before you in this industry. I will not go very critically into the balance-sheet, as I have asked Mr. Braithwaite to address you on that subject, beyond saying a few words on a certain point. The policy of the Company is to concentrate all its works at Loughborough. The Falcon Works, which we acquired in the amalgamation brought about in 1889, are being added to, and we hope in the course of the year to abandon the works in Belvedere-road completely, and carry everything down to Loughborough. Your Board have visited Loughborough on several occasions this year. I was only able myself to visit it once, the other day; but I can speak most favourably of the manufactory you possess down there. The engines and dynamos which are being made for the City of London are of a most approved character, and seem to promise to turn out everything that could be desired. The winding shop, which is at present in London, will be transferred to Loughborough, and some small delay in the execution of orders will, no doubt, take place owing to that transference; but I trust, nothing to seriously impede the capacity of your Company for carrying out the contracts which it has in hand. The prospect with regard to orders is good; several orders of importance are at present in hand, and the prospect of the coming in of further orders, as I say, seems to be favourable. You will observe that your debenture issue has been completed in the course of the year, and that you are practically borrowing now a larger sum of money for the same amount of interest. I observe, also, in this balance-sheet a thing I am bound to call your attention to, and that is that amounts have from time to time been added to the property, patents, and goodwill account. Now, that is another reason for pointing out the advisability of dividing these items. The balance-sheet occasionally becomes a mere statement of account, all of which hangs upon this item, and unless that is capable of complete analysis it is very difficult to arrive at the position of affairs. Such an item is used, in fact, as a sort of waste-paper basket, into which everything is put. The profit on the debenture stock has been added to the property, patents, and goodwill, and, no doubt, it is legitimately goodwill; but, at the same time, it is well that shareholders should understand how that is arrived at, and I think I am bound to point it out. With regard to the work done for the City of London Electric Lighting Company, it, I believe, has met with the approval of that company in every respect, and I anticipate that we shall have no difficulty in carrying out the contract we have there, and I hope there will be no loss of any sort. You will understand that in this industry one of the great difficulties is not to make a loss on a contract, because we are often obliged to undertake work in which there was no previous experience, and in which we have to compete with other firms ready to go in for the same thing, and we sometimes are bound to have losses where we are obliged to go outside our ordinary experience. I am glad to say, however, that that is not of frequent occurrence; but Mr. Braithwaite will explain one instance in which we have met with this difficulty, and have written off the loss. We exhibited, as you will see in the report, at the recent Crystal Palace Electrical Exhibition, and that exhibit attracted very considerable attention from the public, and has done, I believe, considerable good in bringing the position of the Company into public notice. I would like to add a few words with regard to the question of our foreign business. The Australasian business promises, I believe, to give us a profit on our future orders—a tangible profit—and I think that business may progress. There is no doubt that our colonies ought to be good customers of this Company. Whether they will be so I, personally, have not sufficient knowledge to be able to form an opinion, nor have I any knowledge of Australasian matters. With regard to our Vienna business, I think I may say that the business at Temesvar has been acquired by the town for a fixed sum. I believe that negotiation is practically concluded, and that we may look upon that as an asset which has been turned into money. Mr. Garcke, your former managing director, and whom, I am glad to think, we still have with us as a director, has taken a great deal of trouble in the matter, and we owe him a very great debt of gratitude, because I do not think that anything could really represent a fair recompense to him for the enormous amount of trouble taken by him in connection with your Austrian business. He has been instrumental in concluding the matter, and I think you owe him a great debt of gratitude for undertaking it. With regard to the rest of the Vienna industry, we hope that the day will come when we shall be able to hand over that business to what I would call a native organisation, and that we shall be able to retain a solid interest in the same. There are so many difficulties and anxieties in carrying on an industry of that sort in a foreign country, and we should like to see our work, if possible, all concentrated at home. I do not think I need keep you any longer, for I think I have told you fully the position in which we stand. We have every reason to be satisfied with the year's working. The balance-sheet speaks for itself, and with regard to the item of valuation of the properties and the goodwill of the Company, that is an item which, although it has descended to us from the amalgamation, I think thoroughly represents the tangible assets of the Company. I have, therefore, every confidence in saying that I believe you may be fully satisfied with the last year's working, and that the dividend which you are now to receive is one which has been honestly and fairly earned. It is now my duty to move the adoption of the report, and Mr. Braithwaite will second the motion.

Mr. J. B. Braithwaite seconded the motion, and entered in detail on the chief items in the accounts. To pay 6 per cent. on the ordinary shares required £7,000, and, bearing that sum in mind in relation to the amounts that had been written off out of profits, they would see the amount of prudence the Directors had exercised. The gross profit of £55,757 had only been arrived at after making ample provision for anything that seemed at all likely to turn out unsatisfactorily in future years. They had received this year the initial payment for the large contract they had in connection with the City of London lighting, and it therefore seemed prudent to clear away anything in their accounts which was in the slightest degree unsound. They had written off £1,636 as provision against losses on some contracts carried out in foreign countries, and had also written off the entire cost of the compound winding action, viz., £2,861, made a provision of £4,000 for any possible further bad debts, although at present none were in sight, and written £1,000 off the provisional order account and another £1,000 in connection with the opening of their new show rooms in Regent-street. It would thus be seen that had the Directors been so disposed they could have paid a higher dividend. They were determined, however, not to increase the dividend from 6 per cent. until they saw they could retain it at the increased figure, and he thought the shareholders would agree with the Board's policy in thus placing the Company on a thoroughly sound basis. There was a large increase in the item "staff bonus", but the shareholders had already sanctioned the Board's proceedings in that respect. The business was conducted on the system commonly called profit-sharing. At the present moment 64 of their officers and employés were on the bonus staff, comprising all those who had been with them two years and were paid a monthly salary. It was intended to extend the system to those who were paid weekly wages. He thought the system they had adopted would identify the interests of the men with those of their employers, and was the best way of meeting the labour question. With regard to the contract for the lighting of the City, work to the amount of £50,000 had already been executed, so that they had £240,000 in that contract with which to begin the new year. There was no reason to doubt that the present year would yield a bigger profit than the last. In conclusion, he congratulated the shareholders on having at last entered on a career of commercial prosperity, which so many of them had looked forward to through some years of difficulty and cloud.

Mr. C. R. Fry raised the question of the issue of shares which had taken place during the year, and complained of their not having been offered to the shareholders.

Mr Braithwaite said the shares had previously been offered to the shareholders, and declined by them and the Board, in disposing of a small block to make up an even number, accepted an offer by certain gentlemen on the Stock Exchange, paying only a commission of 1s a share to those who took the risk of taking shares which were not quoted in the official list.

The motion was adopted, and a resolution confirming the interim dividend of 6 per cent on the preference and ordinary shares for the half year ended December 31, 1891, and declaring dividends at the same rate on both shares for the half year ended June 30, was also agreed to.

The retiring Directors and auditors were re-elected, and the proceedings then closed with a vote of thanks to the Chairman and Directors.

COMPANIES' REPORTS.

PRETORIA LIGHTING COMPANY, LIMITED.

Directors' report to the shareholders of the Pretoria Lighting Company, Limited.

Your Directors have much pleasure in submitting for your approval this their third report on the affairs of the Company together with the balance-sheet and profit and loss statement made up to the 30th June last and the auditors' report on same.

Buildings and Machinery Contracts.—The contract for the station buildings was placed in the hands of Messrs. Murdoch and Haldane, who have executed their work in a most creditable manner and to the entire satisfaction of the Board. Messrs. Crompton and Co., Limited, handed over the electrical machinery and plant on the 1st June last. Your Directors called in Mr. J. Hubert Davies, the well-known electrical engineer of Johannesberg, to inspect the whole of the works. Mr. Davies has sent in a preliminary report, and will send in a final one after the 1st September, when the three months trial of the machinery by the contractors is concluded. You will remember that Messrs. Crompton and Co., Limited, bound themselves under a penalty clause to complete their works by the 31st March last. As this was not carried out, this matter was also referred to Mr. J. H. Davies, who advised your Board that good and valid reasons had been advanced by Messrs. Crompton and Co., Limited, for the non-fulfilment of their undertaking.

Extension System.—On the arrival here of Mr. J. Cushny (Messrs. Crompton and Co.'s representative) it was discovered that the original system of distributing the mains was unsatisfactory and unworkable. A new plan had to be devised (involving an additional expenditure of something under £3,000), which your Board sanctioned, and which is now nearly completed, whereby the distribution of electrical current is made available to every house within the boundaries of the city.

Electrical Machinery.—The plant consists of five sets of boilers, engines, and dynamos, together with 102 lamps for street lighting, with all poles, insulators, etc.; about 35 tons of copper conductors, distributed on the underground and overhead systems, and with all necessary instruments required for a central station. Your Directors think that the Company can congratulate themselves on possessing one of the most thoroughly equipped and efficient stations in existence at the present time. It can be mentioned that the plant is capable of supplying current to about 6,000 lamps of 8 c.p. capacity, in addition to the energy required by the Government for the public lighting contract.

Supply of Current.—The Company commenced, on the 10th June last, the supply of light to 48 of the public lamps, the Staats-drukkerij (State printing office), and to a few private consumers. The whole of the public service could not be started simultaneously, as a certain number of the lamps are on the extension system which will not be finished until the 1st September. Up to date 72 private installations have been or are being connected to the Company's mains. A full statement of all installations with revenue accruing from same, made up to the date of the general meeting, will be laid before you for inspection.

Engineer.—Your Directors have secured the services of Mr. John Carmy as resident engineer, the appointment to date from September 1st next.

Management.—Your Directors have also appointed Mr. Hirschel Cohen to the dual position of manager and secretary.

Retiring Directors.—Messrs. C. Hanau and J. B. Taylor retire in order of rotation, but are eligible and offer themselves for re-election.

Auditors.—You will be asked to appoint a new auditor or auditors in the place of Messrs. Cowen and Wilkinson, who have left the State, and to confirm the appointment of Mr. A. Scott Rankin, who was chosen by your Board to conduct the audit of the accounts now before you, and to fix the remuneration for same.

Balance-sheet.—The statements as laid before you need hardly any comment. From the profit and loss account you will see the revenue and expenditure from electrical supply for the 20 days' work during the month of June and one or two special services, but as few private installations had then been effected, and as the Government was only charged half of the contract price, the details are no guide to the proportion of revenue to expenditure. You will also notice that the amount of £3,346 7s has been carried to preliminary expenses account.

Preliminary Expenses.—Your Directors have decided that the amount of £4,543 5s 8d expended during the past three years (including an amount of £1,741 0s 2d taken over from the old Z.A.E.M.) on the various items affecting the formation of the Company, and other amounts not directly chargeable to the construction account shall be written off over a course of seven years, and the amount that will consequently be charged annually to profit and loss account will be £649 0s 10d.

Prospects of the Company.—Your Board are happy to be able to state that the prospects of the Company are favourable in the extreme. The popularity of the new light is evidenced by the daily applications for current from the public, and your Board will make every endeavour to maintain that popularity by meeting the consumers in every possible way, feeling that the interests of the shareholders and the public are inseparable, and are even now considering a scheme whereby the advantages of the electric light will be brought home more clearly to every householder. It must be stated that the operations of the Company have been inaugurated in a most auspicious manner. It is almost without record in the electrical world that an installation of the magnitude possessed by this Company should have started and worked so smoothly, successfully, and without a single hitch, as has been done in these works since the 10th of June last.

NEW COMPANIES REGISTERED.

New Electro Metallurgical Syndicate, Limited.—Registered by H. C. Bull, 29, St. George's-road, N.W., with a capital of £10,000 in £1 shares. Object: to acquire certain patents relating to the production of metals by electrolysis, and the recovery and purification of the by-products arising therefrom and apparatus therefor. Registered without special articles of association.

BUSINESS NOTES.

Burnley.—The Burnley tenders must be sent in by the 19th inst.

Windsor.—The tenders for public lighting at Windsor must be sent in by to-morrow (Saturday).

Dundee.—The Dundee Gas Commission require a travelling crane for the electric light station.

Great Northern Telegraph Company.—The receipts for the month of September were £24,000.

Ardrossan.—The contract for lighting the harbour was carried out by Messrs. Mavor and Coulson.

Bolton Tramways.—The Bolton Corporation are prepared to receive tenders for the lease of their tramways.

Telegraph Poles.—The Controller of Stores at the General Post Office requires tenders for telegraph poles by the 21st inst.

Toronto.—The electric lighting contract at Toronto expires next year, and new tenders will be invited to be sent in this month.

West India and Panama Telegraph Company.—The receipts for the half-month ended September 30 were £2,470, against £1,602.

Wimborne.—Tenders are required for lighting the public streets of Wimborne for three years, to be sent to Mr. Dibben, clerk, by 10th inst.

Eastern Telegraph Company.—The receipts for the month of September were £55,710, as against £50,789 for the corresponding period.

Grafton Galleries.—Messrs. Pyke and Harris have secured the contract for the whole of the wiring and fittings for the above galleries, in which there are 230 lights.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent payable to the London Platino-Brazilian Company, were £3,613.

Dublin.—The Dublin Corporation are expecting to make a very large revenue from their electric light station. The large business places and hotels are beginning to take it extensively.

Austrian Telephones.—The Telephone Company of Austria has declared the usual half-yearly dividend to the 30th ult. on the preference shares at the rate of 6 per cent. per annum.

Reuters.—The Directors of this Company have declared an interim dividend at the rate of 5 per cent. per annum, tax free, for the half-year ended June 30, payable on the 12th inst.

Telephone Company of Austria.—This Company has declared the usual half-yearly dividend to the 30th ult. on the preference shares at the rate of 6 per cent. per annum, payable (less income tax) forthwith.

Dolgelly.—The details of the lighting of this town show a very favourable aspect. Some 70 or 80 lamps, it will be erected at a cost less than that charged by the gas company for the same number of lights.

Belfast.—Correspondents in the Belfast papers are pressing for the introduction of the electric light in that town, and the suggestion is made that the example of St. Pancras should be taken as a model for imitation.

Middlesbrough.—At a meeting of the Electric Lighting Committee of the Middlesbrough Council on Tuesday, the sub-committee's recommendation that the Council apply for a provisional order next year was agreed to.

Chatham and Rochester.—An order for the supply of alternate-current generating plant and transformers for this station has been placed with the Brush Electrical Engineering Company.

Victoria Embankment.—Although the electric light will eventually be installed on the embankment for the County Council some time must elapse before this can be done and as additional light is required another gas lamp has been added.

Fire Alarms.—The Glasgow Police Commissioners have invited tenders for renewing and maintaining the street fire alarms and telegraph lines. Particulars of Mr. W. Paterson, chief officer of Fire Brigade, Central Fire Station, Glasgow.

Change of Partnership.—Messrs. Swinburne and Co. inform us that Lord Russell has ceased to be connected with them and that Mr. Bertram R. Beale has joined the firm, which will continue to carry on the business under the same name.

Norwich.—The Norwich Electricity Company is busily employed in putting up the buildings for the central station, and in laying the mains through the streets. Every care seems to be taken in carrying out the work, which should therefore result in complete success.

City and South London Railway Company.—The receipts for the week ending October 2 were £786, against £748 for the same period last year, or an increase of £38. The total receipts for 1892 show an increase of £883 over those for the corresponding period of 1891.

Claybury.—At the County Council meeting on Tuesday, the Asylums Committee reported that they had accepted the tender of Messrs. Latimer Clark, Muirhead, and Co. for the electric lighting of Claybury Asylum, for £15,130. The list of tenders was given on July 29.

Woolwich.—The Highways Committee of the London County Council report that the application for extension of time (six months) for a provisional order at Woolwich has been granted by the Board of Trade, and that the time for making the deposit has been extended to 5th February, 1893.

Artificial Indiarubber.—A fortune awaits the man who can make artificial indiarubber out of turpentine. *Industries* thinks the subject "well worthy of the devotion of long labour." The electrical trade certainly would be pleased, and it would not be less important to the engineering trade.

Brazilian Submarine Telegraph.—The Directors recommend a further dividend of 3s. per share, making 6 per cent. for the year ended June 30th, together with a bonus of 1s. per share. The reserve fund has been increased by £40,000, and £3,073 carried forward to the credit of the current year.

St. Pancras.—The contract for the supply of Brockie-Pell lamps for the extension of public lighting in the St. Pancras district has been placed with Messrs. Johnson and Phillips. The district to be lighted includes the Hampstead road, High street, Camden Town, and other principal streets in the neighbourhood.

Glasgow.—The Electric Lighting Committee of the Corporation of Glasgow expect to be in a position to begin supplying the new light to private consumers not later than December 1. It is further expected that the illumination of the principal streets in the central district of the city will be accomplished before the close of this year.

Birkdale (Lancs.).—At the meeting of the Birkdale Local Board, complaints having been made against the quality of the gas supplied to the district by the Southport Corporation, it was stated that a report would be submitted to the next meeting of the Board relative to the contemplated scheme of supplying the electric light.

Admiralty Boats.—We are advised by Messrs. Woodhouse and Rawson United, Limited, that they have received official notice from the Lords Commissioners of the Admiralty to the effect that their name has been placed on the Admiralty list of firms who may be called upon to tender for the construction of unarmed wood built boats and the supply of engines for the same.

Accrington.—The Accrington Town Council on Monday sanctioned a scheme for purchasing land for and erecting, at a cost of under £10,000, an electric lighting station to supply the town with electric light. The land to be secured includes the Higham Public Baths, which will be taken over by the Corporation. The Accrington Corporation have also under consideration the purchase of the gas and water works for £700,000.

Canterbury.—It is seldom that business premises get favoured like the telephone company at Canterbury, of which it was said at the last meeting of the Board of Guardians that the company had not yet been assessed. However, representatives of the four unions in the district had met and recommended that a valuer be appointed to value the company's property in the four unions, so that we expect the assessment will not now be long delayed.

Glasgow Engines.—Messrs. Lindsay, Burnet and Co., engineers, Govan, have completed the delivery and erection of the steam generating plant for the electric lighting of Glasgow. It comprises five large boilers of the marine multitubular type, built under the survey of the Board of Trade for a working pressure of 160lb. per square inch. These have all been successfully placed in the space provided for them in the basement of the new buildings erected in Waterloo street.

Wandsworth.—The committee of the London County Council reported on 5th July last, that the undertakers under the Wandsworth District and Camberwell Electric Lighting Orders, 1891, had failed to satisfy the Board of Trade of their ability to discharge their duties and obligations, and that the Board proposed to revoke the orders. Notices have since been received from the Board of Trade that the orders have been revoked as from the 25th of July and the 26th of August last respectively.

Change of Address.—Messrs. J. Sunderland and Co. have removed their works from Raven street, Halifax, to more suitable premises situated at 183, Gibbet street, and hope to have the whole of their machinery in thorough working order within the next few days. Having increased their plant they are now able to undertake any description of high-class instrument work, in addition to the ordinary patterns of telegraphic, telephonic and general signalling appliances hitherto manufactured by them.

Florence.—The new national library which is being built to contain upwards of 4,000 volumes, 380,000 pamphlets, 17,000 manuscript volumes, 950 parchments, and 190,000 autograph letters and documents in the present collection and to provide for future extension, is to be lighted throughout by electricity and will employ telephonic apparatus and, in fact, all modern aids to assist in the quick communication and delivery of works required. The ultimate capacity is for upwards of 2,000,000 volumes.

Coventry.—At the Coventry Town Council meeting last week, the Electric Light Committee reported that schemes and estimates for a central electric light station from six firms had been submitted and considered. They were from the following: Brush Electrical Engineering Company, Limited, Messrs. S. Z. de Ferranti, Limited, Messrs. Hammond and Co., Electric Power Storage Company, Limited, Electrical Construction Corporation, Limited, for Verity and Co., Messrs. J. H. Holmes and Co.

Communication with Lightships.—The statement that the Royal Commissioners to enquire into the feasibility of connecting lightships with the shore had advised that the East Goodwin lightship should be connected by telegraph wire with Dover is premature. The Commission holds its next meetings on the 18th, 19, and 20th of next month, when the report of the recent visit paid to the different lightships will be considered, and evidence will be taken from coastguard officers and masters of lightships.

Private Laboratory.—The address of Mr. Desmond FitzGerald is now 94, Loughborough-road, Brixton, and his laboratory is at 75, Akerman road, near by. The laboratory is devoted to experimental work in connection with secondary batteries, electrolytic bleaching and alkali production, as well as standard cells. Mr. FitzGerald has done much most valuable work in fields of electrical research, of which the lithanode cells are one of the most recent successes. It is to be expected that we shall hear of many other equally important advances as the result of his private laboratory.

Southampton.—The Special and General Works Committee reported the receipt of a number of tenders for the fitting of the electric light at the Corporation water works at Otterbourne, the protecting tender of Mr. Aldridge, electric engineer, being £318, 16s. 3d. Mr. Bone, in proposing the adoption of the report, stated they had received no less than 25 tenders, ranging from £398 to £227 10s., the lowest. He had had an interview with Mr. Aldridge, who recommended the acceptance of the tender of Messrs. Statter and Co., who had the contract for the electric work at the quay, for £245, and he proposed that tender be accepted, and it was accepted.

Hastings and St. Leonards.—The municipal authorities of Hastings and St. Leonards have just decided to illuminate the whole of the front line of this fashionable watering place with the electric light. At present gas and electricity are both employed to light the principal portion of the Parade, the other parts of the town being lighted only with gas. The Corporation, however, have now determined to do away with the gas altogether, and to use the electric light as the sole illuminant for the Parade, from the fish market to the end of the West Marina—a distance of three miles. This will place Hastings and St. Leonards in the enviable position of possessing what will probably be the most brilliantly-lighted sea front in the kingdom.

Whitehaven.—A correspondent to the *Whitehaven News* is in a tearing rage over the adoption of the electric light scheme. He makes several misstatements. The scheme he says, "is supported not on reason and statistics, but on hope and expectation." What is the report of their consulting engineer? The price of electricity at Newcastle, he says, "where coal is 6s. a ton, is 6d. a unit." Should it not be 4½d.? He thinks a meeting of ratepayers should be called before going on with "this gigantic scheme," which he is afraid will lead to ruin. Why does not the good man read the report of the Government enquiry, when his doubts would be set at rest? No one expects every person in Whitehaven to take the light at once. But that there is room for it is abundantly shown.

Eastbourne.—At the Eastbourne Town Council meeting on Monday, the following report from the Lighting Committee was presented: "'At a meeting, on the 20th September, a letter was read from the Assistant Secretary (Railway Department), Board of Trade, enclosing copy of correspondence which has passed between the Board and the Eastbourne Electric Light Company, Limited, with reference to the provisions of section 7 of the Eastbourne Electric Lighting Order, 1890, and enquiring if the Corporation have any observations to offer with regard to the ability of the company to perform the duties imposed upon it by the order. A statement of the company's accounts was also submitted. Resolved, 'That so far as this committee is concerned the company has performed its duties satisfactorily, and they see no reason why they should not continue to do so in the future.'"

Dundee.—The Dundee Gas Commission have issued rules regulating the applications for a supply of electric light, of which an installation is at present being introduced into the city. Along with them the charges are intimated as follows: Electric energy up to 20 Board of Trade units, 8s. 4d. per quarter; each unit above 20, 5d.; meter registering one unit per hour, 4s. per quarter, increasing gradually to 12s. 6d. per quarter for meters registering 15 units per hour. A letter has been received from the Board of Trade, in which it is stated that recent experience has shown that in the case of a system of laying mains such as that approved of for Dundee under the order for the feeder mains, in which the conductors consist of bare copper strips supported on insulators in conduits, serious damage and even danger may result from allowing any accidental contact with earth to remain in the system.

Maidstone.—The Electric Lighting Committee of the Maidstone Local Board recently met for the further consideration of the report which they presented to the Board on the 17th August, and, after discussion, adopted substantially the same recommendations as were originally made. These were as follows: "That Mr. W. C. Hawtayne be engaged to prepare the necessary plans, estimates, and specifications, and carry out the entire scheme; that Mr. Hawtayne be required to reside in Maidstone during his engagement; that he be permanently engaged to manage and start the lighting, and required to act as resident engineer in charge of the works for a period of at least 12 months after their completion; that during his engagement Mr. Hawtayne be paid a salary of £200 per annum." The cost of supplying electric light of the same illuminating power as a given gas light will, it is calculated, be about three times as much as the cost of the gas.

Pretoria.—Elsewhere we give the directors' report to the shareholders of the Pretoria Lighting Company, which seems very satisfactory. It will be within the recollection of our readers that this installation was carried out by Messrs. Crompton and Co., but it is due to that firm to state that the original system of distributing was not from their designs, but from the design of the original engineer of the company, who, we believe, has since ceased to act for the company. The contractors—and we think justly—claim great credit in that, considering the great distance of Pretoria from England, and the fact that all the machinery had to be transported by means of bullock waggons over a distance of some 170 miles up country. As will be seen from the report, the whole of the machinery has worked satisfactorily from the commencement; indeed, the directors and their engineer (Mr. Cushney) are to be congratulated upon the success of their work.

Birmingham.—The proposal is being raised to convert the Birmingham Central tramways from steam to cable roads by means of several subsidiary companies. The capital would be reduced. Mr. Ebbsmith says, with reference to the electric trams: "So far as regards the Bristol road electric line I advocate a policy of careful observation and economy, a rigid supervision of the leakages which appear at present to be inseparable from the use of secondary generators, and if possible an adjustment of salaries so that a payment by results may give every incentive to the staff employed. I should certainly deprecate any alteration or conversion until our observations have been far more lengthened, or until we are satisfied that science cannot remove the present obstacles to success." Generally, he thinks, the steam engine will have to give place to the steel rope, and that great care should be exercised in selecting the first routes. A detailed scheme is to be drawn up.

Siemens Bros. and Co.—The following interesting note appears in the report of the Building Act Committee of the County Council last week: "That the application of Messrs. Siemens Bros. and Co., Limited, for approval of plans for the construction of an iron enclosure to a proposed electromotive workshop at their premises, Bowater road, abutting upon Harrington road, be granted, upon condition that the whole of the work be executed to the satisfaction of the district surveyor, and that if the plans or application be hereafter found to be inaccurate in any particular, the approval of the Council shall be null and void. That the application of Messrs. Siemens Bros. and Co., Limited, for the consent of the Council to the erection of an electric locomotive workshop at their works, Bowater road, abutting upon Harrington road, such workshop to contain more than 216,000 but not to exceed 450,000 cubic, as shown on the plans accompanying the application, be granted, and that the solicitor do prepare the license of the Council."

Kimberley.—The *British and South African Export Journal* says of the work of Messrs. Mather and Platt at this exhibition: "This eminent firm of the Salford Iron Works, Manchester, are so well known in connection with the supply of electric lighting plant in the principal towns and mines of South Africa, that it is only natural to find them undertaking the electrical installation at the Kimberley Exhibition. The machinery employed will consist of three arc light machines of the firm's popular Manchester type. Each of these will have a capacity of 800 volts 10 amperes, and will be arranged to work 18 lamps in series. The incandescent lamps will be supplied by three dynamos, each for 100 volts 130 amperes. For the interior illumination of the building 700 16-c.p. incandescent lamps will be used. These will be provided with suspension fittings and ornamental coloured glass shades, so that the effect should be very pleasing. In the grounds there are to be 36 arc lamps of the Brockie-Pell type. These will each be of 2,000 nominal candle-power, and they will be supported upon lofty standards made by the Sectional Standards Company, Limited. A special feature of the electric lighting arrangements of the exhibition will be a powerful search light, which has been specially lent to Messrs. Mather and Platt by Messrs. R. E. Crompton and Co. It is of the Admiralty type, with a 24in. lens, and will be worked by a current of 100 amperes.

City and West-end.—Among the many contracts recently obtained by Messrs. Drake and Gorham may be mentioned the Bank of British North America, Clement's-lane; the Bank of Egypt, Old Broad-street; the London Assurance Corporation, Royal Exchange; the London residences of Lord Knutsford, 75, Eaton-square; the Hon. George Eden, 51, Cadogan-place; and Mr. J. W. Lowther, M.P., 16, Wilton-crescent. They have also obtained the contract for the wiring of the Alliance Assurance Company's offices, 1, St. James's-street, in addition to the chambers above. Several country houses are being rapidly fitted up, including Foxbury, Chislehurst, for Mr. H. H. Tiarks, where the plant will consist of two 4 h.p. nominal Otto gas engines, each driving a five unit dynamo, and there are two complete sets of cells, the whole being interchangeable. The same firm are also fitting up an installation for Mr. Swinfen Eady, Oatlands Lodge, Weybridge, where the plant will consist of a 3 h.p. nominal Otto gas engine, a three unit dynamo, and a battery of 53 accumulators. A large amount of work is also being carried out in the neighbourhood of Manchester, both plant and wiring.

London County Council.—The Highways Committee of the London County Council report that they have considered a notice dated August 8, 1892, from the London Electric Supply Corporation of intention to lay distributing mains, consisting of concentric lead-covered cables drawn into iron pipes, in Savile-row, Old Burlington-street, Cork-street, Clifford-street, and Boyle-street. They see no objection to what is proposed, and, therefore recommend that the sanction of the Council be given to the works referred to upon condition that the company give two days' notice to the Council's chief engineer before commencing the works, in the carrying out of which only one side of any thoroughfare shall be obstructed at one time; that the mains be laid under the footways, and be kept 9in. below the under side of the paving wherever it is found practicable to do so; that where the mains cross the carriageways they be kept at the same depth below the concrete or the road material as the case may be; that no street boxes shall be constructed until the positions for, and the mode of construction of, them shall have been submitted to and approved by the Council's chief engineer; that all pipes or openings from or into the boxes shall be of such shape as to remove all risk of injury to the covering of the cables; that all cables crossing the boxes shall be supported from below in the boxes; that all service lines or small cables shall be protected, where leaving the boxes, by an extra lead covering or by wooden stoppers, and shall also have a copper wire of sufficient size carried from the service to the main cable, in good connection with the lead or iron outer casting; and that the ends of all mains terminating elsewhere than in a box shall be securely protected by iron caps, in addition to any other covering. The committee have also received notice from the House-to-House Company of intention to lay mains in Penywern-road, Cranley and Drayton gardens. The mains referred to will be laid in 3in. iron pipes, and the proposed works appear to be unobjectionable. They recommend that the sanction of the Council be given to the works referred to upon condition that the company give two days' notice to the Council's chief engineer before commencing the works in any of the streets referred to in the notices; that no pipes of a larger diameter than 6in. shall be used; that the street boxes shall be of the pattern approved by the Council; and that, as an additional precaution against accident through defective insulation of the mains, each of the street boxes shall be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover shall be efficiently connected to earth. The committee further recommend the approval of notices to lay mains by the St. Pancras Vestry in cast-iron pipes, of the St. James's and Pall Mall Company, of the Metropolitan Company, of the Kensington and Knightsbridge Company, all of which are sanctioned subject to approval of the chief engineer.

Taunton.—Some fierce controversy is still going on in the *Somerset Express* over the purchase of the electric light station. Alderman Standfast has written, on his side, asking "what became of the £12,000?" and Mr. Massingham has replied, explaining. The *Express* adds a note, saying: "If Mr. Massingham will allow his brother directors to make public the figures we have asked for—i.e., the actual cost incurred in producing the electricity sold in Taunton during the last year and the actual amount paid for same—he might add the *Express* on the side of the purchasers. Until that is done we shall continue to oppose the blind purchase of what may turn out to be a bad bargain." The following information is also given in another issue of that paper: "As might have been expected, the Taunton Gas Company, as a body of ratepayers, has memorialised the Board of Trade asking that the license for electric lighting applied for by the Town Council be not granted. The memorial is signed by the chairman, vice-chairman, and secretary of the company, and the objection proceeds on the ground that the Council intend to purchase the electric works, and that said works have hitherto been carried on at a loss and would, if transferred to the ratepayers, entail a heavy burden on the town. The memorialists ask, in conclusion, that if a license be granted, that a clause should be inserted therein making it obligatory on the Town Council to charge for electric light supplied to private consumers a sum that would, at least, cover the cost of the production and the interest and other necessary expenses. A copy of the memorial has been sent to the town clerk. The electric lighting company had intended to have supplied the electricity by meter, on and after 29th September instant, but finding some difficulty in doing so they have instead revised their tariff, and will,

after the date mentioned charge a higher rate, by 2s. 9d. per annum, for every 16-c.p. light. The average price charged for 16-c.p. incandescent lights was 16s. per annum; the new price will now be 18s. 9d., or an advance of about 16 per cent. This brings the price up to about 8d. per unit, and is in accordance with the recommendation of Mr. Kapp. It was, however, in the private arc lighting that Mr. Kapp found that the principal loss was incurred, 41 private arc lamps being supplied for £410, or about £10 per lamp per annum. The charge, he contended, ought to be £22. 10s. If that advance were submitted to, it would mean something like £450 more money every year from those who use the electric light in these arc lamps. Until that price is insisted on the tradesmen who are using these lamps at the old prices are not paying cost price for their light. As regards the public lamps these pay £22. 10s., and are no loss to the company. Not only so, but there has recently been an increase made or sanctioned in the area lighted by electricity to the extent of seven lamps. For these the charge will be £157. 10s., the charge for gas lamps over the same area having been between £30 and £40. The ratepayers are thus paying some £115 per annum more for an improved street light in North Town and some other parts of the borough. This is in addition to the three or four hundred extra already paid for North-street, High-street, Fore-street, and East-street, so that the ratepayers are paying about £500 a year extra for the electric light. It is the users of these 41 private arc lamps who have been supplied under cost price at the cost of the shareholders—a loss which they are trying to shift on to the ratepayers. To this objection has been made from three distinct quarters, and the action of the Board of Trade is awaited by applicants and objectors. It is pointed out that the cost of incandescent lamps brings the price up to 6d., not 8d. per unit. Further, that though the Town Council at one time sanctioned erection of seven additional lamps, only five have been erected, and the order as to the other two has been indefinitely postponed."

Scarborough.—At a special meeting of the Scarborough Town Council, Mr. E. H. Gawne proposed the adoption of the minutes of the Sanitary and Lighting Committee, which contained a report of the Electric Lighting Sub-Committee, the principal clauses in which were that Mr. A. A. Campbell Swinton form a company to take over the powers granted to the Scarborough Corporation by their Electric Lighting Order, 1891, together with all the duties and liabilities of the Corporation under that order, such company to be formed within a period of eight weeks from October 1. The Corporation also to have the option of acquiring the undertaking at the end of 21 years upon paying for the undertaking as a going concern including the valuation of the goodwill (but without any allowance for compulsory purchase), such valuation to be made on the basis that the powers of the company would cease and determine at the end of the said thirty-second year, and upon the further basis that the dividend paid by the Company shall be taken not to have exceeded a cumulative dividend of 10 per cent.; the amount of valuation in case of dispute to be settled by arbitration. The maximum price of current to private consumers to be 7d. per Board of Trade unit. The maximum price of current to the Corporation for public lamps is to be 6d per Board of Trade unit, such price to be reduced at the rate of one farthing per unit for each £1 per cent. per annum on the cumulative dividend declared above 8 per cent per annum, after making allowance for depreciation and reserve fund, the amount to be placed to the credit of such depreciation and reserve fund respectively in any one year to be approved by the Board of Trade and not to exceed 6 per cent. on the capital for the time being expended by the company on the undertaking in the case of the depreciation fund, and 2 per cent. in the case of the reserve fund, and the total amount of such depreciation fund never to exceed so much per cent. on such capital as the electrical engineer of the Corporation shall fix, and the total amount of such reserve fund never to exceed 25 per cent. on such capital. Such depreciation fund to be used only for repairs or renewals, and in case of the undertaking being taken over by the Corporation the depreciation fund to pass and become the property of the Corporation without payment or consideration whatsoever. Councillor John Hall seconded, and went into detail on the subject of the electric lighting of the town. It would not be wise, he thought, for the Corporation to do the work themselves, but they could give it over to some company, to be hereafter formed, under the powers contained in the provisional orders that the Corporation possessed. It would be necessary if the Corporation undertook the work to secure a loan of £25,000 to £30,000 to produce the electric light. It therefore seemed to the committee that it was the wisest course to adopt to hand over the work to a company. The company would safeguard itself and would not spend more money than was absolutely necessary in laying down plant and carrying out the scheme. The Council were further safeguarded by the terms of the agreement. In addition, they would be able to take over the lighting if so desired by the arbitrator of the Local Government Board. Everything, therefore, seemed in favour of the Corporation. Councillor Edmon thought it would be better for the Corporation to undertake the work themselves. Councillor Whittaker said the company would not have a monopoly of the lighting of the borough; they would be in keen competition with the gas company. They need not, therefore, fear paying an exorbitant rate, beyond a fair percentage on the capital invested. After further discussion, during which Mr. G. T. Eaman entered a lengthened protest, the minutes were carried with but that gentleman's dissent.

Croydon.—A meeting of the Croydon County Council was held last week, when the Council decided to adopt the committee's suggestion, and retain the provisional order themselves. The General Purposes Committee's report was as follows:

When, in obedience to the desire of the Council, the sub-committee proceeded to consider the offer to take over the powers contained in the Corporation Electric Lighting Order as referred to in paragraph 4 of the last report of the committee, it appeared to the sub-committee desirable that the Council should, when particulars of this offer were presented, also know what other offers, if any, could be obtained. The sub-committee therefore caused advertisements to be issued inviting tenders. As the result of these advertisements five proposals have been received, of which the particulars will be found below in sub-paragraphs *b*, *c*, *d*, *e*, and *f*. Sub paragraph *a* contains the particulars of the offer mentioned in paragraph 4 of the last report and above referred to.

Offer A.—(*a*) It is proposed to form a local company to take a transfer of the provisional order, and carry out and establish a central station, it being stipulated that within seven days of the Council agreeing to transfer the provisional order, the erection of a central station should be proceeded with. If it should become desirable later on to erect other stations in other parts of the borough, the company would, it is stated, be ready to meet all requirements. The Corporation to have the option, after seven years and within 15 years from 1890, to purchase the undertaking at a price equivalent to the capital expenditure properly incurred with an addition of 33 per cent. thereto.

Offer B.—(*b*) To take a transfer of the provisional order, and to construct an electric lighting station on the high-tension alternating system. The Corporation to provide at a nominal rent a site for the erection of a station. The contractors to pay to the Corporation the costs of obtaining the provisional order, and to give an option to the Corporation to purchase the undertaking at the end of 21 years, or any succeeding five years upon the same terms as are provided by the Electric Lighting Act for the purchase of an undertaking at the end of 42 years.

Offer C.—(*c*) To form a local company to take a transfer of the provisional order, and to carry out electric lighting thereunder upon such system as may be determined. The Corporation to enter into a contract with the company for the electric lighting of the main thoroughfares upon terms to be agreed. The Corporation to undertake not to consent to to another provisional order or license during the continuance of the agreement. The price of electricity to be reduced one farthing per Board of Trade unit for each 1 per cent. made beyond a cumulative profit of 10 per cent. after allowing for depreciation and for a reserve fund. The Corporation to have the option at the end of 21 years, and each subsequent 10 years, of paying therefor as a going concern, including valuation of the goodwill.

Offer D.—(*d*) A local company to take a transfer of the provisional order, and to carry the same out upon the moderate high-tension system, combined with the most recent improvement of low-tension distribution from sub-stations. The maximum price of electricity to be 8d. per unit. The Corporation to have the option, upon six months' notice, to purchase the undertaking upon the following conditions: I. Up to 1902 by issuing to the company such an amount of Corporation stock as will produce an annuity of 4½ per cent. per annum upon the capital expended upon the works, and also upon payment to the company of such sum as will, together with the dividends paid, amount to 5 per cent. per annum upon the paid up capital to the date of completion of the purchase. II. Between 1902 and 1912 by issuing to the company such an amount of Corporation stock as will produce an annuity of 4½ per cent. per annum upon the capital expended on account of the undertaking. III. Between 1912 and 1922, either upon the terms of II. or upon payment of the then value of the undertaking according to section II. of the Electric Lighting Act of 1888, together with the value of the goodwill to be settled by arbitration. IV. On December 31, 1922, or at expiration of any seven years thereafter, either upon the terms of II. or upon payment of the then value of the undertaking in accordance with section II. of the Electric Lighting Act, 1888.

Offer E.—(*e*) To form a local company to take a transfer of the provisional order, and establish a central station at an estimated cost of £20 000. To raise a capital of £25,000, and to pay the Corporation a bonus of 5 per cent. thereon—viz., £1,250. The balance of the £25,000 would, it is expected, be absorbed by the expense of forming the company and issuing the capital. The Corporation to have the option to purchase the undertaking on payment of £25,000 for the first installation, as well as all moneys actually expended upon subsequent installation, and in addition five years' purchase of the average annual next profits during the three years previous to the exercise of the option. Such average net profits to be ascertained by taking the dividends actually paid, and any reserve, depreciation, or sinking funds to remain the property of the company.

Offer F.—(*f*) To take a transfer of the provisional order, and to give the Corporation the option of purchasing the undertaking at any time during the continuance of the order at a price consisting of the capital expended on the undertaking, and a sum equal with dividends earned to 7½ per cent. per annum upon the investment from the commencement of the order, the contractors undertaking to supply electric current for the public street lamps at cost price.

Copies of the several offers referred to may be seen at the town clerk's office. The Council will observe that under either of the above-quoted offers, if the Corporation should desire to repurchase the undertaking, they will have to pay a substantial profit upon the sum actually expended by the contractors, and they may find themselves in the position of having to take over a considerable amount of plant which at the time of purchase may be out of date and of little value, but which the Corporation will have to acquire, not at its then value, but at a considerable premium on its original

cost. In the event, too, of the Corporation desiring to purchase the undertaking, questions will certainly arise as to what should be deemed to have been a proper expenditure of capital, and disputes may ensue, the settlement of which will involve considerable expense. The transfer of the powers of the Corporation will involve the interference, by a company, with many roads and footpaths in the borough, the entire control over which it would be far better should remain in the hands of the Council. It will be observed that four of the offers made involve the formation of local companies, and it is probably contemplated by those from whom the offers proceed that some portion of the capital will be locally subscribed. As to this there may be some difficulty, and, although in case of offer "A" a guarantee is given that the erection of a central station would be immediately proceeded with, yet any failure to obtain local capital would probably lead to considerable disappointment, and possibly result in some delay in completing the installation. The Corporation, it is certain, will be large consumers of electricity for the new municipal buildings and library, and eventually consumers on a very large scale for street lighting. Many of the corporations which have obtained electric lighting powers within the last two or three years have now determined to keep those powers in their own hands. The following figures show the result, to a recent date, of the introduction of electricity into Bradford, where the Corporation have undertaken the electric lighting of the town:

		No. of lamps fixed.	Total receipts	Total expenses.
1890.	June 30	4,000	£858	£898
,,	Dec. 31	6,880	1,552	1,174
1891.	June 30	8,500	2,093	1,261
,,	Dec. 31	13,436	3,592	1,591

Taking all these circumstances into consideration, the committee recommend that the Council should determine to carry out the powers of the provisional order itself, either now or at a future date, the committee being authorised to ascertain and report what additional expenditure would be involved by the installation and plant for lighting the new Town Hall and library, being of sufficient capacity also to supply consumers within the compulsory area, and being designed with a view to future extensions. This information will enable the Council to determine whether it would be wise to carry out the powers of the provisional order at once, or for the present to confine the operations to the new buildings.

PROVISIONAL PATENTS, 1892.

SEPTEMBER 26.

17151. **Improved "wall," "table," or floor connection for portable electric lamps.** Andreas Peter Lundberg, 18, Regina-road, Tollington-park, London.

17160. **Improvements in telephone switchboard apparatus.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.)

17169. **Improvements in or relating to the electrolytical decomposition of metallic salts and in apparatus therefor.** Charles Kellner, 46, Lincoln's-inn-fields, London.

SEPTEMBER 27.

17206. **Continuous electric current machines and motors.** William Aldred, 5, Brightside-bank, Brightside, Sheffield.

17207. **An improved ear piece for telephones.** Thomas Johnstone, 27, Kirkgate, Bradford.

17209. **Improvements in the slides of electric sliding pendants.** Robert Hall Best, Cambray Works, Handsworth, Birmingham.

17222. **Improvements in or relating to electric metal working or welding.** William Philips Thompson, 6, Lord-street, Liverpool. (Charles L. Coffin, United States.) (Complete specification.)

17223. **Improvements in or relating to welding or working metals electrically.** William Philips Thompson, 6, Lord-street, Liverpool. (Charles L. Coffin, United States.) (Complete specification.)

17224. **Improvements in apparatus for electrically heating and working metal.** William Philips Thompson, 6, Lord-street, Liverpool. (Charles L. Coffin, United States.) (Complete specification.)

17225. **Improvements in the method of and apparatus for electrically welding metals.** William Philips Thompson, 6, Lord-street, Liverpool. (Charles L. Coffin, United States.) (Complete specification.)

17226. **Improvements in the method of and apparatus for welding or heating metals electrically.** William Philips Thompson, 6, Lord-street, Liverpool. (Charles L. Coffin, United States.) (Complete specification.)

17227. **Improvements in or relating to electrically welding or heating metals.** William Philips Thompson, 6, Lord-street, Liverpool. (Charles L. Coffin, United States.) (Complete specification.)

17242. **Improvements in electro-medical appliances.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, London. (Sophia Hetherington, Arrataers, New South Wales.) (Complete specification.)

17244. **Improvements in or relating to the supply of electricity to electrically propelled and controlled aerial machines.** Charles Camlonga, 46, Lincoln's-inn-fields, London.

17246. **Improvements in or connected with electric primary batteries.** Thomas Joseph Davies Rawlins, 1, Quality-court, Chancery-lane, London.

SEPTEMBER 28.

17287. **A new or improved shield or cover for electric gas lighting purposes.** Joseph Hamer, Commercial-street, Halifax.

17299. **Apparatus for the inhalation of metals or minerals vapourised by means of electricity for medical, antiseptic, or other purposes.** Edmund Savary d'Odiardi and Eva Savary d'Odiardi, 55, Cornwall-gardens, London.

17320. **Improvements in electric heaters.** Thomas Ahearn, P.O. Box 1,071, Ottawa, Canada. (Complete specification.)

17321. **Improvements in electric water heaters.** Thomas Ahearn, P.O. Box 1,071, Ottawa, Canada. (Complete specification.)

SEPTEMBER 29.

17381. **Improvements in and relating to telephonic instruments.** James Muirhead, 96, Buchanan-street, Glasgow.

17423. **Improvements in apparatus for supplying electricity to electrically-propelled vehicles.** Emile Chabeault, 46, Lincoln's-inn-fields, London.

SEPTEMBER 30.

17462. **Improvements in and apparatus for moulding earthenware electric switches, ceiling roses, bell pushes, and the like, and forming screw threads thereon.** Joseph Mier, 55, Market-street, Manchester. (Complete specification.)

17466. **An improved electro metallurgical process.** Henry Clay Bull and Gustavus Baron de Overbeck, 15, Water-street, Liverpool.

17467. **Improvements in driving sewing machines by electricity.** Henry Lee, 7, Staple inn, London.

17471. **Improvements in electrical motor and fan combined for filtering and fumigating the air.** Samuel Coxeter and Henry Nehmer, 4, Grafton-street, Gower-street, London.

OCTOBER 1.

17491. **Improvements in the application of electricity to the human body.** John Stevenson, Norwood Lodge, Middlesbrough.

17494. **Electric indicator and apparatus for cooling any part of machinery which may become heated by friction.** Hugh W. Horne, 5, Causeway side, Edinburgh.

17504. **Improved operating electric switch.** David Loch, 55, Calvert road, East Greenwich, London.

17509. **Improvements in the construction of field magnets of dynamo-electric generators.** Thomas Reginald Andrew and Thomas Preece, 20, Charles-street, Bradford.

SPECIFICATIONS PUBLISHED.

1891.

15414. **Electric lamps.** Kelway.

17192. **Electric distribution.** Wright.

18595. **Electric motors.** Harrison and Budd.

19196. **Electric lamps.** New.

19450. **Electric apparatus.** Marsh and others.

19852. **Magnetic separators.** Hoffman.

22025. **Electric light fittings.** Smallwood.

1892.

1436. **Dynamo-electric, etc., machinery.** Johnson. (De Bovet.)

13562. **Electrical accumulators.** Young. (Colgate.)

14189. **Distributing electric currents.** Lake. (Stanley and another.)

NOTES.

Wolverhampton.—A site has been selected for the central station in Wolverhampton.

Paris.—Baron de Pfeffel succeeds M. Victor Popp as managing director of the Paris Compressed Air Company.

Death of Tennyson.—Lord Kelvin was one of the band of eminent pall-bearers at the funeral of Tennyson, at Westminster Abbey, on Wednesday.

Antwerp Exhibition.—The Superior Industrial Council at a meeting in Brussels on Wednesday decided that an international exhibition should be held at Antwerp next year.

Search Lights. — A 50,000-c.p. search-light is to be placed on the statue of Liberty in New York. It is to be similar to that at Mount Washington, and will be visible 100 miles.

Cheap Electric Motor. — The *Scientific American* describes in a recent number a new simple but efficient motor, placed on the market at the ridiculously low sum of four shillings.

Technical Schools.—A technical school is to be erected at Bridgend, Glamorganshire. The Radcliffe Technical Instruction Committee intend to erect a school at a cost of £3,000.

Lamp Rate.—It is stated that an influential section of Bradford inhabitants, afraid of the advances of electricity, are proposing a small "lamp rate" to meet any loss on the gas, instead of raising the price.

Colonial Telegraphs.—A circular is being sent to all the chambers of commerce with reference to a proposed new cable between Canada and Australia. The Associated Chamber is expecting to take up the question shortly.

Aluminium.—The soldering of aluminium, which has long been a difficult problem, has been recently solved. By sprinkling the surface to be soldered with chloride of silver, and melting down, the soldering is effected simply and satisfactorily.

Cheltenham.—Mr. Norman, in proposing the adoption of the minutes of the Cheltenham Electric Lighting Committee, said an arrangement had been made with Prof. Ayrton to confer with him and inspect the St. Pancras and other lighting systems.

Sweden.—It is pleasant to see that Niagara, Rheinfelden, and the Tivoli falls are not to have an exclusive utilisation of large water powers. In Sweden, for instance, the great Trollhatta waterfall, near Gothenburg, is to be utilised to the amount of 6,000 h.p.

Nottingham Goose Fair.—A noticeable feature of the great goose fair at Nottingham last week, says a correspondent, was the fine effect of the combined electric and gas lights on the central area, which bathed the concourse in silvern and golden hues.

Tudor Accumulators. — The Société Anonyme Franco Belge, which manufactures Tudor accumulators, has opened a laboratory and office for dealing with installations using accumulators, at 19, Rue de Rocroy, Paris. M. Priaux is their engineer.

Birmingham.—A site containing 2,846 square yards of land has been selected in Commercial road, Birmingham, for the central electric station, the cost being £1,900. The Finance Committee are to be authorised to raise Corporation stock to erect the plant.

Domestic Electric Lighting.—Messrs. H. Alabaster, Gatehouse, and Co. have now in the press, shortly to be issued, a new work, entitled "Domestic Electric Lighting, Treated from the Consumer's Standpoint." The author is Mr. Ed. C. de Segundo, A.M.Inst.C.E.

Paris.—In Paris, out of 85,000 houses, there are only 20,000 lighted with gas, whereas 175,000 electric lamps are in use. At present the plant at the municipal central station can keep 96,000 lamps constantly lighted, and the generating power will soon be doubled.

Middlesbrough.—The chairman of the Middlesbrough Electric Lighting Committee thinks it would be the height of folly to introduce the electric light at the expense of the ratepayers. An order is to be obtained to enable the Council to hold their ground for a year or two.

Calorimeter.—A delicate calorimeter was recently described by Messrs. J. A. Harker and P. J. Hartog at Edinburgh. This is essentially a Bunsen ice calorimeter, with solid acetic acid instead of ice, so being much more delicate, and capable of being used at ordinary temperatures.

Macclesfield.—The first introduction of electric light into Macclesfield has been carried out by Mr. W. R. Brown. The dynamo is driven by a 5-h.p. Tangye gas engine, a 3,500-watt Elwell-Parker dynamo being used. The shop is lighted by 32-c.p. lamps, and the windows have 200-c.p. lamps.

Albert Palace.—Mr. John Burns has announced that an anonymous donor has promised £10,000 for the proposed Albert Polytechnic for South London if the Vestry and the Charity Commissioners make up a similar sum. The Vestry are to hold a special meeting to consider this munificent offer.

Bradford.—The Markets and Fairs Committee recommended to the Council the acceptance of the tender of Messrs. Andrews and Preece for supplying and fixing the necessary fittings for lighting Kirkgate Market by electricity. The amount of the tender is £1,440. The recommendation was adopted.

Electricity in Harvest.—The Rev. G. B. Stone, preaching at St. Thomas's, Garstang, at the harvest festival, gave credit to the steamboats, telegraphs, and telephones for their share in the success of the cereal supplies of England, and hinted at still greater developments of the use of electricity in harvesting.

Accumulator Traction.—MM. Huber and Magée have recently developed a system of electric traction, entitled an improved method of electric locomotion by direct intermittent feeding by secondary batteries. The method is stated to be eminently practical, and further details are obtainable of M. Barrault, 58, Chaussée D'Antin, Paris.

Telephone from Liverpool to Llanwddyn.—A committee of the Llangollen District Board has been appointed to superintend the laying down of 24 telephone poles along the roads in the townships of Lledron and Lloran Isa in connection with the project of the Liverpool Corporation to establish a communication between that city and the Vyrnwy Water Works.

Plymouth.—The gas company at Plymouth seem to have been making great improvements in the public lighting recently by the introduction of new burners. Mr. Bazley, speaking at a ratepayers' meeting, said it was hoped that the gas company had at length realised the fact that the only way to stave off the electric light was to see that the gas supplied was of the best quality.

Kingswood.—Attending the Kingswood Local Board last week, Mr. Parfitt, representing the electric light company, explained that the limited light which had been complained of was due to the lamps. The company intended to put new lamps at once, which would remedy

this. The cause of the lights going out one night was due to lightning puncturing their insulation in several places.

Provincial People's Palaces.—A handsome and spacious building has been opened at Glusburn, Crosshills, Craven, near Keighley, being the gift of Mr. J. C. Horsfall, C.C., to be used as a "people's palace" and technical institute. Mr. Horsfall has simultaneously closed The Red Lion Inn, of which he was owner, to induce the younger generation to spend their time more advantageously than at the public-house.

Dividends.—The *Gas World* points out that the high dividends of the private companies, like the Brush, may be ascribed to the fact that trade is bad—not because it is good. For the municipality can take advantage of a dull period to borrow money cheaply and embark in electric lighting. It adds, the Brush Company having already shared profits with those receiving monthly salaries, now intends to bring in the wage-earners also.

Endowment of Research.—Sir James Crichton-Browne, treasurer of the Royal Institution of Great Britain, has received from Mr. Thomas Hodgkins, of Setanket, Long Island, New York, a donation of £20,000 to the funds of the institution, to be applied in promotion of scientific research. Mr. Hodgkins recently presented £40,000 to the Smithtonian Institution at Washington. The idea is spreading in some quarters that the giver really meant to endow the Royal Society.

Manchester Association of Engineers.—A paper with an interesting title is to be read before the Manchester Association of Engineers on November 12, by Mr. B. H. Thwaite, of Liverpool. It is on "Economic Possibilities of the Generation of E.M.F. in the Coalfields and Its Application to Industrial Centres." Before the same association on March 11 next year, Mr. C. R. Iorns is down for a paper "On the Relations between Employers and Workmen in Engineering Works."

Electric Traction Finance.—Sir J. Whittaker Ellis is understood to be visiting America with the express object of inspecting the various systems of electric street railways in the States, with the intention of giving attention to the financing of important schemes in this country. Mr. Steinway, the eminent pianoforte maker, of New York, is in London, it is stated, with the same laudable desire to give Britain the advantage of financial support to the long-tarrying schemes for rapid electric locomotion.

Feed-Water.—Researches made by Prof. Lewis, of the Royal Naval College, more particularly as to marine boilers, on the burning of boilers, demonstrated that collapse is often due to the presence of oil or grease in the feed-water. Mr. J. B. Edmiston, of Liverpool, has devised a filter of flannel and wire cloth to cleanse the feed-water previous to injection, and an inspection of one of these filters after use shows their usefulness in stopping impurities. The feed-water filter has already been applied to many boilers.

Electric Fishing.—Experiments have recently been made in the Toulon Roads for illuminating the bottom of the sea with electric lamps. The whole apparatus, weighing 132lb., was sunk in six fathoms, and illuminated the bottom to a radius of nearly 100ft. An immense quantity of fish were attracted—so much so that the idea was expressed that it would contribute to the wholesale destruction of fish resorts on the coast. The lamp is thought likely to afford the greatest service for surveying wrecks or reconnoitring for submarine mines.

American Roads.—The wretched condition of the roads in most towns in America is one of the first observations of the traveller. If we have much to learn from their great progress in electric traction, they have more to learn in the construction of ordinary roads. Indeed, the well-known disinclination of Americans to walk and the progress of mechanical means of traction is probably largely due to their bad roadways. It is interesting to learn that an attempt is being made to have a comprehensive exhibit of roads and roadmaking at the Chicago Exhibition.

Popular Electricity in France.—The spread of interest in electricity has led to the establishment in all countries of a number of new electrical papers, amongst which, in France, we notice one under the expressive title *Electricité pour Tous* (Electricity for All), issued at the modest price of 15c., or 1½d. It is an eight-page fortnightly, containing articles on batteries and so forth, and current notes, not too highly scientific, of electrical progress, with cuttings on general electrical items. It may be made into a bright and popular technical paper.

Mining in Malay.—The first ordinary meeting of the second session of the Institution of Mining and Metallurgy, London, will be held on the evening of Wednesday, 19th inst., in the lecture theatre of the Geological Museum, Jermyn street, S.W. (the use of which has been kindly granted by the Lords of the Committee of Council on Education), at 8 o'clock. After an address by the president a discussion will be held on the paper on "Mining in the Malay Peninsula: a Field for Mechanical Appliances, Hydraulic and Electrical Transmission and Power," read by H. M. Becher, Esq. (member), on June 15.

Odylic Force.—We have often to call attention to absurd statements in the newspapers on electrical matters. The provincial papers are the worst offenders, though the London papers are not immaculate. Not enough is the puffing of electropathic boots or whatnot, but we must actually have electric control of the weather. According to a note that has been going the rounds, a Mr. John Collinson, "of London," claims the gift of being able to control the elements by "odylic force," discovered 20 years ago—a crystal "acting as a magnet on a sensitive" is to still winds and waves. The most extraordinary part is that he can get responsible editors to suggest in good faith that the Agricultural Department, Lloyd's, and others, might do well to appoint a committee of 12 to investigate these ridiculous pretensions.

Accumulators.—Captain Khotinsky, writing in our namesake in America, points to a condition to which attention has been called before, but which should be consistently kept under notice. He says: "In experimenting with one cell filled with well-mixed 10 per cent. solution of acid, after a few successive charges and discharges, I found that the specific gravity of the acid in a charged cell changed so that in the upper part 2½ per cent. and at the bottom 30 per cent. of acid was found in solution. From this confirmed fact it follows that the lower part of a plate must be sooner destroyed by extra work imposed on it by the stronger acid and by the same agency in the lower part. The internal resistance is reduced, while in the upper part of the plate, by reason of the lighter acid, the opposite occurs, and the internal resistance is therefore increased."

Electro-Metallurgy.—Those who were fortunate enough to attend Mr. J. Wilson Swan's lecture on "Electro-Metallurgy" at the Royal Institution, or to inspect the apparatus afterwards shown privately in his laboratory at Bromley, will have at once recognised the great practical importance that will be likely to accrue from the adoption of the methods of quick copper deposition there explained and demonstrated. We are pleased to notice that these experiments have attracted attention in the great centre of metallurgy—Birmingham—and in the forthcoming Midland

Institute lectures, for which many of the most eminent men of the time are engaged in their special subjects in science or literature, Mr. Swan's name is down for a lecture on "Electro-Metallurgy." The occasion will be of great interest to the manufacturers and scientific men of that city, and we notice that Messrs. Elkington, the well-known electroplaters, who were first in the field to utilise Faraday's discoveries, will have their interesting collection of apparatus on view at this lecture.

Electric Fireworks.—The electric light is becoming an acknowledged accessory of fireworks on the occasion of fêtes. For instance, the good ship "Ravenswood," which is wont to ply for excursions up the Bristol Channel, took her farewell trip for the season last week along the Somerset coast to Clevedon. As it was known that fireworks and other special attractions were to be provided on board, there was a very large number of passengers, and the quay wall at Bristol was lined with people who had come down to see the vessel start. After passing the Suspension Bridge coloured lights were burnt from the stern of the boat, and directly afterwards a searchlight which had been fitted up astern was turned on. The search light, which had been supplied by Messrs. King, Mendham, and Co., and was of the type used in the Royal Navy, was fitted with an arc lamp of about 5,000 c.p., with reflector and glass lens in front of the lamp. The current was supplied by the dynamo that provides the electric light to the ship. The light was worked by Mr. A Rouch, superintendent electrician to the firm above mentioned, and caused great amusement when suddenly flashed on various objects during the journey down the river.

St. Pancras. At the meeting of the St. Pancras Vestry on Wednesday, Mr. A. Sweet, chairman of the Electricity Committee, stated that no rate whatever would be required to be levied in respect of electric lighting purposes. It was further stated that High-street, Camden Town, would be illuminated with arc lamps on high iron columns, in a similar way to Euston road and Tottenham Court road. The committee, having inspected the arc lamps of various makers, and considered their respective merits, were of opinion that the arc lamp (the Brockie Pell), now in use in the parish was, at this period, the best lamp that could be adopted for street lighting. Applications for the electric current had been received from residents on the west side of Gordon square, and it was decided to lay a main for the purpose of supplying the desired current. Mr. N. Robinson, one of the members of the London County Council, asked Mr. Sweet whether the electric system adopted in the parish was a financial success and likely to pay its way. Mr. Sweet replied that so far from the electric system having proved a failure financially, he was surprised that so large an undertaking should have been carried out without the necessity of any rate whatever. Already they had more orders for the electric current than they could supply with their existing station. There was not the least doubt that the present installation would pay. Answering Dr. Bell, Mr. Sweet said, "Of course the Vestry were supplying electricity at a profit."

Hull Tramways.—Some little time ago it was announced that the Hull tramways were to be leased to a London syndicate, who would institute electric tramcars. We communicated with the authorities, and were given to understand there was no truth in the statement, but it seems there must have been, for the Works Committee at their last meeting submitted a scheme for the purchase of the tramway systems in Hull, construction of the same with double lines, and the leasing of them to a London syndicate, to be run by electricity. There were several objections to the details of the scheme, and after a long discussion, a motion for the adjournment of the debate until after the November elections was lost, and a resolution come to to discuss the objections. The period of the lease, 30 years, was objected to by Alderman Leak, who thought that the Corporation should have the option of taking over the system at the end of 14 years. Mr. Pool thought that the proposal to hand the trams over to a company was one of the greatest blunders that the Corporation ever made. In five years every man in that Council would be in favour of getting the trams. If they were to poll the town they would find the majority of the people in favour of their municipalisation. Motions to make the lease terminable at seven or fourteen years were lost. Several other points of detail were agreed upon, and Mr. Russell moved an amendment to the whole proposal, that the Council should adopt the principle of the Corporation making and conducting their own tramway system, but it was lost, and the minutes were passed.

Gilt Lead Accumulator Strips.—The important experiments of Mr. Desmond FitzGerald on the sulphating of lead plates, which led to his invention of gilt lead strips, do not seem to have received the attention they deserve. These experiments, which are described in his patent, can be briefly described. He found that when a strip of lead was placed in contact with peroxide of lead, the active material could be charged by this contact without bad effects developing, but that when the active material was discharged a slight layer of sulphate was always formed, which eventually stopped the action. The second experiment was that when the lead strip was coated by a layer of gilt, however thin, the action of both charge and discharge could go on without any sulphating occurring. This experiment throws an important light upon the theory of the ordinary accumulator. The difference between the FitzGerald experiment and the charge and discharge of an ordinary accumulator seems to be evidently merely one of size of lead surface in contact with active peroxide. The contact surface is very much larger in the case of the ordinary accumulator, but every time the plates are discharged sulphating must occur, and every time this sulphating has to be reduced again. This action eventually destroys the so-called "positive plate." The practical conclusion is that the present system requires an enormous surface of lead to prevent noticeable sulphating, but with gilt lead supports, as proposed by Mr. FitzGerald, the extent of lead surface can be very greatly diminished, and the destruction of the "positive" is stopped. The discovery of the practical method of gilding the lead strips cost Mr. FitzGerald four months of experimental research.

Meters. The case of Bath will very clearly demonstrate the necessity of meters to a supply company. Until recently the electric light in Bath was supplied by contract at a fixed sum per burner per annum, as did the early gas companies. Since there are now several meters which, although not perfect, are sufficiently accurate for ordinary purposes, it has been decided to introduce the system of charging by meter. It is an indication of the greater call for accuracy on the part of electrical engineers, that meters which would pass the gas standard in percentage of error are not sufficiently accurate to be certified by the Board of Trade. Indeed, only one type by one manufacturer, the Shallenberger, has the sanction of the Board of Trade, and this is not to be extended to other manufacturers. No other meter has yet absolutely come up to requirements, it appears, and though there is nothing to prevent companies using that meter which is most accurate, yet until the meters are actually passed, and until a legal standard of current has been adopted, the amount of current sold cannot legally be sued for,

except under agreement to take such and such a meter as correct. Meters, however, are being very widely used with satisfactory results, and the legalisation of the unit cannot be very long in coming. The dissatisfaction of the contract system is twofold, both with him who gives and him who receives—the company and the consumer. For the absence of meter leads to waste of current, and the persons who shut up shop at an early hour, or even 7 p.m., feel they are paying a higher price for the light than the hotels, clubs, and other consumers who keep their light going till midnight. There are several exceedingly good meters on the market, and we hear great things are being said of a meter we described some year or so ago, made by a firm in the North of England, which is to be adopted in an important central station shortly to be started. For all sakes, it is to be hoped the Board of Trade will obtain their legalisation, as they expect, before Parliament meets. Some wonderfully close agreements have been made with the Board's apparatus and the best German standards, and the French electricians are understood to intend to adopt the British legal unit.

Electro-Therapeutics.—We referred in our last issue, p. 348, to an article in our contemporary *Trade, Finance, and Recreation*, and stated that the concluding portion of the article would appear in a subsequent issue of that paper. We have the conclusion before us, and the author of this article very kindly sums up his conclusions, which are (1) that the Harness electropathic belts do generate current; (2) that these currents penetrate the skin; and (3) that the currents in question approximate very closely in strength with homo-electric currents. We must confess still to a lack of conviction. We will not object to the first conclusion, and we do not think that anyone else objects to it. With regard to the second we are at a loss to know how these currents manage to penetrate the skin; and thirdly, we do not quite understand the author's meaning of homo electric currents, nor are we quite sure from his experiments that he ought to designate the currents causing the deflection of his galvanometer as homo-electric currents. It is probably an open secret to some of us that the author of these articles has had an extensive experience in electrical matters, and that the questions which he here discusses have been more or less discussed verbally. In the experiments he describes there are two electric phenomena under consideration, or perhaps three—the body looked upon as a generator, as a conductor, and as a condenser. Had the author been satisfied with merely describing his experiments, and not connecting them in any way with Harness's electropathic belt, more attention would probably have been given to them. We venture to think, however, that this is a mistake, and that the very connection between these experiments and the belts should lead to a closer investigation of what the author says, when probably it will be found that though a repetition of the experiments leads to similar results the interpretation of the causes may be totally different. For some time past we have been endeavouring to arrange for a repetition of the experiments, but, as most people know, when several people are interested in a matter it is difficult to get a meeting at a particular time. We shall therefore leave further comments until we have gone through the whole series of the experiments as described. Any reader who has the use of a sensitive galvanometer can easily conduct the experiments. It would be perhaps satisfactory if a number of them did so, in order to get conclusive evidence on one side or the other.

Fire Risks.—It is fashionable amongst a certain class of electrical engineers to say that fire insurance companies do little but throw obstacles in the way. Speaking in this way is but giving vent to random words and vilifying an important and honourable body of men who are seeking to do their duty to themselves and the public. The more reasonable process would have been, what might still be done with advantage, for these selfsame electrical engineers or others to write a fair and straightforward account of what they considered the duties of an insurance office from their standpoint, with full and sufficient details of electrical work to render the technical knowledge necessary to pass good work easy of attainment. The organ of the fire offices, the *Review*, in the issue of Oct. 5th, takes up the question of electric installation risk in an eminently reasonable spirit. "Slowly but surely a corps of trained surveyors has been formed," says this paper, "*who by practice* are rapidly acquiring a knowledge of the various points involved, and of how many specific dangers revealed can be avoided; but we would warn both the public and the fire offices, that infinitely more depends upon the reputation of the firms engaged in laying on the installation than any survey, however close and searching. If fire surveyors had to test personally each section of every installation put up, it would mean an incredible amount of time and trouble being devoted to the subject. What is really wanted is the formation of a corps of scientific electricians, who shall, at the request of the fire offices, give independent certificates, without knowing or caring for the interests of either the electric firms interested or the fire insurance companies. It shall be their duty to test every apparatus, from the installation of the dynamo up to the last switch. They should not merely have the power, but they absolutely should lift the casing at all joints and test the diameter of the wires. They should require to be furnished with a sample of all the wires laid on, with a statement attached to each wire of the circuit on which it is used, and the power and capacity of the lamps thereon. Switches, fuses, and circuits should be numbered, and samples of the wires and fuses used stuck on a sheet of cardboard; the whole work on a moderate installation would, on such a system as this, not take half a day to accomplish." The *Review* intends to deal more fully with the technical aspect of the case, and it will be very well worth the while of those engineers whose interests are at stake on this question to watch the discussion which will ensue. The statement is added at the close of a thoughtful article that "we are deliberately of the opinion that a properly executed low-tension installation of the electric light is infinitely safer than gas, and most immeasurably better than any kind of lighting by means of lamps or candles." It is hoped the means will be found and regularly administered to protect the safety of the householder, and avoid all extra risk to the insurance companies.

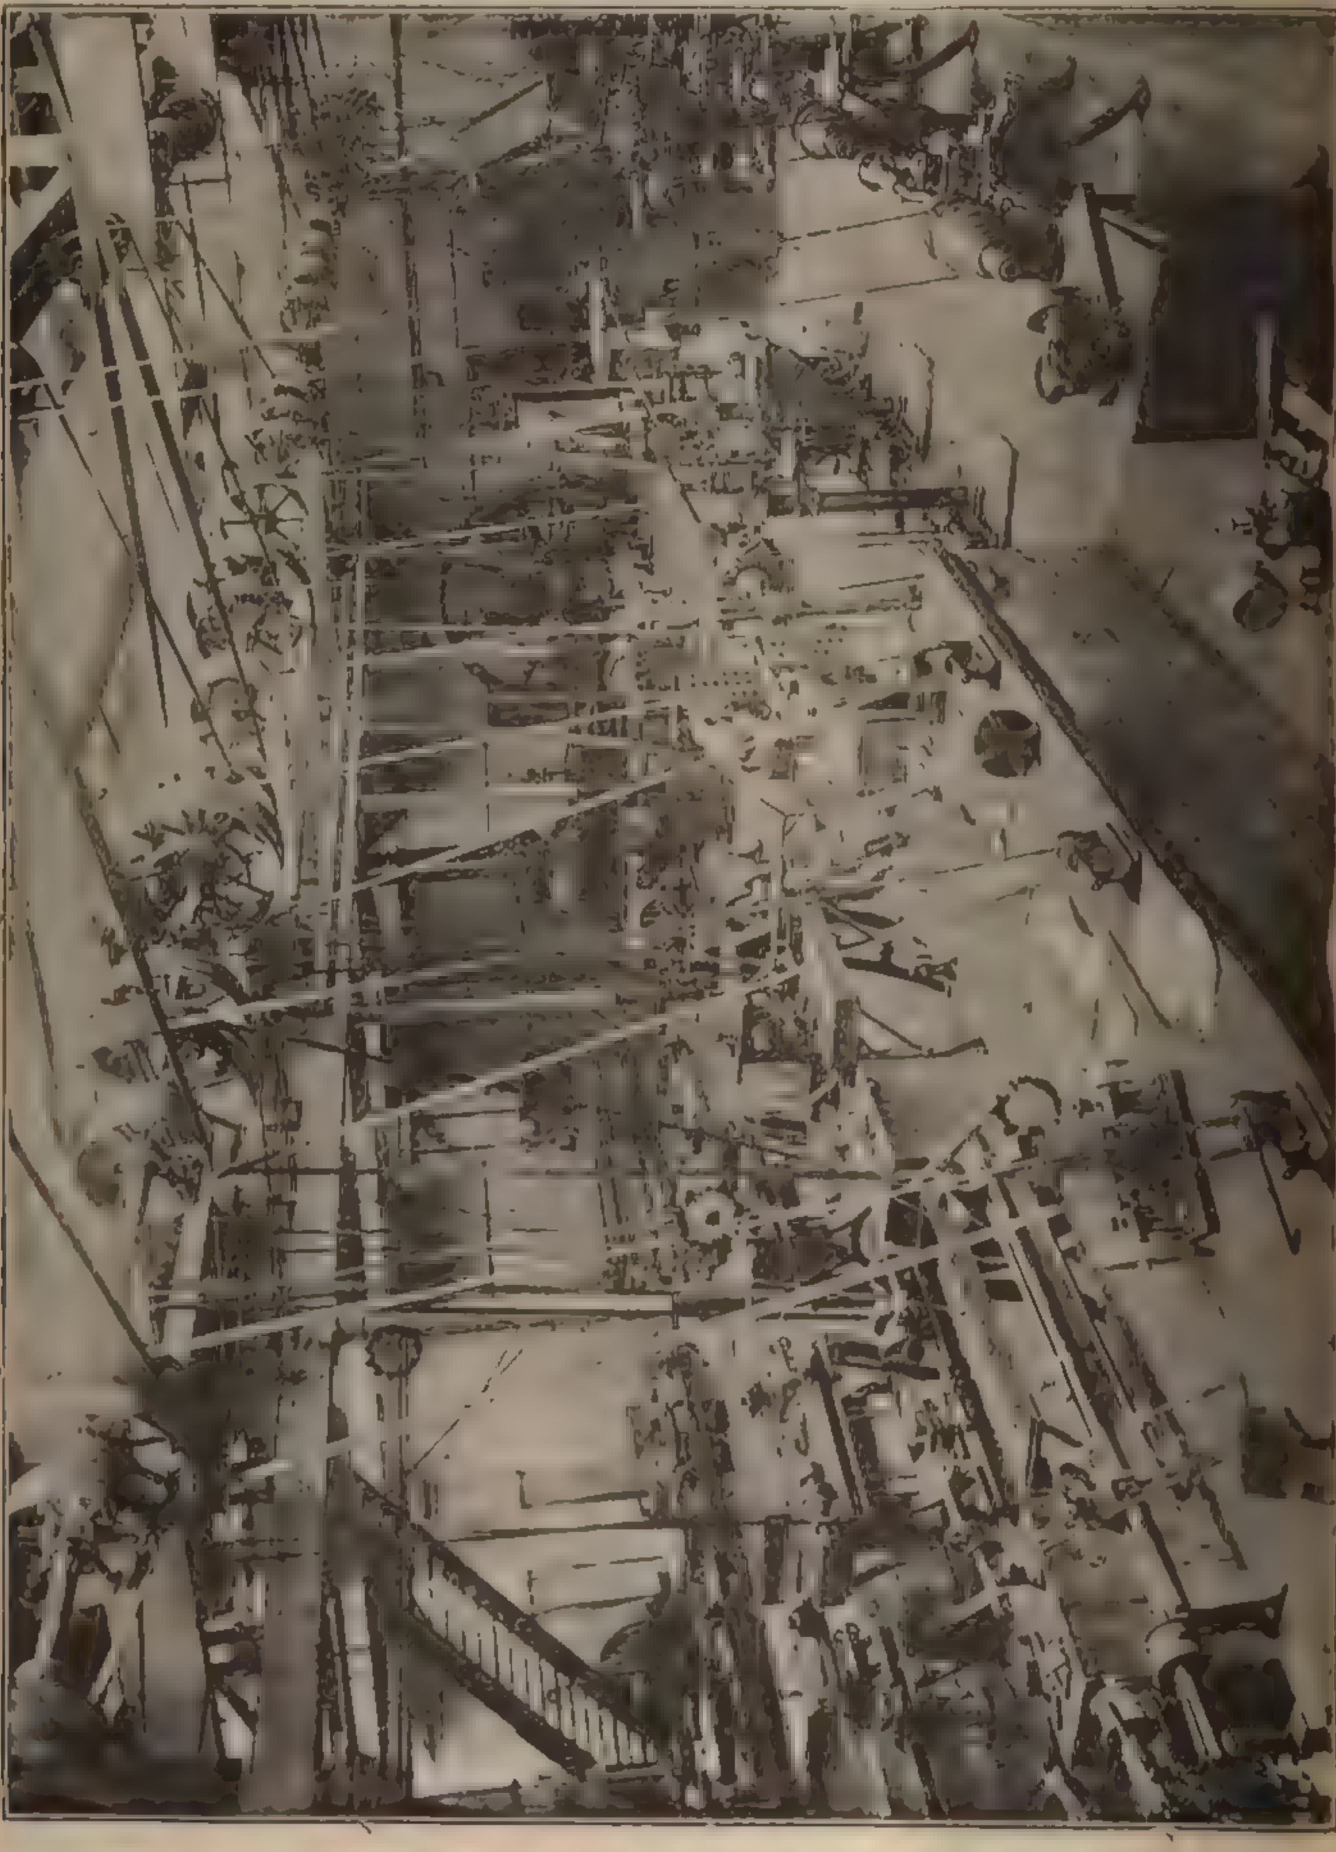
The Goodwin Sands.—There is, says the *Western Morning News*, some prospect of an early establishment of telegraphic communication between the lightships placed on the Goodwin Sands and the shore. Although it is understood that the Trinity masters have yet to report the result of their recent investigations, it was semi-officially stated in a letter received by the Dover Town Council from a gentleman who has for a long time interested himself in this matter, that it had been decided to connect the East Goodwin lightship with Dover and the North Sands Head lightship with Ramsgate. The Trinity masters visited the Goodwin lightships a week or two ago, and took soundings in connection with the proposed scheme. The North Sands Head lightship is about eight or nine miles from Ramsgate, being directly opposite Broadstairs. It is also about equi-distant from Deal as compared with

Ramsgate. The East Goodwin lightship is directly opposite Deal, about seven miles from the shore, whilst the southern extremity of the sands is marked by the South Sands Head lightship, about six miles from Dover, and nearly opposite the South Foreland lights. It is not yet known how the proposed scheme will be carried out, but it is thought that a connecting cable will run between all the lightships, terminating at Ramsgate and Dover. The sands have four lightships, the fourth being the Gull light, in the Gull stream between the sands and what is known as the Brake Sand—running between Ramsgate and Deal. The effect of circuit communication of this character would be that lightships could telegraph for assistance from whichever point wind and sea would permit it to be obtained, as it often happens that, although a vessel in distress is nearer to Ramsgate than to Dover, the direction of the gale would enable the tug and lifeboat to proceed much more easily and quickly from the latter port. Probably there are no "sea-traps" in the world which have so gruesome a record of wrecks as the Goodwins. At low water, although seven or eight miles from the shore, the sands are high and dry, the banks in some places being so sharp in their declivities that vessels run from deep water directly on to the sands. At high water the sea is always disturbed, and in rough weather the roar of the breakers can be heard for a considerable distance. There have been schemes under consideration for coping with the dangers of the Goodwins, but very few of them have been at all practical. One scheme was for the construction of a lighthouse with a sailors' chapel annexed resting on wooden piles in the sands; another was for the making of a harbour of refuge in the sands by encircling what is now known as Trinity Bay, the harbour to be named after the Prince of Wales. This was proposed in 1843, and embraced an elaborate scheme of docks, warehouses, and fortifications. The author of the scheme was Mr. Bush, C.E., and it was estimated to cost a quarter of a million, but it did not meet with any support. The scheme of connecting the lightships with the shore telegraphically is, however, eminently practical, and is probably the only way to reduce the dreadful death-roll of the sands. It will not only ensure speedy communication with the shore, but it will enable directions and instructions to be given of the greatest value to those on shore in going off to rescue a crew. The greatest difficulties to be contended with at present are fogs and snowstorms, during the prevalence of which it is impossible to give signals to the shore, or for a lifeboat to find a ship. It frequently happens that a vessel gets on to the sands in the night during a heavy gale, and is a wreck before any communication can be obtained with the shore, and the same thing happens in snowstorms and fogs. At the present time the masts of the "Hazlebank," a new iron ship on her first voyage, which struck during a fog on the south end of the bank, can on a clear day be seen from Deal above the water.

Catalogue of Central Stations.—It certainly must be a satisfaction to the authorities of a municipality to be able to know a firm to whom they can telegraph "Please supply a central station for 100,000 lamps, plant for 5,000 to start within a fortnight," or words to that effect, as the lawyers say. The catalogue of Messrs. J. E. H. Gordon and Co., Limited, of 11, Pall-mall, takes the standpoint, that the demand for complete central stations is becoming extensive; that they are contractors for central stations, the only large contractors not tied down to any particular system; that they have carried out as engineers or contractors a number of the most important central stations of Great Britain; and that as they are frequently asked for their catalogue the best answer would be drawings and descriptions of the principal works carried out under their superintendence as engineers or by their contractors, with the approximate cost of each. Where the cost of items apiece is some £60,000 or £100,000 this is evidently not easy to do within exact limits, as town requirements differ, but Messrs. Gordon will on receipt of plan of town and particulars, forward within a few days an inclusive price for a station with plant and mains ready for work. The case most likely to occur is when a municipality or company is anxious to start a station and expect that when started it will be largely supported, but at the same time they only wish to spend a small amount to begin with. Special attention is given to this point, and tenders will be given for a complete scheme, together with plan for establishing at first a small portion complete in itself, yet so that the small plant will not need alteration or replacement, but will form an integral part of the whole scheme. The success that has attended the installations already carried out by Messrs. Gordon in England and Ireland are sufficient to demonstrate that the firm are thoroughly reliable and competent to fulfil their promises with complete satisfaction, and the issue of this interesting catalogue of central stations will serve to spread their renown as electrical engineers. The first description, with full-page illustration, is of the old Paddington, G.W.R., central station of 1,900 h.p., which has been at work since 1886, erected under the superintendence of Mr. Gordon. The Manchester-square station of the Metropolitan Company, erected by the Electric Construction Company, to the designs of Mr. Gordon, forms a more modern example of an alternating-current distribution. It has 50,000 lights capacity, and is one of the best-arranged stations in London. Another station of the Metropolitan Electric Company, Rathbone-place, was also rearranged completely to Mr. Gordon's designs. Since the firm became Messrs. J. E. H. Gordon and Co., Limited, several electric light stations have been carried out entirely by them as contractors. Carlow is a well-known example, and is of special interest, as water power is successfully used and transmitted electrically from Milford, five miles away. The Town Commissioners express themselves "highly pleased" with the public lighting. The streets are lighted by 12 arc lamps of 1,200 c.p. and 40 incandescents of 16 c.p., and the plant is capable of supplying, in addition, 1,300 lamps of 8 c.p. to private consumers. The total cost was about £10,000. The total revenue of the Carlow Gas Company is about £1,700, and of this nearly £400 was secured by the electric company in the first six months. An interesting photograph of the Carlow streets is given, and also the station itself, inside and out. At Larne the central station cost £12,000. The town is lighted by 11 Brockie-Pell arcs and 50 incandescents, the system being alternating-current with steam plant. The Town Commissioners are "highly satisfied." Photographs of the plant at this station are shown. Bray, the Dublin Brighton, was lighted for £20,000, the dynamo being driven by water power. There are 117 public lamps—23 arcs and the rest incandescent; and private lighting is also given. The illustration of the Bray station shows clearly the arrangement adopted. The last central station shown is that at Sydenham, which we have fully illustrated in our columns. The contract was for 20,000 light plant for £51,175, and it was completed and the light running in 67 days, 2½ hours before the Press view of the Crystal Palace Exhibition on January 8. Some magnificent reproductions of photographs of the Sydenham plant are given with detail drawings, and it can be seen that this "catalogue of stations" supplies collected information of the greatest interest to public authorities at the present moment.

RONALD A. SCOTT'S WORKS.

We must confess to a good deal of satisfaction during a recent visit to Ronald A. Scott's works at Acton Hill. For



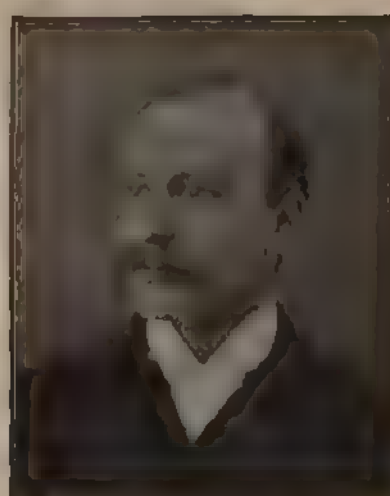
many years past we have been strenuous advocates of factory experience rather than laboratory experience for those who intend making electrical engineering a profession. A combination of the two, however, would be desirable. The mere laboratory student is a somewhat useless animal during the earlier days of his entering into the rough, practical life of an engineer, while the factory worker has his peculiar idiosyncrasies which are not always pleasant. The latter, however, if he has any go in him at all, makes the better man. He is familiar enough with

STEPNEY RAWSON.

PROF. JOHN PERRY.

DESMOND G. FITZGERALD.

JOHN B. VERITY.



W. M. MORDEY.

Among the most recent developments of electrical apparatus by this firm is one in connection with military operations at night, described in our issue of September 16.

Fig. 5.—Positive.

Fig. 6 – Negative.

Still more recent is the perfection of "writing on the clouds." It is well known that for some time efforts have been made by various enterprising people to adapt electric search-light apparatus to advertising purposes. Mr. Ronald Scott has not only attempted the clear throwing of words to a distance, but has succeeded in doing it.

Fig. 4. Hand Lamp.

Some weeks ago we were cognisant of his work in this direction, and have been kept informed of the progress of the experiments which we witnessed on Tuesday night last. For some time before we reached Acton Hill Works we could see the beam of light being turned in various directions. We could also see that the light was distinctly separated into parts, but the night was clear, cold, and starry, with no clouds upon which to throw the beam. So it was not till we got nearer the point of experiment, and could see the beam of light thrown on to distant trees, that we could distinguish the letters. These were clear and well defined, and, of course, proved to be the inevitable "Pears Soap" met with everywhere. The search-light was turned in all directions, and wherever there was a material object upon which the beams could impinge, the words were distinctly seen. Altogether, the experiment was most successful, and, as always is the case, the result, as we were informed, is obtained in a very simple manner; but as the arrangement forms the subject-matter of patents we were prevented from seeing or saying more. Altogether, then, we look upon these works as producing good apparatus of the kind to which especial attention is devoted, and as giving practice and experience to those who desire it, and enter its precincts.

THE LEEDS ARC LIGHT SYSTEM.

Judging by the scant display at recent electrical exhibitions, one is led to the conviction that there are still only two or three important types of arc dynamos for series lighting, and that these have experienced little, if any, improvements during the past few years. In all probability these machines are as perfect as their peculiar design and construction warrants, but it is of the rarest occurrence that results of tests with such dynamos are placed before the public. Of compound wound and shunt-wound dynamos for incandescent lighting or for running arc lights in parallel, there are innumerable types in the market, all claiming the highest possible efficiency. Arc lamps are, as a rule, only used for the lighting of streets, large open spaces, public buildings, and factories possessing lofty rooms. In such cases the distribution of the current to the lamps, if placed "in parallel," involves a capital outlay for copper leads often exceeding in cost the value of the electric generators and lamps combined, even when allowing a very considerable loss of energy in transmission. These facts are well known to electrical engineers, and, wherever possible, "series" arc lighting is resorted to for economic reasons. The following is a short description of a system of series arc lighting evolved by one of the best known engineering firms in the kingdom, Messrs. Greenwood and Batley, of Leeds, who have spared no pains in producing a highly efficient, compact, and economical apparatus. Fig. 1 shows the general arrangement of a 20-light dynamo with the regulating gear attached. By Fig. 2 we can trace the circuit represented in diagrammatic form. The field magnet poles of the dynamo have two small projections, which serve as a magnetic field to a little flat ring armature, M, which is provided with an ordinary commutator and a pair of brushes receiving a weak current through an automatic

reversing switch. This switch consists of an electromagnet energised by the main current, an armature, L, which can make contact with either of the terminals, *a* and *b*, and two resistances, R, consisting of carbon rods about ½in. in diameter and some 6in. long. The slightest variation of the E.M.F. in the main circuit will cause the armature, L, to make contact through *a* or *b*, as the case may be, and send a current through the armature, M, in one direction

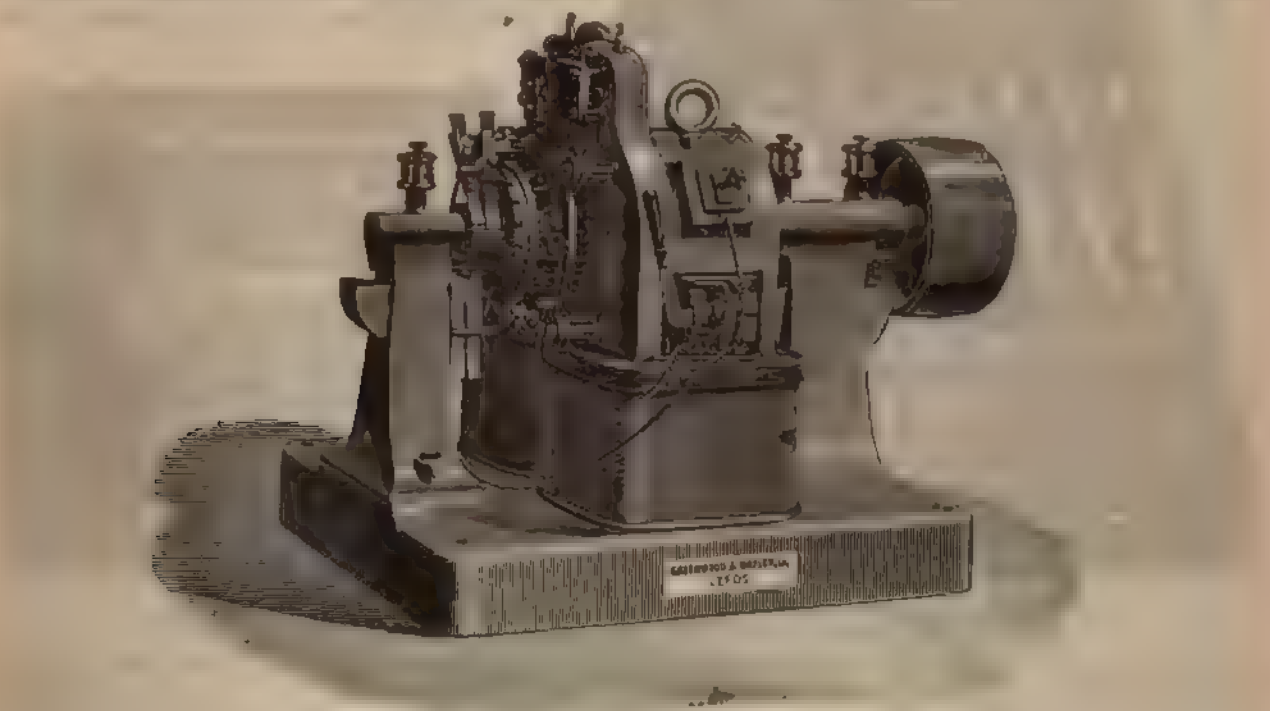


Fig. 1.

or the other, and thus cause the latter to revolve forwards or backwards. By virtue of this rotation of M, the circular rack, S, supporting the brushholders of the dynamo will move slowly (it being driven through a small train of wheels geared to the spindle of M), and thus adjust the position of the dynamo brushes to suit the E.M.F. demanded by any number of arc lamps arranged in series. Contrary to the expectations of some electrical experts, there is no

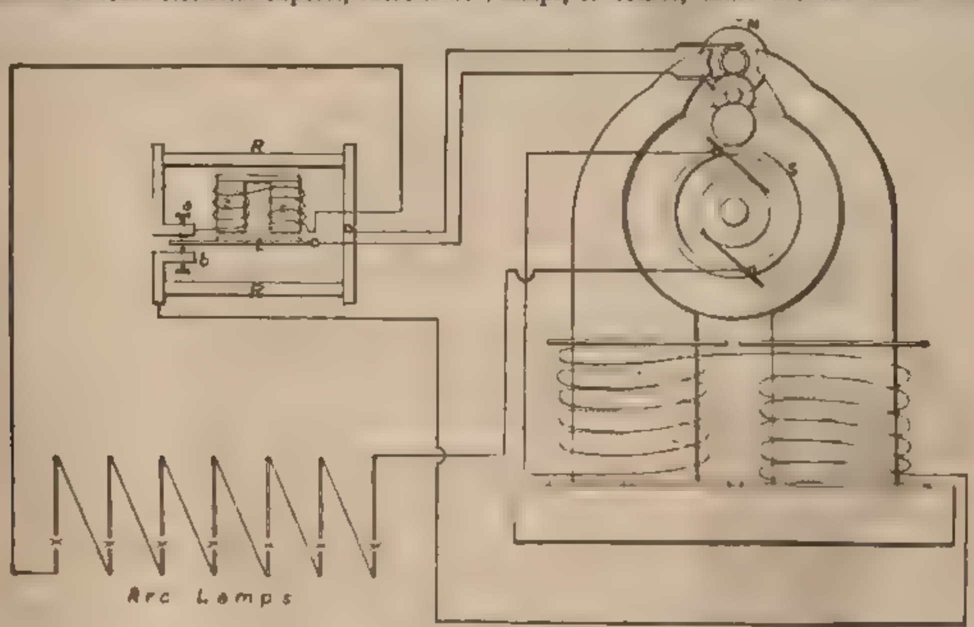

Fig. 2.

"hunting" in the regulating gear—the energy used in actuating it is exceedingly small, and the efficiency of the whole machine at various loads remarkably high. The following tests made on a 20 light machine will show this most clearly. The machine was driven by an electric motor, the brake horse power of which was easily ascertained, running at a constant speed of 750 revolutions per minute. The current was constantly at 10 amperes, and the average voltage measured 47 volts per lamp.

Test of the Leeds Arc Dynamos.

Number of lamps. 2,000 n.c.p.	Speed Revolutions per minute.	Current. Amperes.	Brake h.p. absorbed.
5	750	10	6·31
6	750	10	6·96
8	750	10	7·81
12	750	10	10·65
16	750	10	13·1
20	750	10	15·2

The regulator absorbs only 21 watts, or about ¼ per cent. of the maximum load—quite a negligible quantity. There is no sparking at the contact-maker, and when once adjusted the automatic regulator will act promptly and without any further attention, except an occasional dusting. By the Leeds arc light system it is possible to run incandescent lamps in series with arc lamps. Such incandescent lamps, of course, must use the same current as the arc lamps, and they are fitted with holders and switches, to be put in and out at will. The economy, simplicity, and utility of having both arc and incandescent lamps run in series from the same dynamo will be appreciated, especially in such cases as the lighting of mills, factories, and public halls, where the greater part of the lighting is done by means of arc lamps, but where a few incandescent lamps would be useful in offices and rooms forming part of the premises.

* This order authorised the transfer to the Edison and Swan United Electric Light Co., Ld., of the powers, etc., granted by the following orders—viz., St. James's and St. Martin's (London) Electric Lighting Order, 1883; Hanover-square District (London) Electric Lighting Order, 1883; South Kensington Electric Lighting Order, 1883; Strand District (London) Electric Lighting Order, 1883; Victoria District (London) Electric Lighting Order, 1883. These orders have since been revoked.

† The Liverpool Electric Lighting Order, 1892, scheduled to the Electric Lighting Orders Confirmation (No. 4) Bill, now before Parliament, contains a provision for the repeal of this order.

(To be continued.)

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 10d.	9s. 11d.	19s. 10d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With this issue of the Paper is given a Supplement containing Portraits, taken from photographs, of **Prof. John Perry, Mr. Desmond G. FitzGerald, Mr. Stepney Rawson, Mr. J. B. Verity,** and **Mr. W. M. Mordey.**

Every reader should see that he gets this Supplement, and non-delivery with the Paper should be reported at the Publishing Office.

THE "BELFAST EVENING TELEGRAPH."

It is not often that we have to mete out unstinted praise towards our political contemporaries. Too often they do much harm to an industry they do not understand, and fill their readers with a kind of information that is more than misleading, being absolutely contrary to truth. The great London dailies seem to take every opportunity of giving tongue and credence to the most astonishing rumours from the Continent or America. It is, therefore, a pleasing surprise to find the *Belfast Evening Telegraph* sending a special commissioner to London in order to examine and report upon the electric lighting as represented in the metropolis. The special commissioner has contributed at least eight long articles to his paper, and, with one peculiar exception, has gathered together information that should at least assist in educating the citizens of Belfast in matters electrical. Of course these articles can hardly be classed as technical. They contain erudite and recondite allusions to men and manners outside the pale of the electrical industry, and the commissioner seems to have been satisfied with discussing three or four typical installations. By far the greatest space and attention is given to the work of the Brush Company, not only in connection with its work at Bankside for the public lighting of the City, but also in regard to its general and, if we may say so, its historical work and future policy. The last information seems a little out of place, though in a measure it is advantageous to refer to it. Let us explain. In article No. 4 we have the following: "In common with all other compaies here, the Brush Company labour under a disadvantage in not being able to manufacture the glow lamp, but they are eagerly looking forward to the happy time—I believe November next year—when the Edison patent will lapse, and when there will be no restriction upon the progress of domestic lighting." Now we hardly take the remarks made in these eight articles as the spontaneous utterances of the commissioner. He has naturally been flooded with information and with the opinions of his hosts, and has, to a greater or lesser extent, reproduced the opinions given in his hearing.

Is it not, then, a mistaken policy for the Brush or any other company to rail against the working of the patent law? They are earnest enough in claiming all their rights in connection with their own patents and in proceeding against infringers, and cannot for a moment contend that they have not endeavoured to make as much profit as possible out of the patents they control. Why, then, should Edison, or Swan, or Sawyer be more or less held up to opprobrium because they are the holders of certain patents which give them the monopoly of manufacturing incandescent lamps? Surely the Brush Company would not wish to see the patent laws abrogated. They, through the commissioner of the *Belfast Evening Telegraph*, seem to hint that patents are wrong, and whenever or wherever anything is discovered and patented it is a mistake to give the discoverer a monopoly, and to disallow for fourteen years any man or firm making the articles so dis-

covered. It may be, however, that our interpretation of these remarks is incorrect, and that all that was meant was to indicate that ere long the cost of the lamp would probably be lessened, and to hold this out as an inducement to carry out an electric lighting project in Belfast. The cost of renewals of lamps, as well as initial cost, is indeed an item to be considered, but it is not of sufficient gravity to be made rank as a disadvantage to the Brush and every other company. The inability to make lamps is no more a disadvantage to the Brush Company than the inability to make Mordey alternators is a disadvantage to Brown, Jones, and Robinson. Let us put in an aside; like our contributor, Mr. Ansell, we intensely dislike the term glow lamp, and prefer to use incandescent, but the commissioner has been primed with "glow," and glow to him it must be. Descriptions are given of the lighting of clubland, of the St. James's installation and district, of the gigantic Deptford installation, and of St. Pancras. The commissioner falls into some error in his description of the Deptford installation. He assumes or has been told that Ferranti's gigantic machines are running, but that is not so. Otherwise, as we have said, the information given is fairly accurate, and such as should give the readers of the said paper a fair idea of what is being done in London.

CORRESPONDENCE.

"One man's word is no man's word.
Justice needs that both be heard."

TRANSFORMER DESIGN.

SIR,—In your issue of the 7th inst. is an article by M. F. Géraldy, entitled "Transformers made by the Société l'Eclairage Electrique." In this article M. Géraldy appears to be under the impression that the rule of thumb is still the principal factor in the design of alternate-current machinery, and cites as an instance the Lauffen-Frankfort experiments, where the generating machine designed for 300 h.p. is represented as only giving 120 h.p.

M. Geraldy appears not to have read the results of the tests made by the committee of the Frankfort Exhibition, in which the machine was loaded to 200 h.p., when it gave a commercial efficiency of 93·5 per cent. It was impossible during the exhibition to test the machine on full load owing to the absence of a suitable resistance at Frankfort. As a matter of fact, the same machine is now supplying current for the lighting of the town of Heilbronn, situated about six miles from Lauffen, and its output during the period of greatest demand attains 300 e.h.p.

For my part, I consider that many of the theorists do not sufficiently understand the conditions involved in the actual design of alternate-current machinery to render them competent critics.—Yours, etc.,

C. E. L. BROWN

OUR PORTRAITS.

FitzGerald, Desmond Gerald Manners, to give his baptismal name in full, was born in February, 1834, at Parliament-place, Westminster. His father, Edward Marlborough FitzGerald, at one time private secretary to his cousin, Lord FitzGerald and Vesey, president of the Board of Control, was well-known in literary circles. His mother (Charlotte Julia), who still survives, is the elder daughter of the late Sir Richard Mounteney Jephson, judge-advocate at Gibraltar, whose younger daughter is the present Dowager Marchioness of Ailsa. Sir Richard's surviving son, the present baronet, is General Sir Stanhope Jephson, C.B., who served with distinction in India under his uncle, Lord Keane, commander-in-chief. Thus, the subject of our present notice, a godson of John Forster, and brother-in-law of the late General the Right Honourable Sir Thomas Montagu Steele—who for some years commanded her Majesty's forces in Ireland—belongs to a literary and military family; none of whom, it may be said, had any sympathy with his taste for science in general and electrical applications in particular. Mr. FitzGerald's personal reminiscences of the literary celebrities who visited at his father's pretty house, Elmstead, near Bromley, might be very interesting in a literary journal, but would be out of place here. At the age of 13 he was placed at a school in Vincennes connected with the University of France. The events in Paris of 1848 produced a strong and lasting impression upon his mind. Returning to England at the close of 1850, he spent some years in making acquaintance with English society, and in fits of somewhat desultory study. The lectures on chemistry of Robert Hunt, at the School of Mines, first turned his attention to this science. The *res angusta domi* at length led to his accepting an appointment in the Colonial Land and Emigration Office, under the late Sir Stephen Walcott. Here, with his continental notions of behaviour and etiquette, he found himself entirely out of place, and in about a year accepted the position of assistant secretary to the Submarine and European Electric Telegraph Company, then located at 30, Cornhill. Here he made the acquaintance of Mr. France, the engineer to the company, and also of Mr. Bakewell, the inventor of the copying telegraph, and of that extraordinary genius, Alexander Bain, who was employed "as a workman" by Sir Charles Wheatstone. At the instance of his friends he left the Submarine Company to take up an appointment at the Legacy Duty Office, Inland Revenue, where he held her Majesty's commission. In three years' time, however, disgusted with the behaviour of the then Comptroller of Legacy Duties, he resigned his appointment, and maintained himself for some years by literary work. At this time he made the acquaintance of Mr. Healey, of the *Engineer*, and commenced to write for that paper, which still, we believe, considers Mr. FitzGerald as a member of the staff. He also established a laboratory, and commenced in earnest the experimental study of electricity, as well as of chemistry. In this pursuit he received no encouragement; but his friends obtained for him, and induced him to accept, an appointment in the Store Branch of the War Office, Pall-mall. Here he remained during the period of Sydney Herbert's tenure of office, and for some portion of that of Major-General Peel. But his mind was too earnestly devoted to scientific studies to allow of his giving his time to the routine duties of official work. About the end of 1861 he resigned this appointment in order to start the *Electrician* (old series), which may be said to be the first paper exclusively devoted to electricity. This paper was continued under many difficulties and discouragements, until May, 1864; after that period, he wrote frequent articles for several of the technical papers, and was for some time editor of the *Electric Telegraph Review*. Mr. FitzGerald was lecturer and examiner at the School of Telegraphy and Electrical Engineering from its commencement until it passed into the hands of the late Dr. Lant Carpenter. Many of the foremost among the rising generation of electricians received their first technical instruction from his lectures. As most of our readers are aware, Mr. FitzGerald is still working energetically on various practical problems of electro-chemistry—*e.g.*, secondary batteries, standards of E.M.F., and electrolytic production of "bleach" and alkali.

Perry, Prof., John, M.E. (Master of Engineering), **D.Sc., F.R.S., Assoc.M.I.C.E.** Born at Garvagh, a town in Ulster, in 1850. His earlier education was obtained at the Model School in Belfast. An account of his life from that time to this is almost or quite a description of constant successes in everything that he has touched. He gained prizes at school, on matriculation, and in college. He gained Whitworth Exhibitions in 1868 and 1869, and a Whitworth Scholarship in 1870. This was after serving an apprenticeship to the firm of Messrs. Coates, of the Lagan and Prince's Dock Foundries, Belfast. His

career after leaving tended educationally, and he went to Clifton College as lecturer in physics. During his stay there he published an excellent "Elementary Treatise on Steam." Leaving Clifton, he became Thomson Scholar and hon. assistant to Sir Wm Thomson in Glasgow, during which time he was constantly employed in literary work. In 1875 he went to Japan as joint professor of engineering, and returned to England in 1879 Some of our readers may recollect that so energetic was Prof. Perry, with his other professional colleague in Japan—Prof. Ayrton—that at one time it seemed as if the hub of the scientific universe had migrated from England to Japan. The scientific papers of these colleagues are very voluminous. On returning to England, he at first associated himself with Messrs. Clark and Muirhead, but the leaning towards the literary and educational proved too strong, and, in 1882, he became professor of mechanical engineering at the Finsbury Technical College. Since then, Prof. Perry has added to his reputation as an admirable lecturer and as a sound scientist. In June, 1885, Dr. Perry was elected a fellow of the Royal Society. If his energy continues to be as active in the future as it has been in the past, we should be afraid to say how many columns of the Royal Society's catalogue this indefatigable writer and investigator will at length appropriate under his own name.

Mordey, Wm. M , M I.C E., was born in 1856, and at the early age of 14 entered the Postal Telegraph service, in which, after serving a short time in London, he was removed to Bradford, in Yorkshire. Like most other men who have made their mark in the sands of our time, Mr. Mordey, while pursuing his ordinary avocations, was anxious to perfect himself in the theory of the subjects in which he was practically engaged, and devoted a considerable time to study. That his knowledge in this direction was successful is seen by the fact that he was asked to organise and conduct classes for the study of electricity and magnetism, in which he was very successful. In 1881 he left the telegraph service for electrical engineering in the broadest sense, and went as electrician to the Brush Company, with which company he has remained ever since, and from the first his talents asserted themselves. He commenced with the Brush Company as superintendent of the testing department, but was ere long advanced to be the electrician of the company. As most of our readers know, Mr. Mordey's papers, which have been contributed to various societies, have been of the greatest practical character. He devoted his attention to the perfecting of the machines as constructed by the Brush Company with great success, till his name has become a household word amongst those who are engaged in constructing dynamos. For a paper by him on "Some Prejudicial Actions in Dynamo Machines," read in 1884, he received the honourable mention of the Council of the Society of Telegraph Engineers In the same year he described, before the Institution of Civil Engineers, the methods and constructions that are best adapted for working compound dynamos of similar, as well as unlike, size, powers, or speed, in parallel circuit. To the *Philosophical Magazine* for January, 1886, he contributed an article on "The Dynamo as a Generator and as a Motor · Some Analogies and Contrasts,' in which some experiments and observations, made by himself and Mr. C. Watson, were described that threw something more than doubt upon many of the views that had generally been held with regard to electric motors. The conclusions arrived at in this article have passed into general practice, although at the time they were diametrically opposed to the teaching of well known authorities on the subject. At the British Association meeting of 1886 he read a paper and showed some experiments on "An Electric Motor Phenomenon," illustrating very forcibly some effects of self-induction. In the same year, before the South Wales Institute of Engineers, he read a paper dealing with the subject of the possibility of explosions in fiery mines with incandescent electric lamps. In 1887 he was engaged at the Victoria Works of the Brush Company on his "alternator," an alternating current dynamo of a new type, which, together with his transformer and other apparatus, have been successfully introduced by the company under the title of the Mordey-Victoria alternate-current system. This system is now being used for general lighting in about 50 towns abroad and at home. Amongst other important places, it is now being installed for the lighting of the central and western districts of the City of London. Mr. Mordey was in 1888 elected as associate member of Council, and in 1890 a member of Council of the Institution of Electrical Engineers, before which Institution in 1889 he read an important paper on "Alternate-Current Working," dealing with many branches of the subject, and especially with the principles underlying the best construction of alternators for the purpose of parallel working and for synchronising motors. For this paper he received the Institution premium of the year. In 1891 he visited the United States, mainly to examine the systems of electric traction in use in that country. He is a member of the Physical Society and of the American Institute of Electrical Engineers. He is on the Electricity Committee of the Royal Commission for the Chicago Exhibition of 1893.

Rawson, Stepney, M A. Born 1854, educated at Westminster School (where he was captain 1873), and Christ Church, Oxford, where he took honours in the mathematical schools—B.A. 1877, M.A. 1880. After leaving Oxford, Mr. Rawson devoted himself for five years to scholastic work, but being compelled by ill health to relinquish this, he joined the firm of Woodhouse and Rawson in 1882 He was associated with the development of the firm's incandescent lamp business, and in connection with it he applied himself to the question of standards of light, which resulted in the firm undertaking the manufacture of Mr A. V. Harcourt's Pentane Standard lamps. He also, at this period, was employed in the investigation of the Welsbach incandescent gas lamp, and was the originator and patentee of the method by which the fragile incandescent bodies were rendered portable, thus overcoming the principal difficulty connected with the system. Since 1887 Mr Rawson has been engaged by Woodhouse and Rawson as technical expert to report upon the various processes brought under their notice. He was, in his earlier days, well known as an athlete, and is now an ardent lacrosse player. He has been heard more than once at the concerts of the Electro-Harmonic Society He is a member of the Institution of Electrical Engineers, and other scientific societies.

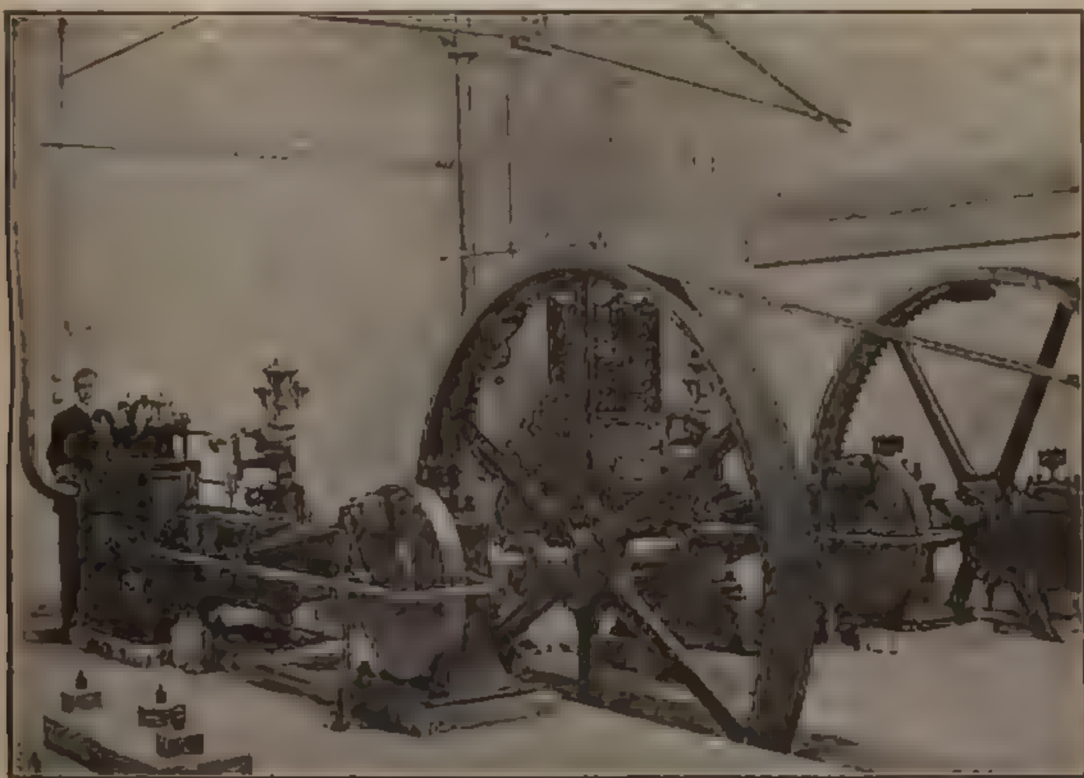
Verity, John B, born in 1864, as is well known, is one of the firm of Verity and Sons, King street, Covent Garden, whose works are known as the Plume Works, Aston, Birmingham. Mr. Verity, although young, has won his spurs in the business world, and if the foresight and energy he has put into the development of the electrical part of his business continues, the firm will take a still higher rank in the industrial world. So much are the business instincts of Mr. Verity valued that he is a director of the Metropolitan Company, the Electric Construction Corporation, the Nassau Steam Press, the British Chemical Company, and senior of Messrs. B. Verity and Sons But Mr Verity has other obligations besides those of business, and is an active politician, being the president of the Aston Liberal Association. He is also an income-tax commissioner, so that his life may safely be said to be a busy and a useful one. Some years ago Mr Verity travelled over a great part of South Africa, but latterly his avocations have left him less leisure, and his trips are restricted to the States. He is the author of a popular book on electricity.

ABERDEEN ROYAL INFIRMARY.

This installation has been made and erected to the specification and under the supervision of Prof Jamieson. It consists of two safety Babcock and Wilcox multitubular boilers, of 100 h p. each, working at a normal pressure of 120lb. per square inch. The boilers are fed with feed water by Messrs. J H Carruthers and Co's duplex pumps either direct or through a special feed water heater (supplied by the boilermakers), and a complete range of Messrs Green and Sons' fuel economisers. This provides that the feed-water shall be raised in temperature considerably above ordinary boiling point before it enters the

boilers, thus ensuring economy and freedom from stresses in the tubes. The feed-water as it passes through the heater is heated by the exhaust steam from the engines, and on its passage through the Green's economiser by the waste gases from the furnaces as they pass from the boilers to the chimney. The steam for use within the infirmary buildings proper is reduced in pressure by means of Auld's patent reducing valves, so as to prevent danger, but that for the electric light engines is conveyed direct to them at full pressure by specially strong cast-iron and copper pipes made by the boilermakers, and by Messrs. Abernethy and Co., of Ferryhill. All steam and hot-water pipes within the boiler and engine rooms have been thoroughly lagged by Messrs. Wormald and Co.'s fibrous non-conducting material, in order to prevent condensation, and thus tend to the saving of fuel.

Engines and Dynamos.—For the purpose of driving the two Castle dynamos, there have been fixed on very solid foundations, prepared by Mr. Kelly, the architect, two horizontal engines by Messrs. Marshall and Sons. These engines are fitted with Dr. Proel's patent automatic cut off gear, controlled by a sensitive governor, whereby steam is



Engine Room at Aberdeen Royal Infirmary.

admitted in proportion to the load, and their speed kept practically constant at 96 revolutions per minute. Broad orange tan belts, by Messrs. Tullis and Co., of Glasgow, connect the flywheels of each engine with its corresponding dynamo. The belts may be eased or tightened at pleasure, either whilst the machinery is standing, or in motion, by horizontal screws, which push or pull the dynamos on their foundation rails towards or away from the engines The dynamos, as well as the whole of the electrical plant and fittings, have been made or supplied and fitted up by Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne, who also had the contract for the engines and storage cells. The dynamos are of the high-resistance shunt type. They are so coupled up that they can be used either for lighting the incandescent lamps direct, or for charging the storage cells, or for working in conjunction therewith as occasion may require. When used for direct lighting, they deliver the electrical energy at a constant pressure of 100 volts when running at 720 revolutions per minute, but when charging the accumulators, the pressure is generally 135 volts, to overcome the back E.M.F. of the cells. Each engine and dynamo is capable of supplying 240 amperes, or of lighting the whole of the lamps throughout the building, so that there is in effect not only a complete duplicate plant, but also a reserve of power in the storage cells for use during the very late and early hours, when the engines may be stopped, or in case of anything going wrong with them and the boilers. Foundations have already been laid for a third engine and dynamo, which will light the old buildings now undergoing internal structural alterations.

Switchboards.—The current from the dynamos and the accumulators is conveyed first to a switchboard situated in one corner of the engine room, where the electrical pressure is registered by Lord Kelvin's multicellular voltmeter, and the quantity of current by J. H. Holmes's patent ammeters. It is there distributed by means of Castle quick break switches, and sent through safety fuses to the subsidiary switchboard fixed opposite the day and night porter's room, where it can be turned on to or off from the different sections of the building as required.

Leading Wires and Lamps.—Throughout the whole of the surgical block, laundry, etc., there have been fitted up, in specially prepared canary wood grooved casings, several miles of highly insulated cables and leading wires These cables and leads convey the current from the subsidiary switchboard to the various lamps of which there are over 400 ranging from 8 c.p. to 150 c.p. each, according to their position and use. For example, eight-candle lamps have been fitted into small closets, and the portable lamps for bedsteads, etc.; 16-c.p. lamps for ordinary lighting throughout the building and 150 c.p. lamps for the operating-theatres, also engine and boiler rooms. Each bed is not only fitted with a reading and a portable light for examining patients, but also with wall attachments, so that the special electro-medical appliances (so useful in certain treatments of disease) may be affixed thereto, and manipulated with ease as well as freedom from danger. In the oculist department a dark room has been provided, with a universal motion bracket, and reflectors for concentrating or for reflecting parallel rays.

Accumulators.—In such an installation as this at the Royal Infirmary, the arrangements would not be complete without storage cells, whereby current may be obtained of any desired pressure at any time during the day or night, either for lighting or for medical use. The last pattern of the Electric Power and Storage Company's cells (or K type) are installed. They are situated in a compartment by them-

selves at the end of the dynamo-room. This compartment has been specially ventilated so as to carry off the gases generated during charging.

Electrical Plant Buildings.—The architect (Mr. Kelly) has carried out in a most substantial manner the general requirements for space and arrangement of plant demanded by the consulting engineer.

During the progress of the works Mr. Norman Whitelaw, a former student of the Glasgow and West of Scotland Technical College, has acted as electrical and mechanical inspector under Prof. Jamieson.

The engine and boiler rooms, together with all machinery, etc., cost over £8,000.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE III.

(Continued from page 359.)

The machines which are at our disposal with alternating currents are enormously varied in character. First, let me speak a few words about the ordinary continuous-current motor with a commutator. When we use alternating currents with them, of course it is essential to have the field magnets laminated, or made of sheets of thin iron, in order to prevent the waste due to the formation of eddy currents—Foucault currents, as they are called—in the iron of the field magnets. Even then the machine will not work with the alternating currents of high frequency; but I stated in my last lecture that it is practically certain that when we come to the future of alternating current distribution we shall be dealing with very much lower frequencies than we have been dealing with in the past. With low frequencies such continuous-current motors will work extremely well. As I said in my last lecture, referring to this question, an ordinary 10 h.p. continuous-current motor with laminated fields, made for 100 volts, would, owing to the self induction of the circuit, have its output reduced about 50 per cent., because 100 volts being required for working the armature, another 100 volts would be required for getting over this self induction; whereas, if we reduce the frequency of alternation down to the frequency which occurs in the armatures of ordinary continuous-current machines, we should only be using six volts out of 100 for this purpose; so that we might say that it is within the range of practical working. Simply for distribution in a town, if the question were asked at this present moment, it is quite possible that it is this type of motor which it would be most desirable to use. The reason is that this motor, arranged for alternating currents by having its field magnets laminated, is able to do exactly the same work as the continuous-current motor is at the present time, that is to say, it is able to be stopped and started as frequently as you please with the utmost convenience, and, moreover, it has the enormous advantage of producing greater force tending to turn it at the moment when we start it, than when it is running at its full speed. The very fact of your having a larger current going through it at the start magnetises the field magnets to a greater extent and increases the turning force—the torque—which is moving it. That is a particularly desirable thing in the case of machinery in workshops and so on; but, of course, it is of the greatest importance in the case of our tramcar motors. All tramcar motors at the present time use continuous currents, but, if we were wishing to use alternating currents, it is quite probable that at the present moment this type of motor would be the most suitable and most readily available, and it is more in working tramcars and electric railways that we find the tremendous want of a powerful starting torque—that force at starting, and where the value of the series-wound continuous current motor is so great. That advantage would be reaped also by the same type of motor used with alternating currents.

I have spoken about the possibility of using alternating currents for electric railways and tramways. You might say that there is no advantage in using alternating currents for that purpose; but when we come really to examine the practical cases, such practical cases as are before the engineering world at the present moment, looking at the experience of the South London Electric Railway and looking at the Central London Electric Railway which is being planned for at the present moment, and looking at the half-dozen other lines for which there are Bills in Parliament at this moment, we find that the alternating current possesses a very great advantage over the continuous current. When we are carrying our conductors to great distances, as in the Central London Railway, for instance, a distance of many miles, just as the South London Railway generating station is miles distant from other parts of the line, we find that in continuous-current working at only some 400 or 500 volts we have an enormous loss in our leads, and we have an enormous expenditure of copper in our mains going to these distances. Here our conductors are not buried underground. The expense of laying our conductors is not, as in the case of electric lighting generally, the expense of going underground, and getting round pipes, and getting over other difficulties. Our expense in conductors here is simply in the copper which we put into them. Now, here we have the total gain which the alternating current is able to give us. It is altogether gain here, and if we are able to carry the alternate current by means of high tension over this long distance, and to transform it by means of that most efficient appliance, the alternating-current transformer, down to lower pressures at the place where it is required for working the tramcar or the locomotive, in that case the alternating current will be giving us an enormous advantage over the continuous current. Consequently, it is extremely likely that the alternating current will be adopted in some of these schemes, which are actually before engineers at the present moment, and if such a scheme had to be worked by the alternating current at this very moment, I think that it is extremely probable that we should use alternating currents at very low frequency, alternating some five or ten times per second, using high tension in the mains, and low tension in the secondaries, and using the very continuous-current machines with laminated field magnets that I have been speaking of for the purpose. That is, at the present moment, probably the solution that would be best, but the improvements and advances which are being made in the use of the alternating current with motors are so enormous that I would not say that in a few months the facts may not be different.

I wish now to say a few words about a type of machine which has attracted considerable attention in the past, and which for certain purposes is probably the best that can be used—that is, the synchronising alternating-current motor. This is simply an ordinary alternating-current machine, a dynamo machine for producing alternating currents. It is put upon the circuit and made to work as a motor, and it works as a motor when once you have given it its necessary speed. The motor must be going at the same speed of revolution as the generator of the electricity, otherwise this type of motor will not work.

It has been somewhat of a puzzle to a great many engineers—certainly it has been a great puzzle to the "practical" man that I was speaking of a short time ago—to understand what was the reason that some alternating-current dynamos worked so well as motors and some did not. I think the question has been rendered, perhaps, a little more puzzling by the explanation having been so completely given in certain cases by Dr. Hopkinson. Dr. Hopkinson, some years ago, read a paper before the Institution of Civil Engineers, in which he showed that the self induction which is inherent in the alternating-current machine tends to keep together the two machines when they are acting as generator and motor, and prevents them from getting out of step, and that, therefore, there is a certain amount of power which can be transmitted from the generator to the motor, and the motor can be made to do work. He elaborated this in an extremely interesting paper before the Institution of Electrical Engineers. As soon as these facts were established, a number of the so-called "practical" men immediately set to work to make machines with as much self induction as they possibly could, and they altogether defeated their aims

* Cantor Lectures delivered before the Society of Arts.

The astonishment of many of these men was very great when Mr. Mordey read his most valuable paper—also before the Institution of Electrical Engineers—in which he showed that his dynamo machine, in which there is very little self-induction, and in which there is no iron in the stationary armature, works as a motor most admirably. He gave results which had never been excelled by any alternating-current motor that had been tried, and yet there was very small self-induction in the machine at all. This was rather a puzzler for such men; and, finally, the puzzle was complete when a comparison was made between such a machine as the Siemens alternator, which you all know, and the Mordey alternator. The Siemens and the Ferranti are both the same. The only difference between the Siemens or Ferranti alternator and the Mordey alternator is that, in the one case, the armature revolves, and in the other case the field magnets revolve; otherwise they are practically identical, from an electrical point of view. Yet the Mordey alternator acts most admirably as a motor, and the Siemens or Ferranti machine does not work as a motor. The reason is simply this, that the power which is being given to an alternating motor is of course of a pulsating character, like the current; and there are moments when no power is given to the motor at all. If, then, the motor is doing work, it requires to have a considerable momentum to get over those dead centres, and to be able to continue doing the work, and to get past those dead centres when the generator is giving out no power whatever. Now, the Mordey alternator, in which the field magnets rotate, has an enormous momentum; but the Siemens or Ferranti alternator, where the armature rotates, has very little momentum indeed; and the consequence is that while the Mordey alternator works admirably as a motor, the Siemens or Ferranti alternator does not. All you have to do with the Siemens or Ferranti alternator, to make it work as a motor, is to put a big flywheel to it. There is another method available. Suppose we take two of these alternators, and connect them together on the same shaft, and make them act as a generator for two separate currents going along separate wires; and suppose that for our motor we use two similar alternators, also coupled on a common shaft, each alternator in each pair being electrically separate, so that the one gives or receives its maximum current when the other is giving or receiving its minimum current. One of the generators is feeding one of the motors, and the other generator is feeding the other motor, and the two generators are on one shaft, and the two motors on one shaft. Each of these pairs has got some dead centres. One generator and motor on one circuit have a moment when the motor is at a dead centre; but at that moment the motor of the other pair is not at a dead centre, but is at full work, so that at the moment when one motor, having no momentum, would naturally stop, the other one is driving it on. But it, in its turn, when it comes to a dead centre, is driven on by the first one, which is then in full swing. This is exactly analogous to the method adopted in the ordinary locomotive for getting over the difficulty of dead centres. There we have two cylinders working the driving wheels. One alone would be sure to stop at a dead centre sometimes, and stick and refuse to start the engine; but, by having two cylinders so arranged that the one is giving its maximum thrust at the time the other is giving no thrust, they are always, when they are at rest, in a position to start the engine. That is exactly analogous to the method I have suggested in connection with the Ferranti alternator. That arrangement which I have just now described is really a way of arriving at the rotating-phase motors which have created such interest in the course of the last year. This is not the exact arrangement which has been used generally in the rotating phase motors, but it is one which had been used by some makers and which works successfully. In the great electrical exhibition which was held at Frankfort last year there were a number of motors shown by different constructors, notably some by Mr Schückert, in which a continuous-current dynamo was used, but from the wires of the armature of this continuous-current machine wires were led, not to a commutator, but to rings fixed on the shaft of the motor. Four wires equidistant round the armature were taken to four rings, and from these he was able to take off two alternating currents going along two separate circuits to a distance, to another machine similarly fitted up. Each machine, you understand, possessed a commutator because it was a continuous-current machine; and it also possessed these four rings from which the current could be collected in the form of alternating currents. One of these machines being used as a motor and the other as a generator, we had all the advantages that I have just been speaking of. We had exactly the same effect as if we had had two Ferranti dynamos joined mechanically together on the same shaft and shifted through a distance corresponding to a quarter of a period. These machines worked extremely well. They were able to start, too, though not at full load. The method of starting them was not to excite the motor in the first place, but to leave the motor not excited. The current which was created in the armature induced currents in the field magnets, which tended to assist in starting, and very soon synchronism was obtained. As soon as the motor was going at its full speed the brushes were switched on to the commutator, thereby magnetising the field magnets, and the motor then ran as an alternating-current motor exciting its own field magnets.

At the time that the question of utilising Niagara was very prominently before the world, I had to give my opinion as to what was the best method of transmitting the power. That was in the year 1890. I stated then that, simply adopting machinery which we had thoroughly tested, and which we knew would not fail us, the best method we could possibly adopt was that of using alternating currents, and that the best way of using alternating currents was to use synchronising motors, such as the Mordey machine. I specially mentioned the Mordey machine because I had found it work so extremely well under all circumstances. I confess that I had had, perhaps, some special advantages which enabled me to see that this was really so satisfactory a machine for transmitting power over this distance. I had not only had special opportunities of testing very thoroughly the Mordey machine, and the Siemens machine, and the Ferranti machine, but I had also an opportunity of testing the Tesla machines, which were made at Pittsburg; and I felt at that time that the Mordey machine was the one which was most suitable for the purpose. Our object at that time was simply to transmit power. The distribution of the power through the town was of secondary importance. But even then I proposed to distribute the power through the town to large factories, which require to have their machines running all day simply by the alternating current, transformed down from 10 000 volts to 2,000 volts, because you cannot safely carry—or, at all events then, I could not recommend that you could safely carry—10,000 volts through the streets underneath the ground. You would have it then of 2,000 volts going to the large factories. For smaller shops and places, the proposition was to convert our high-tension alternating current into continuous current outside the town, and then carry it into the town for use with small continuous-current motors. That was the solution at that date.

Seeing that the rotating-phase motors have been such an enormous success, you may ask me why it was that I did not then consider that the rotating-phase motors were the best. I am not sure that they would be the best even with the experience which has come since; but at the time I felt that since no motors had been at work on this principle of larger size than a very few horse-power, it would be a rash experiment to go immediately up to machines the smallest of which would be 1,000 h.p. or 2,500 h.p.; and although there was every promise in the Tesla machine, and although I proposed that we should arrange things so as to be able to introduce the Tesla machine as soon as it was made on a larger scale, I did not think that the ordinary transmission over the distance from Niagara to Buffalo ought to be done by means of this machine. And at the present moment I still think that the synchronising motor is the best possible for that purpose. But with the enormous stride that has been made by the genius of Mr. C. E. L. Brown, of Switzerland, in the design of those machines that were shown at Frankfort, there is every reason to believe that we shall have a much greater efficiency.

Let me explain the principle, very briefly, of these rotating phase motors. Here is a diagrammatic illustration—a section of one of these machines, Fig. 2—in which we have four poles opposing each other, and an armature in the middle. The armature is supposed here simply to be wound like a drum armature, and to be short-circuited either at both ends or at the commutator end. In fact, the armature, for all practical purposes, may be supposed to be simply the ordinary drum armature of a Siemens's machine, with the commutator wound round with a bare copper wire, so as to be short circuited at that end. The armature conductors are closed upon themselves, and have no current coming in from the outside. There are two currents coming to the motor from the generating station in different phases. One current circulates round the two horizontal magnets, their polarity, at any moment, being of opposite kind. The other current circulates round the two vertical magnets. The one current is at the maximum when the other current is at the minimum, and one current is always just a quarter of a phase in front of the other current. The consequence of this is, that the magnetism which is induced in the armature will at one moment have a horizontal direction; a little later it will have a vertical direction; a quarter of a period later again, it will again have a horizontal direction, but opposite to what it was before—that is to say, the polarity will be reversed, and so on. It will be seen that, as the magnetism of any pole continually changes

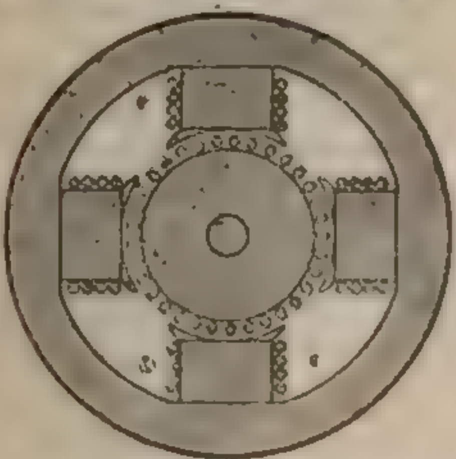


Fig. 2.

gradually from zero to a positive maximum, again through zero to a negative maximum, every complete period, and that the successive poles round the machine differ from each other's condition by an amount corresponding to a quarter of a period; there will be what is equivalent to a continual rotation of the whole magnetic field round the axis of the machine.

(To be continued.)

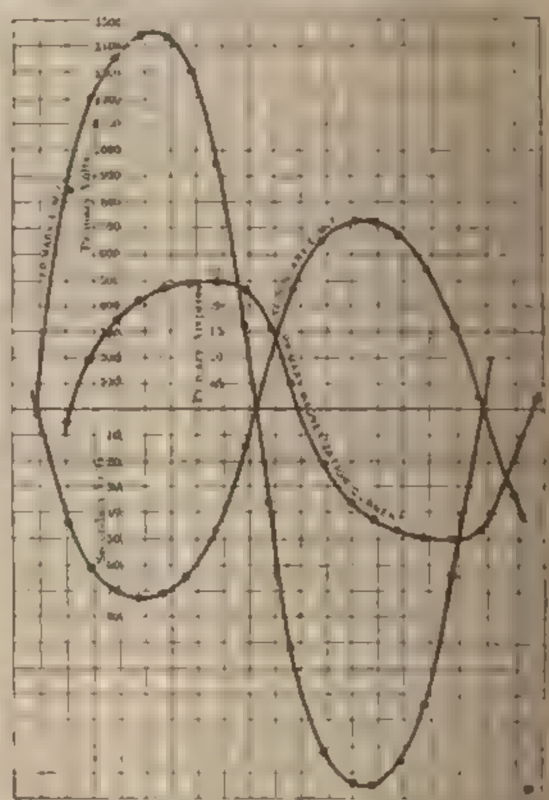
TEST OF A 17,500-WATT STANLEY TRANSFORMER.*

BY HARRIS J. RYAN.

The method employed for testing your 17,500-watt 1,000 × 50 volt transformer for a frequency of 132 periods per second, was as follows:

The power dissipated through hysteresis, eddy currents, etc., was determined by the use of a contact-maker, condenser, and electrometer, as described in the paper on transformers in the *Proceedings* of the American Institute of Electrical Engineers, vol. vii., p. 1. The transformer received current from a Westinghouse alternator at 132 periods per second. This machine was driven by a high-speed 60 h.p. tandem compound automatic engine, that had a fair speed regulation. It was found at the start, however, that the total loss of power in the transformer at full load was in the neighbourhood of but 3 per cent. of the load. On account of the natural drift of the speed of the engine within certain limits, it was not found practicable to measure the total power delivered to the transformer and that given out by it with such a degree of accuracy that the probable error would be less than 1 per cent. This would mean a probable error in the determination of the total power dissipated by the transformer of 33 per cent.

Were there no magnetic leakage in transformers, we would get a measure of the power lost through heating of the primary and secondary conductors by the product of the drop in volts observed on the secondary into the current output of the same. This measure would then be rigidly accurate when the secondary is at work on incandescent lamps and the primary magnetising current is as small as it is for this transformer. Actually, however, there is always some magnetic leakage that increases with the output of each transformer, and lowers the E.M.F. of the secondary by lessening the magnetisation through the same. Since this action results in no waste of power, in ignoring its presence, we shall make an error that counts against the transformer. It is highly probable that in a transformer with a drop in pressure due to load of only 2 per cent. or 2½ per cent., the error thus made against the efficiency at full load will not amount to more than 1½ per cent.



Curves Accompanying a Test of a Stanley 17,500-watt Transformer.

Primary, 1,000 volts; secondary, 50 volts; frequency, 132 P.P.S.; secondary on open circuit; primary effective E.M.F., 1,110 volts; secondary effective E.M.F., 56·0 volts; effective magnetising current, 105 ampere; power lost through hysteresis and eddies, 186 watts. Regulation: Drop in pressure from no load to full load, 2·3 per cent.; efficiency at full load, 96·9 per cent.; at half load, 97·1 per cent.; at quarter load, 96·0 per cent.; at one eighth load, 93·0 per cent.

The drop of secondary pressure due to load was observed by taking simultaneous readings of the effective pressure at the terminals of the primary and secondary when the transformer was loaded with lamps to an output of 17,500 watts, and when it was unloaded. In this way errors due to the drift of the speed of the engine are eliminated.

The accompanying diagram with its curves gives graphically the observations made for determining the power taken up by the transformer with the secondary on open circuit. From the curves of primary impressed E.M.F. and primary current the power lost through hysteresis and eddies in the iron core was determined to be 186 watts, with the pressure at the primary terminals of 1,110 volts. It is desirable to know the power lost at the standard pressure of 1,000 volts. In making this deduction we have assumed that this loss varies as the 1·7 power of the magnetic density in the iron core. The power lost in

* Report made by the Cornell University to the Stanley Electric Manufacturing Company.

the transformer on open circuit at a primary pressure of 1,000 volts is therefore 157 watts.

The drop in the secondary pressure due to load was determined from the following effective primary and secondary pressure readings which are given as the mean of a number of observations.

Full load.		No load.	
Primary.	Secondary.	Primary.	Secondary.
1,077	53·50	1,122	57·03

Reduced to a primary pressure of 1,000 volts:

Full load.		No load.	
Primary.	Secondary.	Primary.	Secondary.
1,000	49·67	1,000	50·83

Drop . . . . . . 1·16 volts, or 2·32 per cent.
Power lost in heating the conductors ... . $1·16 \times 350 = 406$ watts.

The variation of the efficiency with the load is given by the following equation:

$$\text{Efficiency} = 100 \frac{W}{W + H + K W^2}$$

Where W = the output of the transformer in watts;
H = the power lost through hysteresis and eddies in the core,
K depends upon the effective resistance.

Substituting the numerical values of H and K we have:

$$\text{Efficiency} = 100 \frac{W}{W + 157 + \cdot00000132 W^2}$$

The efficiencies at full load, half load, quarter load, and one-eighth load are 96·9 per cent., 97·1 per cent., 96·0 per cent., and 93·0 per cent. respectively. For one 16-c.p. lamp the efficiency is about 24 per cent.

For a determination of the all-day efficiency when the primary pressure is kept up at all hours of the day, it is assumed that this transformer would have a working output equivalent to 17,500 watts for five hours out of every 24. Under these conditions the all-day efficiency is 93·8 per cent.

THE PROBLEMS OF COMMERCIAL ELECTROLYSIS.*

BY J. SWINBURNE, MEMBER.

(*Concluded from page 360.*)

Passing electricity through the vats without agitation has also been tried, but it, again, is of little or no use by itself.

If, however, the skins are agitated and electricity is passed through the bath at the same time, the agitation circulates the liquid into the interstices, and the electric current sends the tannin through the walls of the cells, so that the leather is made infinitely faster than by the ordinary methods. Dr Rideal and Mr Trotter have made numerous and elaborate experiments on electrical tanning. The results of their work are given in the exhaustive paper read before the Society of Chemical Industry. I brought forward this as being probably the explanation during the discussion on their paper, and it agrees entirely with the results they obtained. The best results, according to this theory, would be secured by agitating the hides first to get the liquor into all the interstices uniformly, and then electrolysing to get the tannin into the skin itself; then agitating to refresh the solution in the pores, and then electrolysing, and so on. Messrs. Rideal and Trotter showed that this method does, in practice, give the best results. Leather made in this way also has a better chance of being uniform, because the outside is not acted on perceptibly quicker than the inside.

Tanning by agitation and electrolysis combined seems to have been invented by Messrs. Worms and Balé, and their process has been worked successfully for some time past in France, and in England by the British Tanning Company. Mr. Groth has developed a modification, and is also making leather by this process. Groth's appears rather better than ordinary leather, being more uniform in texture and giving better results when tested for tensile strength. It is shown at the Crystal Palace exhibition this year.

Ozone.

Now that induction coils in the shape of transformers have become commercial, there is every reason to expect that ozone will be made industrially. Mr. Fahrig has already been making ozone commercially in this country. He employs an alternate current which works a transformer which gives a high E.M.F. Air is first drawn through an apparatus which is supposed to separate the nitrogen by diffusion. As nitrogen and oxygen have nearly the same densities, it is hardly likely that much nitrogen is separated. The air is then led through the ozonisers. These consist of piles of corrugated metal plates with sheets of celluloid between them. They are alternatively positive and negative, being connected to the high-pressure side of the transformer. There is thus an alternating discharge from the corrugated electrodes to the celluloid sheets, so that the air is ozonised on passing through.

Messrs. Siemens and Halske employ ozonisers of the more usual form. Two concentric glass tubes are used. One electrode is inside the inner, and the other is outside the outer tube. High-pressure transformers are of course employed, and the air, or oxygen, is partly converted into ozone on its way there. Very little is known about the electrolysis of gases, if such an expression is admissible. The so-called silent discharge seems to work best, but the whole subjects now demands quantitative investigation. The use of glass must involve low efficiency, as glass possesses the property of dielectric hysteresis in a high degree. We also want to know the current density and frequency which give the best results. The arc, and, in fact, many forms of electric discharge, produce traces of nitrogen compounds. It is worth pointing out that if under any commercial conditions nitrogen compounds can be produced from air, there would be an unlimited demand. A works situated on a waterfall would have its power and material provided, and the only cost of production would be the interest on plant, and the wages of a man or two to look after the dynamos.

It has been said that chlorine acted on by the electric discharge is affected in the same way as oxygen. In the first place, chlorine is already quite a strong enough oxidant, and in the second, it is difficult to see how chlorine can form an allotropic modification.

Miscellaneous Processes.

Under this head I have classed a few electrolytic processes whose theory is obscure, and about whose practical success there may be some doubt.

Mr Webster has brought out an electrolytic sewage process. The effluent has electricity passed through it, and this is said to separate the solid material completely, and to kill all germs. Of course, when any sewage containing salt is electrolysed, it produces chlorine or hypochlorites, and these would act on organic matter. Hermite, for instance, has applied his process to the disinfection of ships. This does not seem to be the basis of Webster's process, however, and there seems uncertainty as to what the action is supposed to be, and why the solid particles should be influenced by the current.

The next process is ageing wine and spirits by means of the electric current. Whether there is really anything in this I do not know. Various inventors have brought out methods of ageing liquors by electrolysis. There is uncertainty as to whether the result is produced, and as to how it is produced. Various deleterious alcohols might be oxidised into others, but it is strange that electricity should select just those that give a taste which is unpleasant to the human palate. Mr. Turell uses a direct, while M. de Meritens employs an alternating current.

The sterilisation of milk by electrolysis is another process which is somewhat obscure.

The Electric Furnace.

The idea of using the heat of the arc for producing high temperatures for such purposes as melting iridium is about half a century old. Recently, however, we have had the Cowles furnace, used especially for the reduction of alumina. Properly speaking, this does not come within the scope of this paper, as there is no reason to suppose that electrolysis has anything to do with the reduction of the oxide. By pouring the power from a large dynamo into a carbon resistance, closed in so that the heat cannot readily escape, a very high temperature is produced. Alumina is then reduced by the hot carbon. It may be taken that at lower temperatures such as those produced by ordinary furnaces the affinity of aluminium for oxygen is greater than that of carbon, and that at the higher temperature the reverse is the case. It is not impossible, however, that the carbon in an ordinary furnace is inactive merely because it cannot get into good contact with solid alumina, and that in the Cowles furnace the alumina melts. In any case, there is no reason to suppose there is any electrolytic action going on.

The Cowles furnace is applicable to all processes which demand very high temperatures, such as the reduction of oxides of aluminium, magnesium, calcium, barium, strontium, silicon, chromium, boron, tungsten, and manganese. Of course many of these metals are not at present in demand; but then, it must be remembered, that may be because there has, until now, been no way of making them reasonably cheap. Many, if not all, of these metals have been already obtained by the Cowles process.

It is a question of economy whether the Cowles furnace should not be employed in many other reduction processes which do not require such high temperatures. The furnace is efficient, as the heat is applied where it is wanted, and little is wasted by radiation or convection. We thus have to compare

* Paper read before the Institution of Electrical Engineers.

an ordinary furnace in which the heat is applied badly, and a great deal is wasted because the gases go off at a very high temperature, with a system which begins with an efficient furnace working a very inefficient heat engine and an efficient electrical machine. The electrical furnace will doubtless soon be applied in many cases, especially those which ordinarily involve inefficient furnaces, and retorts which break down quickly or leak.

The manufacture of phosphorus is a good example. On paper the process is simple. Bone ash, or tricalcic phosphate, is not reduced by carbon at ordinary furnace temperatures, so it is treated with sulphuric acid, and converted into monocalcic, or superphosphate. Making this involves making sulphuric acid, or buying it. Acid phosphate is then heated in retorts with carbon, and two-thirds of the phosphorus is obtainable theoretically. If sand is used it acts as a strong acid, or, rather, anhydride, at high temperatures, and all the phosphorus should be obtainable. The retorts, of course, give rise to trouble and expense. Messrs. Readman, Parker, and Robinson, by employing the electric furnace, can deal with mineral phosphates, and require no sulphuric acid. I do not know whether carbon, at the temperature attained in the electric furnace will reduce calcium phosphate to calcium and phosphorus, or whether calcium phosphide is formed. With sand, of course, calcium silicate is formed. One might expect that this would be reduced to calcium and silicon, in which case it would be reasonable to suppose that the operation could be carried on without silica. It has been said that some oxides which can be reduced by very hot carbon when dealt with separately, can form compounds that cannot be reduced if one oxide is strongly acid in comparison with the other. If that is the case, though the lime and silica might be reducible separately, the combination of the two, calcium silicate, might be irreducible. Whether calcium silicate is reducible or not, silica must of course be employed if the phosphate would otherwise be converted into phosphide.

It would be well to see what other reduction processes could be dealt with economically by the Cowles furnace. Doubtless there are many, and Messrs. Parker and Robinson are sure to explore the field pretty thoroughly.

CONCLUSION.

A very few of the possible applications of electrolysis have been described in the foregoing paper, and the labours of many workers have been passed without mention. This was unavoidable. There is also another difficulty in writing such a paper as this. I have not worked at all the processes myself, and have had to rely on published accounts in many cases. Out of every hundred new inventions in electro-metallurgy, ninety are impossible chemically or electrically. If I have ruthlessly cut out a possible or admitted an impossible process, I must ask pardon on account of the impossibility of trying all the processes myself, even experimentally, and must plead that I have been as sceptical as possible.

There are other directions in which electrolysis may play an important part. The improvement of the manufacture of white lead deserves the most careful attention. The Dutch process is unhealthy, costly, and barbarous. The electrolytic manufacture of aniline dyes has received considerable attention. Dr. Goppelsroeder has done a good deal of work in this direction, and samples of silks dyed by electrolytically prepared colours were shown both in the Paris and the Frankfort electrical exhibitions. The extraction of gold from sea water, which is said to contain minute quantities, need hardly be treated seriously. Even if it were possible, such a process would be of no use. All improved processes for obtaining precious metals merely enrich some at the expense of others, and reduce the value of the metals. Obtaining gold more easily would be no good to the community unless it became cheap enough to be used commercially.

NEW COMPANIES REGISTERED.

Akester Electric Syndicate, Limited. Registered by H. H. Price, 9, John-street, Adelphi, W.C., with a capital of £15,000 in £50 shares. Object: to carry into effect an agreement made between W. H. Akester of the one part and P. R. Low, on behalf of this Company, of the other part, for the acquisition of certain patents relating to improvements in electric arc lamps, and to develop and turn to account the same, and as electrical engineers generally. There shall not be less than three nor more than six directors; the first are the first two signatories to the memorandum of association and one other, not named. Qualification, £50. Remuneration, £60 per annum, not divisible.

Carbon Battery Company, Limited. Registered by H. C. Bull, 29, St. George's-road, S.W., with a capital of £10,000 in £1 shares. Object: to carry on business as producers and suppliers of electricity in all its branches; as dealers in magnesium, aluminium, etc.; to acquire certain patents and inventions relating thereto, and to develop and work the same. Registered without special articles of association.

COMPANIES' MEETINGS.

CROMPTON AND CO., LIMITED.

An extraordinary general meeting of the shareholders in Crompton and Co., Limited, was held last Thursday at the [illegible] Mansion House buildings, Mr. R. E. Crompton presiding, to consider a resolution for increasing the capital to £[illegible] by the issue of 22,000 additional ordinary shares of £5 each, to rank as regards dividends and in all other respects pari passu with the existing ordinary shares.

The Chairman (Mr. R. E. Crompton), in proposing the resolution, stated that the additional capital was required in consequence of the growth of the Company's business. He pointed out that the firm of Crompton and Co. originally consisted of Mr. Albright and himself, and that they still held the whole of the ordinary shares. At first sight it seemed that the new issue might be prejudicial to the ordinary shareholders, but after careful consideration they had come to the opposite conclusion. During the last few months they had undertaken very important contracts, and there were others in such an advanced state that they were sanguine that they would be able to keep their works fully employed, and he saw no reason to doubt a continuation of the increase in the Company's business, such as they had experienced in the past. Reference in much the same terms as reported in our last issue was made to the successfully completed electric lighting of the city of Pretoria, South Africa.

Mr. A. F. Albright seconded the motion, which was carried.

BUSINESS NOTES.

Dundee. The tender for switchboards for Dundee must be sent in by Saturday, the 22nd inst.

Burnley. Next Wednesday is the last day for receiving the tenders for the Burnley electric plant.

Toxteth Park. –The Toxteth Local Board have been discussing the details as to the proposed electric lighting of the district.

York. Tenders for lighting plant for York are required by Nov. 21. Particulars of the town clerk, York; fee, two guineas.

Blackpool Telephones. Serious complaints have been made as to the working of the telephone service to the Blackpool [illegible] station.

Lamp Columns. Messrs. Jukes, Coulson, Stokes, and Co. have recently received a large order for lamp columns at £5 [illegible] per ton.

Western and Brazilian Telegraph Company. The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £3,851.

Direct United States Cable. – The Directors have declared an interim dividend at the rate of 3½ per cent. per annum for the quarter ended September 30, payable on the 24th inst.

Waterford. The streets of this city are once more lighted by gas and an end is thus made, at least for the present, to the plucky attempt to oust gas in favour of electric light for the street lighting.

Hornsey. The Hornsey Local Board has declined to allow the County of London Electric Lighting Company to carry out electric lighting in the parish, being of opinion that it would not be successful.

Central Stations. Besides the central station for Coatbridge (9,000 lamps capacity), Messrs. J. E. H. Gordon and Co., Limited, have secured the contract for the supply of central station plant for Windsor.

Elihu Thomson Patents. –Mr. Elihu Thomson is desirous of selling or exploiting the French patents for dynamos, regulators and meters. His agent is M. Emile Barrault, 58 bis, Chaussée D'Antin, Paris.

The Tramways Institute. This institute has removed from [illegible] Coleman-street to large and convenient premises at Broad-street Station Buildings, 18, Eldon-street, E.C., with entrance also at 19, Finsbury-circus.

Molesey. At the last meeting of the Local Board [illegible] proposals, the terms of which have not yet been made public, on the subject of electric lighting, was referred to the General Purposes Committee.

Bath. A meeting of the Bath Sanitary Authority has been summoned for 25th inst., amongst other things, to receive and consider a report from the Electric Lighting Committee adopted by the Surveying Committee.

Manchester. The increase in the necessity for lighting facilities is so great that it is proposed to spend £[illegible] in extensions of the gas works. The electric light station, when it gets going, should have plenty of scope for developing demand.

Road Breaking. The Bournemouth Electric Light Company have written to the Town Council to ask them to make a reduction in the charge for repairing roads broken for the laying of cables, but the Council are not prepared to make a reduction.

City of London Electric Lighting Company.—Letters of allotment and regret in respect of the issue of £200,000 6 per cent. cumulative preference shares were posted on October 6.

Electric Bells at Church.—A set of electric bells to ring in all parts of the house has been fitted to Spurgeon's Tabernacle. All strangers are kept standing, and five minutes before service the signal is given, followed by a rush to the best seats.

Watford.—The Watford Board of Guardians had before them the terms of the Watford Exchange Telephone Company for placing the workhouse on the exchange, but the Guardians did not think the additional convenience would warrant the expense.

Electric Calls for Poole.—At the special meeting of the Poole Town Council last week the Fire Engine Committee recommended, and it was agreed to, that the borough surveyor should prepare specifications as to the repair and maintenance of the electric call apparatus.

City and South London Railway Company.—The receipts for the week ending October 9 were £859, against £747 for the same period last year, or an increase of £112. The total receipts for 1892 show an increase of £995 over those for the corresponding period of 1891.

Dover.—Alderman Adcock, at the last meeting of the Dover Town Council, said he thought the Council's provisional order would expire before the agreement with the Brush Company was completed. The Mayor said he believed that there had been real cause for the delay, but perhaps it would be best to waken them up.

Electric Fire Alarms for Liverpool.—The Liverpool Watch Committee, at the weekly meeting on Monday, decided to recommend the City Council to adopt, at the monthly meeting tomorrow, the principle of electric fire alarms for the city, a system which has worked efficiently in London, Glasgow, and other large centres.

Taunton.—The following figures are given by Mr. William Porter, in answer to request, with reference to the loss at Taunton electric works during 1891. Working expenses, £1,867; income from rent, £1,251; loss on year's working, £376. The figures have been already published, he says, in the report of the Joint Committee.

India.—The *Indian Engineer* is intending to issue a thin paper copy of their paper at a cheaper rate including postage. Subscribers have the advantage of being able to obtain free of charge any special information they may require from the Calcutta or London offices. The address of the latter is 1 and 2, Victoria-mansions, S.W.

Aberdeen.—The Gas Committee reported that the total area of the ground purchased by the Council for the building for gas and electric lighting was 1,624½ square yards, of which they proposed to allocate 581½ square yards for gas purposes, and 1,043 square yards for electric lighting purposes, the total feu-duty being £10. 4s. 2d. The report was adopted.

Leeds Tramways.—Some time must yet elapse before the negotiations for purchase by the Leeds Corporation of the tramways can be settled, awaiting the decision of the High Courts on the price to be paid. As it is known the authorities look well on electric traction, their purchase, when it occurs, may influence the adoption of this method for these lines.

Martiny, Limited.—A company has been formed with the formidable title of "Société Française de Caoutchouc, Amiantes et Câble (Martiny, Limited)." This combination comprises three companies, whose names appear in the compound title. The capital is five million francs, and the London office is 37, Lombard-street, with works and showrooms in France.

Circus Lighting.—A speciality has lately been made by Messrs. Blakey, Emmott, and Co., the well-known electrical engineers in Halifax, of circus lighting. One circus having been fitted with engine and dynamo for arcs and incandescents, the rest have followed suit, and quite a number of "Original Wombwells" have been fitted up, with much satisfaction to the proprietors and the public.

Wigan.—The inhabitants of Wigan have not taken up the Gas Committee's electric lighting scheme very enthusiastically, the chairman reporting last week that only eight or nine had as yet filled in the circular affirmatively. The committee do not see their way to spend £30,000 in a central station with such small encouragement. Perhaps private endeavours would result in a better result.

Burton.—At the monthly meeting of the Burton Town Council, Alderman Lowe, in moving the adoption of the Gas and Electric Committee's report, said that the Board of Trade had approved the scheme for lighting a portion of the town by electricity, and the manager had received instructions to prepare the necessary plans. The committee would now push on the work as fast as possible. The motion was agreed to.

Sutton (Surrey).—Tenders are invited for lighting (at per lamp) for lamps of one burner and for lamps of two or more burners for the public lighting of their district, by gas or other illuminant, for one year from Nov. 1 up to Nov. 1, 1893, for the Sutton Local Board. Tenders should be sent to Mr. Thos. D. Pettiver, clerk, Sutton, marked outside "Tender for Public Lighting," by 12 noon on 19th inst.

Chiswick.—The Board of Trade have written to the Chiswick Local Board with reference to the contract for the supply of electric light, stating that the Board would lose no time in considering the draft agreement with respect to this matter which had been submitted by the local authority. Some delay would, however, arise through the absence of their counsel in Scotland. The clerk was instructed to write protesting against the delay.

Metal Cutters.—The bandsaw machines of Messrs. Greenwood and Batley, Leeds, are exceedingly useful for the quick trimming of metal forgings for dynamos and engines. Instead of laboriously boring or planing out a crankshaft or other large slot, the new method consists of drilling a hole, running round a metal band-saw, and in a wonderfully short time a solid lump is cut out, and there only remains to trim up the edges in the planing machine.

Vaudeville Theatre.—Messrs. Mather and Platt, Limited, of 16, Victoria-street, have carried out the lighting of the Vaudeville Theatre, the number of lights in the building being 260 lamps of 16 c.p. in the stage, 130 lights in the auditorium and dressing-rooms, and 10 100 c.p. lamps in the central dome light. The whole of the contract, including the supply of fittings, resistances for stage lights, etc., has been completed in the short time of 12 days.

Hammersmith.—A lively discussion took place at the Hammersmith Vestry meeting last week on the subject of electric lighting. The Electric Lighting Committee reported that having carefully considered the area throughout which the Vestry is to lay the distributing mains within a period of two years, recommended that the Vestry should schedule certain streets. The localities named were the cause of the discussion, and in the end two other roads were added to the list.

Rangoon.—At a Municipal Sub-Committee meeting held at Rangoon, India, on the 13th September, an offer was read from the Edison-Swan Company to light up the town for the same price as now paid for oil lighting. The same number of electric lamps as there are now oil lamps would be used with three times the illuminating power. A concession of 30 years is asked, with a guarantee of 5 per cent. of the net profits to the town. The engineer is to report upon the project.

Blackburn.—At the monthly meeting of the Blackburn Town Council, Alderman Eastwood said he noticed there was a resolution for the purchase of a plot of land in Jubilee-street as a site for an electric light generating station. Whilst he had no objection to offer, he should like the chairman of the Gas Committee to promise that no chimney should be erected on that site. He thought the difficulty could be met by erecting the chimney in the gas company's yard on the other side of the street.

Companies of the Month.—The following electrical companies were registered during the past month:

Carbon Battery Company, Limited, £1 shares	£10,000
Electro Alkali Company, Limited, £10 shares	160,000
London Health Electrical Institute, Limited, £1 shares	10,000
New Electro Metallurgical Syndicate, Limited, £1 shares	10,000
New Electricity Supply Company of Croydon, Limited, £5 shares	40,000

Derby.—The Electric Lighting Committee of the Derby Corporation have resolved to recommend to the Council the acceptance of the following tenders in connection with the scheme for the supply of electric light in the borough, recently sanctioned by the Council: For the buildings, Messrs. Walkerdine and Co., £3,870. 4s. 3d., and for the engines and dynamos Messrs. Siemens Bros., London, £10,781. The engineers are Sir Frederick Bramwell and Mr. Harris, and their estimates were for the buildings £5,606, and for the engines, etc., £10,500.

Mill Lighting.—There is a large corn mill situate in the Waterloo Bridge-road, known as Seth Taylor's, which is a striking building, one peculiarly fitted, it would seem, to be lighted by electric light. Some four or five years ago it was burnt down, if we remember rightly, and since then it has been the stock target for electrical estimates. Many good firms have made overtures, but it has fallen to the lot of Messrs. Easton and Anderson at last to secure the contract. A large notice is now affixed, stating that a complete plant is being put in by the Erith firm.

Kelvinside.—A correspondent says that instead of the Kelvinside Company having chosen an ornamental design of chimney-shaft fitting to the position, it seems that they had deliberately chosen the most ugly and offensive pattern—coarse and square. The chimney question is indeed, a raging one, it would seem, for this correspondent says it will have the effect of preventing him taking the electric light. The secretary has written to say that the best advice has been taken, and that the directors, recognising the weight of the objection, have given orders that 40ft. shall be taken off the height, the saving in cost to be applied to making the shaft more ornamental.

City Commission of Sewers.—A meeting of the City Commission of Sewers was held on Tuesday at the Guildhall, Mr. Alderman Treloar presiding. A report was brought up by the Streets Committee relative to accounts from the City of London Electric Lighting Company, amounting to £1,211. 5s. 7d., for lighting certain of the public ways of the City up to Midsummer Day, and recommending that the accounts should be paid, without prejudice to the contracts and provisional orders. This was agreed to. An application by the City of London Electric Lighting Company for permission to use some of their pipes for telephonic purposes was referred to the Streets Committee for consideration and report.

Shoreditch.—The annual report of the Shoreditch Vestry, which is just issued, mentions as one of the most important items the acquisition of the monopoly of the electric lighting of the

[illegible] lighting and [illegible] experimental stage to that of [illegible] regarded as the luxury of the rich, [illegible] a necessity for the poor owing [illegible] advantages which electric light possesses over [illegible] of illumination."

Canterbury. – The Electric Light Committee of the Canterbury Town Council reported at their meeting last week that a letter had been received from Messrs. Mewill asking that various alterations should be made in the deed of agreement and the deed of transfer. The committee were unable to agree to certain of the suggested alterations and the town clerk had been directed to inform Messrs. Mowil that the drafts as they now stand were approved by Mr. Moulton, Q.C., to whom they were sent at Messrs. Mowil's suggestion. The Mayor said he had only to state that they were for once unanimous in their report. No reply had yet been received from the Brush Company. The matter had not dropped. The minutes were confirmed.

Middlesbrough. The sub-committee's attitude on the electric lighting question is that a provisional order ought to be obtained which would enable the Corporation to maintain the ground for two or three years during which time they could either carry out the work or pass their powers to a private company. The suggestion by Mr. Forbes that it would be better to allow a company to undertake the supply on conditions of repurchase after a certain number of years was not thought desirable. Mr. Taylor is of opinion that the Corporation should undertake the work at once, but the ownership by the town of the gas works, and the considerable revenue derived therefrom (which might suffer) is the real obstacle in the way of immediate adoption of a scheme.

Ravensthorpe. – At the meeting of the Ravensthorpe (Yorks.) Local Board Mr. J. H. Tattersfield read a resolution passed at the ratepayers' meeting urging upon the Local Board the desirability of promoting the introduction of the electric light on account of the heavy price paid for gas and that all efforts up to now towards obtaining a reduction had proved futile. He urged the introduction of the electric light, and was not in favour of buying the gas plant. Mr. Townend assured the deputation that the Board had not lost sight of lighting the township with electricity. The matter had been before the Board some 18 months. They had been to see an installation, and he might say the members had it in their minds to light Ravensthorpe with electricity, but as electric lighting in their minds was yet only a matter of experiment, and was likely to develop, they thought it wisest to wait.

Crompton and Co., Limited. Crompton and Co., Limited, announce the issue of 12,000 ordinary shares of £5 each, of which it is not proposed at present to call up more than £1 per share. The Company was formed in July, 1888, to acquire and carry on the business of electric light engineers, founded by R. E. Crompton and Co., of Chelmsford and London. The capital of the Company was £300,000 in 30,000 7 per cent. preference shares of £5 each, of which 25,916 have been subscribed for and allotted, and 30,000 ordinary shares of £5 each, of which 8,000 have been allotted as fully paid up. The business, since it was taken over by the Company, has very largely increased, and the object of the present issue of shares is to provide the further working capital required to continue the development of the business, and to facilitate the carrying out of certain large contracts which have recently been secured, and of others which are in negotiation.

Brazilian Submarine Telegraph Company. The report for the half-year ended June 30 states that the revenue amounted to £111,870, and the expenses to £29,557. After providing for debenture interest, sinking funds, and income tax, there remains a balance of £68,690, to this is added £19,883 brought forward, making £88,573. A quarterly interim dividend, amounting to £19,500, has been paid, and £40,000 transferred to the reserve fund, increasing that fund to £379,714. The Directors now recommend a final dividend of 3s. per share, making a total dividend of 6 per cent. for the year, and a bonus of 1s. per share, both tax free, which together will amount to £26,000, leaving a balance of £3,073 to be carried forward. The dividend and bonus will be payable on the 20th inst. On July 31 last £15,800 was transferred to pay off the 158 bonds of the 1884 issue drawn for redemption in April last. This reduces the debenture debt to £111,400.

Accrington. – At the Accrington Town Council meeting last week some detailed information as to the proposed electric lighting station came out in the discussion. The committee intended to use the land on which at present were Higham's baths, the area being 2,000 yards and the price 2s. a yard. The town clerk said they had not yet entered into an agreement with Mr. Higham, and the Mayor said the matter was not completed in any way. Councillor Sparke said their determination was simply to get specifications from Mr. Shoolbred, but they were not pledged to go on with the scheme. The Council have resolved that Mr. Shoolbred be instructed to prepare plans, estimates, and specifications for the construction on the above site of a central electric lighting station, with two engines of 40 h.p. each for a commencement, and the necessary station instruments and distributing plant, previous to application being made to the Local Government Board for their sanction to the borrowing of the necessary amount. This amount, the clerk stated, was rather under £10,000.

Cost of Electric Traction. – The following circular letter is being issued by the Electric Power Storage Company to the chief tramway companies in Great Britain, and is the best possible answer to the criticism that has lately been made on the expense for maintenance of batteries and electrical gear of tramcars: "Dear Sir, – We beg to call your attention to the fact that we are now prepared to negotiate for the working and maintenance of approved tram lines equipped with self-contained or storage electric cars. The terms under which such working and maintenance can be contracted for necessarily vary with local conditions, but the maximum charge would be 66 per cent. of the gross traffic receipts. You will readily note that such an undertaking should and does constitute the most effectual guarantee of perfection of service, and we shall be pleased to discuss the matter further with you at any time." We dealt with this offer in a recent leader, and trust this offer from a responsible company like the E.P.S. Company will have a practical and immediate response.

Barnet. The Finance Committee reported at the last meeting of the Barnet Local Board that the item for the [illegible] costs of a provisional order for electric lighting was eliminated. With regard to the clerk's bill in connection with the [illegible], it was resolved that Mr. Poole's agents be asked to return the original list of Mr. Moulton's fees, and also that the bill of costs be taxed in the Court of Queen's Bench, and that Mr. [illegible] appear on behalf of the Board. The clerk read the following letter from the secretary of the Local Government Board: "Sir, – I am directed by the Local Government Board to acknowledge the receipt of your letter of the 10th ultimo, relative to the application of the Barnet Local Board for sanction to borrow money to defray certain legal expenses incurred by them, and I am to point out that the loan of £500 for legal expenses was sanctioned in 1878 because those expenses were incurred in connection with the execution of permanent works. In the present instance the expenses were not so incurred, and under these circumstances no loan can be sanctioned by the Board in respect of them under the Public Health Act, 1875."

Bowness. – At the monthly meeting of the Bowness Local Board the clerk read a letter received from Mr. Fowkes regarding a proposal to introduce the electric light into the district, and stated that he had prepared the draft of an agreement between the Board and R. H. Fell and Sons, Limited, which had been submitted to the latter's solicitors in London who, to make it satisfactory to themselves, had put in two or three slight alterations. Having read the draft, Mr. Gatey stated that Mr. Fowkes had also made a communication respecting a proviso which enabled the Board, if they thought proper, to take over the electric lighting at a stipulated rate at the end of 14 years, which he considered too short a time, and suggested that it should not be less than 21 years. After some discussion, Mr. Holland proposed that "subject to the terms embodied in the draft agreement between the Bowness Local Board and R. H. Fell and Sons which then lay on the table, the Bowness Local Board approve of the same and recommend that the Main Roads Committee accede to the request made for permission to lay a main electric cable down beneath the main roads in the district." Mr. Westlake seconded the motion, and it was carried.

Portsmouth. At the Portsmouth Town Council meeting last week the Electric Lighting Committee submitted tenders for the erection of the building for the electric lighting station and recommended that the tender of Mr. T. W. Quick be accepted. The prices were: Mr. W. W. Evans, £10,270; Mr. T. P. Hall, £9,425; Mr. R. W. Learmouth, £8,367 5s. 7d.; Messrs. E. and A. Spriggings, £9,300; Mr. T. W. Quick, £8,400. The town clerk read two letters from Mr. W. W. Learmouth, one of the contractors, complaining of the unfair manner in which he had been treated by his tender – the lowest – being passed over through a slight informality. The amounts of the bonds, he owned, were not on the tender, but they could have been easily ascertained by referring to the bill of quantities attached. A second letter pointed out that in Mr. Quick's tender the sureties' names were not written by the sureties themselves, and he submitted that this was a more fatal informality than his. Alderman [illegible], chairman of the committee, pointed out that the names of the sureties appearing on Mr. Quick's tender were put in with authority. The reason the work was not started before, he said, was that the Local Government Board had been so tardy in sanctioning the borrowing of the money. Mr. Quick's tender was accepted.

Ardrossan Harbour. The installation of the electric light at Ardrossan Harbour has been completed. It consists of 17 arc lamps of 3,000 c.p. each, distributed around the harbour and in the coal elevators and Caledonian Railway Station. The dynamo and engine are fixed in the hydraulic engine house. The engine is specially adapted for electric lighting work, and is of the vertical high-speed type, with closed crank chamber, with a cylinder 9½in. diameter by 9in. stroke. The dynamo is a series-wound machine, giving an output of 15 amperes, at an electrical pressure of 1,000 volts, which is equivalent to supplying 20 lamps of 3,000 c.p. each, or a total of 60,000 c.p. The dynamo is mounted on adjusting rails, and is driven by one of Hendy's patent belts from the flywheel of the steam engine. The conductors to the various lamps are carried overhead, and the method adopted is an exceptionally secure one. In view of the comparatively high electric pressure, the conductors are highly insulated throughout with vulcanised india-rubber, and these conductors are suspended by leather thongs from steel suspending wires stretched between insulators from pole to pole, this arrangement giving perfect safety from accident through short circuit. The lamps are of the double carbon type, and are capable of burning for 16 hours without adjustment. Each lamp is provided with a double-pole cutting out switch. The lighting has been found a great boon to passenger steamers receiving and disembarking passengers, and in

facilitating the rapid loading and discharging cargoes during the night. The work has been carried out, as we stated last week, by Messrs. Mavor and Coulson, of Glasgow, under the superintendence of Messrs. Strain, Robertson, and Thomson, the Harbour Company's engineers.

Manchester.—At the monthly meeting of the Manchester City Council held last week questions were asked by Mr Batty and Mr Smallman, who wished to know, on behalf of ratepayers who had completed their installations, when the electric light would be available, but so far, Sir John Harwood said he was afraid his answer to the question must be in a somewhat stereotyped form namely, that there were difficulties in the way that the Gas Committee did not at first anticipate. One of the difficulties was the erection of a large chimney, the completion of which could not be hurried without risk to the stability of the structure. Another was that a large room was being lined with glazed bricks, and there was delay in the supply of material, because they were bound to have the bricks from one maker in order to have them all of the same colour and quality. He might add, also, that everything was being done that could be done, and there was no unnecessary delay. The mains were being laid in the streets in a very efficient manner, and the wires would be ready by the time of the completion of the other works. Possibly that would be soon after Christmas, he was inclined to think it would be in March or April. In addition to the matters he had mentioned there were conflicting interests between contractors which kept back the work at the electric light station, but no body of men could give more attention to the operations than was being given by the Gas Committee.

Blackpool. Mr Councillor Pearson, at the Blackpool Town Council meeting last week, in moving that the tender of Messrs. Hammond and Co should be accepted, said the amount of the tender originally was £18,978. The committee had, however, at some of their meetings considered it advisable to include certain extras for oil pumps, water gauges, and Hopkinson's valves, so that the total amount of the tender would be £19,119. 15s. There were deductions from this amount in accordance with an arrangement by the committee. For instance, the committee had resolved that they would be protected by having a well known type of boiler, and it was arranged that one of Messrs. Galloway's manufacture should be supplied to them, instead of a multitubular boiler as at first suggested. This reduced the tender to £18,709. 15s. This amount did not include the building nor the junction boxes, etc., all of which would have to be completed at the expense of the Corporation, but they anticipated that the total expense would come well within the amount which it was intended to borrow upon the sanction of the Board of Trade being obtained viz., £26,000. If they succeeded in carrying out their scheme for the amount of money named, the committee would consider that they had got exceedingly good value for their money and a satisfactory result of their labours. The station would be equal to generating current to light at one time 6,620 incandescent lamps of 8 c.p. each, besides lighting 110 arc lamps of 2,000 c.p. each for illuminating the Promenade. The gas department were prepared to manage the old part of the electric lighting until the committee had carried out their scheme, and they were, moreover, prepared to assist the new scheme to their fullest extent in the future. He added that arrangements had been made whereby the same dynamos would drive the tramways during the day and generate the current for the illumination of the town at night. The minutes were carried.

Whitehaven.—At the monthly meeting of the Whitehaven Town and Harbour Trustees the minutes of the Electric Lighting Committee were read. The minutes showed that on September 6 Dr. Hopkinson's opinion had been asked on the tenders of Messrs. Galloway, Limited, and the Lowca Engineering Company for boilers, and a second tender was invited from Messrs. Galloway for two Lancashire boilers of equal capacity to the two Galloway boilers specified by Dr Hopkinson. On September 14 the committee further considered tenders for the supply of boilers, and recommended that the tender of the Lowca Engineering Company for the supply of two Lancashire boilers be accepted, that the clerk write to Messrs. Ramsay Bros., and call their attention to the letter to them from the town surveyor of the 10th inst., and give them notice to desist from any interference with the powers granted to the trustees under the Whitehaven Electric Lighting Order, 1891. On 20th September, Dr Hopkinson attended the meeting. The solicitor was instructed to prepare draft agreements to be entered into between the trustees and the various contractors for the electric lighting plant and on 28th September the committee recommended that the offer of the Boiler Insurance and Steam Power Company, Limited, of the 27th inst., to inspect the two boilers during construction at the Lowca Engineering Works, be accepted. After reading these minutes, the chairman, Mr J. G. Dees, J.P., proposed as a specific resolution that the following tenders in connection with the proposed scheme for electric lighting be accepted, subject to the sanction of the Local Government Board being obtained for the loan applied for viz., The tender of Messrs. Ramsay Bros., Whitehaven, for iron and steel work for foundations of engines and dynamos in sewerage engine house, the tender of Messrs. Willans and Robinson, for four sets of Willans engines and Crompton dynamos, the tender of the International Okonite Company, Manchester, for conductors; and the tender of the Lowca Engineering Company for two Lancashire boilers. The motion was seconded by Mr Pattinson. The Chairman said there had been a pretty large competition. The tenders were invited from certain firms that were selected as the best possible firms to do the work that was required. Most of these things were specialties, and only made by certain firms; so that it was no advantage to advertise generally. The resolution was put and carried. The minutes of the Electric Lighting Committee were then put and carried. Mr Bowman objected to a further sum than the £14,000 being asked for as was intended, and said he would raise the question again at another meeting.

Accrington Co-operative Society. This society have had before them the report of their committee on the advisability of the introduction of electric light. The chairman of the society said they were aware that the Accrington Corporation had obtained power to supply the electric light, and the society had been asked if they would become customers if the Corporation laid down plant. The committee were given to understand the price from the Corporation would be from 6d. to 9d. per unit. At that price it was doubtful if any saving could be effected as compared with gas at 2s. 7½d. per 1,000ft., and the committee decided not to recommend the society to become consumers. They then determined to make a full enquiry, and a sub-committee of four, along with the manager, was appointed to visit places where the light was in use. The result was that they had decided to ask the members' permission to proceed with the work. They viewed the question from three standpoints (1) its advantage over gas as an illuminant, (2) from a sanitary point, and (3) its cost. For the first, it had a decided advantage over gas consumed in the ordinary way, for the second, there was hardly any comparison, the advantage being so much in favour of the electric light, in one case the top room of a large building was almost as cool as the bottom room, and the manager told them the electric light had saved them scores of pounds in depreciation, and with regard to the third, the society visited supplied them with full details of the cost. These showed that the light was produced at less cost than gas as estimated by the number of lamps in use against the number of gas burners. With such a favourable report the committee felt warranted in asking for estimates, and seven firms all more or less local had responded. There was considerable difference in the amounts, but the figures for laying the plant ready for work were about £1,200. The estimated depreciation on the buildings used was £10, and on plant at 10 per cent. £120, while on coal, oil, sundries renewals, and wages, about £137, or a total expenditure yearly of £267. The gas bill for 12 months at 2s. 7½d. was £272; at 3s. 0½d. it would be £315, and nothing was credited in those figures for lessened depreciation in stock, better light, nor gas fittings. The committee thought they would be justified in making the venture. The motion to do so was carried unanimously.

Londonderry. A special meeting of the Londonderry Corporation was held on Tuesday, the Mayor (Dr. MacCullagh, J.P.) presiding, to consider a report of the Lighting Committee in favour of proceeding with the introduction of electric lighting into the streets of the city. Councillor Magee, chairman of the Lighting Committee, moved the recommendation that the public lighting of the city by electricity under the provisional order of 1891 be proceeded with, and that a sum not exceeding £12,500, already voted by the Council on December 16, 1890, be applied towards establishing and completing the public installation. Councillor Magee reminded the Corporation that they had been first driven into action in the matter by the appearance of the House-to-House Company with a request that they should get powers which the Corporation thought should be retained in the hands of the citizens' representatives. The Corporation had got a provisional order, but, in case they failed to put it into force, the Board of Trade might transfer the powers which it gave them to any public company so applying. The passing away of these powers from the Corporation to a company would be disastrous, and leave the city at the mercy of such electric company and the gas company, who might combine to give the city a starved light. The new light could be introduced without any additional taxation. The scheme was to substitute electric lighting for gas throughout the city. The gas lamps cost the Corporation over £2,000 a year, and this sum alone would be more than sufficient to cover the initial cost of the proposed installation. Not only would that £2,000 cover interest on capital, but it would provide a sinking fund to pay off their loan in 35 years, in addition to leaving a margin of profit calculated at £200 a year. The arc lamps would have 2,000 c.p. The public lighting would be by arc lamps worked by continuous currents at high pressure placed on posts at an elevation of 25ft., and arranged on two separate circuits in each street, so that half the light could be extinguished at a time, and that failure was practically impossible. Where any street was too small for arc lamps, small incandescent lights would be substituted. They proposed to follow the system which had proved so successful in St. Pancras and Dublin. Councillor Turner seconded the motion for the adoption of the recommendation, and said the citizens were anxiously looking for the introduction of the electric light. Alderman M'Learn, J.P., approved generally of the scheme, but was disposed to move as an amendment that the question of the eminent engineer to whom the plans would be submitted should be left open to the Council in committee to discuss. The report bound them to Dr. John Hopkinson. He also thought they should not be bound to accept the particular site recommended by the committee for the generating station. Councillor Pollock, J.P., asked was it necessary the site should be near the quay. Mr Blake, the electrical engineer under whom the Corporation have proceeded, was in attendance. He replied it was certainly necessary. If they had not the benefit of the river water for condensing purposes there would be such a large quantity required that the water supply would be interfered with. Several members urged some delay, with the object of getting the latest advice.

Eventually the report was amended in the direction urged by Alderman McLaren and unanimously adopted, the whole Corporation to be a committee to carry out the resolution.

Electrical Trades' Union Demonstration. —On Saturday, says the *Manchester Examiner*, a demonstration took place at Belle Vue, in this city, of the Electrical Trades' Union, a labour organisation which is composed of workmen who follow the following occupations in connection with electrical industries: Dynamo winders, erectors and tenders, installation linesmen and wiremen, indoor and outdoor, battery and accumulator makers, fitters and inspectors, telegraph and telephone wiremen and linesmen and labourers who are employed in either telegraph, telephone, or electric light construction and maintenance. About 200 sat down to tea, and a short meeting, which was afterwards held, was presided over by Councillor G. D. Kelly, secretary of the Manchester and Salford Trades Council. A number of letters of apology for non-attendance were read from members of Parliament and other gentlemen who expressed their sympathy with the objects of the union. The chairman said he knew of no trade in which a union was required more than in their particular trade. His idea of a trades union and the benefits that should come to the men composing it was advanced wages, reduced hours, and better conditions of labour altogether. Some of the men who composed the new unionism regarded a trades' union simply as a fighting machine. That was not his view. His impression was that if they wanted to gain any lasting benefit it would not be by pulling off their coats and fighting the employers, but by going on safe and constitutional lines, and with the greatest respect and courtesy approaching their employers to bring about those changes which they desired to see effected. They must not be led away by plausible talk into taking steps that they were not prepared to take, but before advancing they must always be sure of their ground, and be in a position to step back again if it was necessary. Another function of trades unionism was that of encouraging each other, so that each man should not live selfishly for himself. He noticed with pleasure, and as one of the signs of the times, that a gentleman who was an official of the company which employed many of those he was addressing was present. He urged the men to cultivate a good feeling between their officers and themselves, and so conduct themselves that the officers would respect their union. He was glad to see the efforts which were being put forward for the organisation of female labour. Such an organisation was required. He knew of one place in the city where if a woman earned 6s. a week there were deductions and fines to such an extent that it was rarely that she could get out of the place with more than 4s. 9d. And that sum meant 10 or 12 hours work a day for six days a week. How could a woman live respectably on such a pittance as that? When a woman's labour came into competition with that of a man the latter's wages always went down, but they ought to see to it that where such competition was unavoidable the woman got as much as the man. They were trying to start a women's trade union, and he invited all women workers, no matter what their occupation was, to join it. On the motion of Mr. H. Burgess, seconded by Mr. C. H. Ormsby, a resolution was adopted calling upon all electrical trade workers to join the union. A vote of thanks to the chairman terminated the proceedings.

PROVISIONAL PATENTS, 1892.

OCTOBER 3.

17593. **An improved detachable electric lamp jointing for removable lamps for shop fronts and similar situations.** William Richard Wynne, 3, St. Nicholas buildings, Newcastle-on-Tyne. (Complete specification.)

17600. **A new or improved automatic electric switch.** Francis Harrison, 54, Fleet street, London.

OCTOBER 4.

17643. **Improvements in electric switches.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

17647. **Improvements in magneto-electric appliances.** Harry Hylton Foster, 76, Chancery-lane, London. (Complete specification.)

17653. **An improved process for treating cups, separating partitions or diaphragms, used in electric batteries or electrolytic apparatus.** Anton Joseph Lehman, Monument chambers, King William-street, London.

17691. **Apparatus for the cutting of glass by electricity.** Leon Havaux, 323, High Holborn, London.

OCTOBER 5.

17698. **A new or improved polarised electrical indicator.** Henry Frederick Lewis and Harris Henry Eley, 2, John street, Bristol.

17700. **An improvement in electric arc lamps.** Edwin Charles Russell, Jeffrey's-square, London.

17717. **Improvements in connection with electrical machines and coin-freed mechanism therefor.** Henry Johnson Avery and Eugene Morand, 13, Temple-street, Birmingham.

17718. **Improvements in or relating to electrical and mechanical telephone receivers.** Henry Rose, 46, Lincoln's-inn-fields, London.

17743. **Improvements in arc electric lamps.** Ernest de Pass, 78, Fleet-street, London. (Louis Bardon, France.) (Complete specification.)

17751. **A door lock switch for electric lights.** George Frederick Redfern, 4, South-street, Finsbury, London. (Charles Green, Canada.) (Complete specification.)

OCTOBER 6.

17774. **Improvements in dynamo-electric machines and in their applications to secondary battery installations.** Edward Woodrowe Cowan and William Paul James Fawcus, Brackland, Vicarage-lane, Bowdon, Chester. (Complete specification.)

17826. **A method of transforming alternating electric currents of any tension into continuous currents also of any tension, and conversely and apparatus for that purpose.** Maurice Hutin and Maurice Leblanc, 28, Southampton buildings, Chancery-lane, London.

17855. **Improvements in electrical distribution.** Thomas Tomlinson, 24, Southampton buildings, Chancery-lane, London.

OCTOBER 7.

17877. **Improvements in regulators for dynamo-electric machines.** Thomas Reginald Andrews and Thomas Preece, 20, Charles-street, Bradford.

17878. **Improvements in the method of and apparatus for starting electric motors.** Thomas Reginald Andrews and Thomas Preece, 20, Charles-street, Bradford.

17895. **Improvements in apparatus for the manufacture electrolytically of tubes and other articles of circular section.** Francis Edward Elmore, 28, Southampton buildings, Chancery-lane, London.

17909. **Electric switches.** Charles Ebenezer Challis, 30, Navarino-road, Hackney, London.

17922. **Improvements in secondary batteries.** Frank King and Edward Clark, 47, Lincoln's-inn-fields, London.

17930. **Improvements in secondary batteries.** Julius Hirshfeld, William Morison, Andrew Patterson Morison, and William Wright, 165, Broadway, New York, U.S.A.

17931. **Improvements in battery compounds.** Julius Hirshfeld, William Morison, Andrew Patterson Morison, and William Wright, 165, Broadway, New York, U.S.A.

OCTOBER 8.

17973. **Improvements in electrolytic tanks.** James Charles Richardson, 23, Claremont square, London.

17974. **Improvements in plating metallic surfaces and also prepared surfaces of non-conducting substances by electro-chemical deposition.** Pascal Marino, Ashburn House, Esher, Surrey.

17982. **Improvements in brushes for electric current generating and receiving machines.** Alfred Julius Boult, 323, High Holborn, London. (Louis Boudreaux, France.)

SPECIFICATIONS PUBLISHED.

1891.

15705. **Electric signalling on railways.** Walkinson and Frem.

16076. **Coin freed telephonic system.** Wrattisch and Vergaceovica.

18162. **Electrical lamp, etc., fittings.** Gover.

19211. **Electric meters.** Teague and Moy.

19625. **Electric lighting.** Grundy.

19778. **Electric lighting apparatus.** Dawbarn.

19854. **Dynamo brushes.** Dickson and Shapcott.

19914. **Electric arc lamps.** Barton. (Jandus.)

20139. **Electric signals.** Gent and others.

1892.

11952. **Electric meters.** Jones.

13639. **Mechanical telephones.** Simpson.

14014. **Secondary batteries.** Fell. (Morrison.)

14558. **Incandescent electric lamps.** Dorman and Smith.

14738. **Electric arc lamps.** Cooper.

14822. **Incandescent electric lamps.** Lake. (McOuat.)

NOTES.

American Electric Railroads.—The number of electric railroads has increased this year from 385 to 469.

Elgin—On Tuesday, owing to an accident at the gas works, the whole town of Elgin was plunged in darkness.

Electric Cooking.—Messrs. Crompton are bringing out a new electric oven to supplement the other electric cooking appliances shown by them.

Bristol.—The Corporation of Bristol have appointed Mr. H. Faraday Proctor, of Newcastle-on-Tyne, to be clerk of the works for their electric lighting installation.

Curious Strike.—It is stated that the workmen of the Popp Compressed Air Company, of Paris, are intending to strike in order to obtain the reinstatement of M. Victor Popp.

Electric Organs.—The Hope-Jones electric action is being applied by Messrs. Norman Bros. and Beard to the following organs: Hastings, All Souls' Church; London, St. Frideswide's Church; Liverpool, Presbyterian Church, Sefton Park; Blackheath, Christ Church.

Domestic Lighting.—We have received a copy of "Domestic Electric Lighting Treated from the Consumer's Point of View," by Ed. C. de Segundo, A.M.I.C.E.; a paper-covered book of 115 pages, price 1s.; published by Alabaster, Gatehouse, and Co., 22, Paternoster-row, E.C.

Industrial Electricity.—A work has recently been published by F. Rouge, Lausanne, entitled "Couro d'Electricité Industrielle," 15 lectures given to the engineers of the Jura-Simplon Railway by A. Palaz, professor of electricity at the Lausanne University; 416 pages, with 350 illustrations.

Albert Palace.—The anonymous donor of over £10,000 to the Albert Palace Polytechnic is understood to be Mr. J. Passmore Edwards, the wealthy and philanthropic proprietor of the *Echo* and other papers. Several public buildings in Cornwall have recently been built and endowed by the same generous benefactor.

Association Francaise.—At the meeting of the French Association for the Advancement of Science at Pau a new accumulator was brought forward by Edouard Peyrusson. Drs. Gautier and Larat gave a paper on alternate currents and their therapeutic application, and Dr. Gautier another on "interstitial electrolysis."

Institute Dinner.—It has been decided by those in authority that at the dinner of the Institution of Electrical Engineers, which is to take place on the 18th of November, the speeches will be kept short, and at a comparatively early hour those present will adjourn to a smoking-room to listen to music and to talk with their friends.

Technical Index.—An index to all the articles in the English and American technical press has been compiled, to be issued monthly, price 1dol. a year, by the "Engineering Magazine" Company, New York. Any inventor who is working out a special problem can see in this index what current articles are being given on his topic.

Chicago World's Fair.—The Siemens and Halske Company of America have prepared plans for an electrically lighted theatre, in which "Columbus balls," in old-fashioned costumes with electrical effects, will be held in Chicago. A novel idea is a spiral tower, 560ft. high, which will have an electric railway running around it to the top, and a platform 200ft diameter will give plenty of space for promenade and a good view.

Resistance and Self-Induction.—A paper has been reprinted and sent to us from the *Philosophical Magazine* for September on "Equivalent Resistance, Self-Induction, and Capacity of Parallel Circuits with Harmonic Impressed E.M.F.," by Frederick Bedell and Albert C. Crehore, PhD.'s, of Cornell University. The equations give equivalent resistance and capacity of parallel circuits containing resistance and capacity only.

Old Students.—The annual dinner of the City Guilds Old Students' Association will be held on Friday, October 28th, at 7 30 p.m., at the Holborn Restaurant. It is expected that this will be the most representative gathering of Old Students that has yet taken place. Tickets, 5s. each, can be obtained of the hon. sec., Mr. E. B. Vignoles, 28, Lanhill-road, Elgin-avenue, W. Music will be given by Messrs. FitzGerald, Emerson, and Jacoby.

Chamber of Commerce.—A meeting of the Electrical Trades Section of the London Chamber of Commerce will be held on Friday, the 21st inst., at 3 p.m., at the offices, Botolph House, Eastcheap. The following points will be considered: Chicago Exhibition; County Council Overhead Wires; Arbitration; Standardising of Machinery; Uniformity of Prices; and Foreign Competition. With such an interesting agenda, the attendance should be good and the discussion lively.

Tramway Starter.—An invention which might conceivably be of use also in mechanically propelled cars, has been designed by Mr. J. F. Fide, of the Bombay Mint, for doing away with the strain on tramcar horses at starting. The invention consists of a ratchet wheel fixed to the axle of the car, worked in connection with a lever, and it is stated effects nearly 50 per cent. reduction in the strain of starting. The appliance automatically throws itself out of gear as soon as the car has gone a distance of 18in., and can be adapted to other vehicles.

Employment Register.—The London Chamber of Commerce employment register has proved very successful, we learn from the secretary's report. Anyone who wishes to engage a clerk, linguist, secretary, or traveller can obtain good men by consulting this register. A list of persons open to undertake agencies in different parts of the world is also kept. It has been suggested that the Chamber should organise a labour bureau for the kingdom, and this desirable proposal is under discussion, and suggestions will be received by the secretary.

Infancy or Manhood.—The meeting of the Londonderry Corporation last week was memorable in the history of electric lighting, as being the first recorded instance where a member of a town council—Councillor Magee, chairman of the Electric Lighting Committee—actually used the words "The electric light is not in its infancy." We have been so often told, and are even now told from time to time, of the "infancy" of the electric light, that it is worth recording that at last the definite idea of the vigorous manhood of the new illuminant is acknowledged by the men who used to carp against its introduction.

London Association of Engineers and Draughtsmen.—A paper was read by Mr. R. J. Bott, before the society, on "Electricity from the Supply Company to Consumer." Mr. Bott divided the types of central stations into three categories—slow-speed machines and very large dynamos, the continental practice, high speed machines and very high speed dynamos, the American common practice, and high-speed engines coupled direct to dynamos, the usual English practice, of which the latter was, he thought, the preferable. He described low-tension feeder and high-tension transformer systems, and was awarded a cordial vote of thanks for his interesting paper.

Cabstand Telephones.—A subscriber to the telephone system writes to the *Leeds Mercury* to make a suggestion

which would be of great service to all subscribers to the telephone, and a good source of profit to cab proprietors—that the public cabstands should be attached to the telephone; this would enable subscribers at once to call a cab from the nearest stand. There are about 16 private stands already in connection in Leeds, it appears, but not a single one of the public stands. The value of telephone connection is a matter that should at once have the attention of cab proprietors, and, indeed, it might be quite worth while to have a public call box as well at each cabstand.

Cannes.—The direction of the electric lighting station at Cannes has been taken by M. Grivolas, of Paris, whose name is well known with reference to electric appliances. The large number of visitors who pass their winters in Cannes, and are not afraid of their pockets, makes this a suitable place for a splendid installation. Up to the present there are 6,000 lamps lighted, and it is expected over 8,000 will be required this season. There are two Ferranti alternators of 120,000 watts each, and three continuous-current machines, with large batteries of accumulators. Two steam engines of 200 h.p. and one turbine of 180 h.p. supply power, and no failure of the light has occurred.

Cathedral Lighting in Vienna.—St. Stephen's, the famous cathedral of Vienna, and one of the finest and largest Gothic structures in the world, was for the first time lighted by electricity at Sunday's service. A trial of the new light was made on Saturday in the presence of Cardinal Archbishop Gruscha, and proved very successful. Twelve arc lamps are used, each of 1,000 c.p., being distributed over the church, four in each of three naves. The effect was quite dazzling, the smallest architectural and decorative details being visible. In some respects, of course, this was not wholly an advantage, the brilliancy of the light being certainly less impressive that the "dim religious light" of the former method of illumination.

Telephotography.—It has been the dream of electrical men that photographic scenes could be sent by electrical means to a distance. According to recent advices the method of doing this has been perfected, and H. E. de Ville, a Paris gentleman, is now in Chicago in the interest of a syndicate which proposes to flash accurate photographs of the World's Fair over the wires, and have them reproduced on a large scale on a canvas background in the various cities, by means of a system of telephotography. M. de Ville refers enquirers into the system to an article that appeared in the Paris *Figaro* some three years ago, commenting on the experiments of M. Henri Courtonne, a French chemist. It sounds rather chimerical.

New Books.—Messrs. Whittaker and Co. will issue next week a new work by Mr. Allsop, entitled "Practical Electric Light Fitting," a treatise on the wiring and fitting up of buildings deriving current from central station mains, and the laying down of private installations, including the latest edition of the Phœnix Fire Office rules. The work will be fully illustrated. They expect to have ready also Part 1. of Mr. Maycock's new "Elementary Manual of Electric Lighting and Power Distribution," for students preparing for the ordinary grade examination of the City and Guilds of London Institute and general readers; copiously illustrated with original diagrams, and with questions and ruled pages for notes.

Electric Sculptor's Tool—The sculptor's electric reciprocating tool, invented by Mr. W. P. Carstarphen, of Denver, is coming into practical use. It would constitute a valuable application of portable storage batteries, for it only requires two or three cells giving four to six volts and eig[illegible] amperes of current. A stonecarver can do as much with this tool in a day as four or five men with chisels and mallets. It weighs about 6lb., has reciprocating coils, switch on and off by the motion of the chisel itself, and the stroke can be regulated by a button from ¼in. to 1in., while the rapidity can be varied from 300 to 600 strokes per minute. A company is being formed at Denver to manufacture this invention, which is likely to be of great usefulness to sculptors and masons.

Electric Light Staff.—The work at the Manchester square station is divided into three watches of eight hours each on weekdays, and two watches of 12 hours on Sunday. This plan, which was originally designed by Mr. Gordon for the Paddington installation, has since been adopted in a number of other places. The weekday watches are from 7 a.m. to 3 p.m., from 3 p.m. to 11, and from 11 until 7 a.m. As there are only two watches on Sunday, the men are shifted in their watches every week, so that a man employed on the first watch one week is on the second watch the following week, and on the third the week after that. Each man works on an average 56 hours a week—first week 60, second week 60, third week 48 hours, and he gets completely off every third Sunday.

Nepaul (India).—The grand electric light installation that has been in course of execution since last year, in the new summer palace of H.H. the Maharaja Beer Shumsher, Prime Minister of Nepaul, at a cost of about a lakh of rupees, has just been brought to a successful completion. There are 250 16-c.p., and 10 300-c.p. incandescent lamps, and one 40,000-c.p. search-light in the circuit. On the first experiment in lighting being made, the search light threw out such a flash of light that the whole valley was more or less illumined. The work has been very creditably carried out, says the *Indian Engineer*, by Mr. Lester Betts, electrician to the great Silvertown firm of electrical engineers—the India Rubber, Gutta Percha, and Telegraph Works Company—whose branch house in Calcutta undertook the work of installation.

New York and Chicago Telephone.—The direct telephone line between New York and Chicago, which was tested on Tuesday, is the longest in use up to the present. A wire giving direct talking communication with Buffalo has been used for some time, but that city is only about half the distance of Chicago from New York. The new line is 950 miles, less a furlong, in length. It runs through Harrisburg, Altona, Pittsburg, Youngstown, Toledo (Ohio), and Southbend (Indiana). The wire weighs 435lb. to the mile, and is ⅛in. in diameter. If the line between New York and Chicago is found profitable, it will be extended to San Francisco. Prof. Bell is very sanguine as to the financial result of the enterprise. He declared on the occasion of this test that in his opinion the whole civilised world will be eventually connected by telephone.

Lecture at Manchester.—Prof. Silvanus Thompson delivered a highly interesting technical lecture on "Magnetic and Electric Fields," in the Manchester Town Hall on Monday, by arrangement with the Technical Instruction Committee. The large hall was crowded. The Mayor of Manchester presided, and in introducing the lecturer spoke of the high position electricity now occupied. They, in Manchester, had spent a large sum of money in fitting up a school for the study of electricity. Electricity had been applied to the telephone, the telegraph, and the light, and they were all glad to receive information as to the development of the science. Prof. Thompson, in the course of his lecture, dealt largely with the space surrounding magnetised bodies, and illustrated his remarks by many interesting experiments. The lecture was followed with deep interest, and at its close Prof. Thompson was accorded a hearty vote of thanks.

Electric Light Current in a Clock.—In Berlin the other day, recounts the *Daily News*, a workman was boring a hole in a wooden wall in order to put in a screw, when he received a strong shock, and, ignorant of the cause, he left the gimlet in the hole and fled. At the same time the electric clock of the "Urania" opposite the house suddenly stopped, and the electricians who manage the clock for a long time could not imagine what was the matter. The workman while boring had pierced the thin wooden wall and the lead covering of the electric cable which regulates the Urania clock, and at the same time slightly touched an electric light cable with his gimlet. In this way a communication was established between the two cables, and the strong current from the light cable was led into the clock cable, when proving far too strong for the clock, it stopped the works.

The Telephone in France.—The Administration of Posts and Telegraphs, which a short time ago took over the telephones in France, has just published a very interesting report, according to which there are now 112 towns in France provided with telephone communication. These towns represent a population of over six millions, this being nearly a sixth of the total population of France. When the State took over the telephones, there were only 11,440 subscribers, whereas there are now 18,191, rather more than half of whom are in Paris. But while this gives a proportion of only one subscriber to 253 inhabitants, there are several other towns in which the proportion of subscribers is much higher, being 1 in 215 at Mentone and 1 in 120 at Cannes, while in several of the large industrial towns of the North there are also relatively more subscribers than in Paris. The total received from subscribers for the past year was £210,960, of which nearly two thirds was derived from Paris.

Giraud Thermopile.—Each of the elements of the Giraud thermopile is formed of an alloy, whose exact composition is made to vary with the size of the element, so that the E.M.F. may remain constant without the internal resistance increasing. The following are the three types of electrodes which are found to be the most advantageous: A (small type), length 70 mm., width 20 mm., height 20 mm. ($2\frac{3}{4} \times \frac{3}{4} \times \frac{3}{4}$in.); composition in parts by weight: antimony 1,450, zinc 900, cadmium 50, pure copper 80, tin 40, silicium 3. B (ordinary type), dimensions 70 × 20 × 30 mm.; composition: antimony 440, zinc 780, cadmium 60, pure copper 30, tin 15, silicium 2. C (large type), 70 × 30 × 50 mm.; composition: antimony 1,830, zinc 960, cadmium 65, silicium 2. The other electrodes are composed preferably of plates of tinned iron or of pure nickel; but these electrodes, it is stated, may also be of iron, plated on the surface with either iridium, platinum, or nickel, or may be of ferro-aluminium. The two electrodes are soldered together at the moment of the fusion of the alloy.

House of Lords.—Hitherto the House of Lords has lagged behind the House of Commons in the matter of electric lighting. Now, however, the hereditary legislators will be better provided for in this respect than the members of the Representative Chamber. Ten electroliers, each containing 36 16-c.p. lamps have been made, and when these are in position it is believed that the House of Lords will be one of the best lighted buildings in London. The candelabra on each side of the Throne will be allowed to remain, but the old gas pendants are being taken down, and electricity will be the illuminant for all practical purposes. The apparent backwardness of the House of Commons in this connection is not due to any want of enterprise on the part of the Office of Works. The central hall, the members' lobby, the dining-room, smoking-rooms, library, and reading-room, and most of the corridors and private apartments have been lighted by electricity for some time, as well as the reporters' gallery. But in the House of Commons itself the system of gas illumination and ventilation are so interdependent that the suppression of the gas would seriously impair the efficiency of the ventilation.

Edison Patent.—The trial in the great American incandescent lamp case, which has extended from court to court for over 12 years, has now been suddenly decided fully in favour of Edison, who thus obtains control over the lamp manufacture, with a right of exacting royalties for past manufactures. It is too early to learn how the General Electric Company (which owns the Edison patent) is going to act, but the back royalties are stated by their attorneys to amount to over 15 million dollars. There are about 20 incandescent lamp makers in the States besides the Edison factory, though the latter produces 40 per cent. of the whole. The questions now being asked are whether licenses will be granted or whether the General Electric factories will be increased to cope with the monopolised demand. The Thomson-Houston clique have benefited the most by this decision, for they have by their amalgamation with the Edison Company avoided the necessity of fighting, and now possess a more valuable property than was bargained for. Possibly if the decision had come a year ago, no amalgamation would have taken place. It is not thought that drastic measures will be taken, though no declaration of policy is yet announced.

Another Swindle. — We have heard of "bottled lightning," but the Hungarians have got hold of the bottler. The Pesth correspondent of the *Montags-Revue* says that "a professor" from America has been travelling through the provinces to interest the peasant farmers in his new invention, which he calls the "lightning trap," and to get orders for his electrical "traps." The professor erects tall poles, which attract the lightning, and by means of a system of wires he collects the electric sparks in small caskets, the walls of which are so constructed that the bottled lightning is isolated and preserved in a fresh and lively condition. It can be carried about from place to place, and so utilised for agricultural purposes that any farmer can have what he so often wants, a shower of rain upon some particular field, while all the fields around continue dry. "The professor" caught and imprisoned no fewer than 14 flashes of lightning during the storms of August. Unfortunately, the Hungarian police authorities are less accessible to new scientific ideas than the country peasants. The American professor has been treated by them as he proposed to treat the lightning—"caught and imprisoned for the profit of the agricultural population." He is now in jail as a swindler.

Belfast.—The special correspondent of the *Belfast Evening Telegraph*, who has been writing a careful set of articles on the various London electric light stations, has interviewed Mr. J. E. H. Gordon. Mr. Gordon, as is known, has done a great deal of work in Ireland already. He has a special desire, says the correspondent, to spread the light in darkest Ireland, and has suggested that in Belfast the Corporation ought to drive an electric light station by means of gas engines. It would be expensive to use the purified gas, but the "rubbishy gas" which is not at present sent out to customers might be used. As the Corporation own the gas works, it would be to their advantage to proceed on this basis. He favours the direct-current system for this town, and considers the cost should be about £30,000 for an installation. The commissioner of the *Belfast Evening Telegraph*, in the issue of October 17, gives a long and full description of the Kensington and Knightsbridge central stations, erected by Messrs.

Crompton and Co. There will be in all 22 articles, we are told, appearing day by day, on electric light in London and the provinces, and we should fancy the readers of this paper will be amongst the best informed on the present status of electrical engineering of any, outside technical readers, at this present day.

Electro-Harmonic Society.— The next smoking concert of the Electro-Harmonic Society will be held on Friday, October 28, at the St. James's Hall Restaurant (Banquet-room), Regent street, W., at 8 o'clock. Artistes: Master Frank Barnes, Mr. Walter Coward, Mr. Harper Kearton, Mr. R. E. Miles; violin, Mr. T. E. Gatehouse; piano, Mr. Alfred E. Izard; humorous selections, Mr. Robert Ganthony, musical directors, Mr. T. E. Gatehouse and Mr. Alfred E. Izard. Programme: Part I.—Glee, "Hark! hark! the lark" (Cooke), Master Frank Barnes and Messrs. H. Kearton, W. Coward, and R. E. Miles; Spanish scena, "The Night Watch" (Pinsuti), Mr. R. E. Miles; pianoforte solo, "Scherzo, Op. 20" (Chopin), Mr. Alfred E. Izard; song, "Two Messengers of Love" (Forrester) Master Frank Barnes; violin solo, (*a*) "Romance" (Svensden) (*b*) "Pizzicati" (Delibes), transcribed by Marsick, Mr. T. E. Gatehouse, scena, "Adelaida" (Beethoven) Mr. Harper Kearton; burlesque lecture, "The Funnygraph," Mr. Robert Ganthony. Part II. Part song, "In this Hour" (Pinsuti); ballad, "Sometimes" (S. Forbes), Mr. R. E. Miles; violin solo, "Rapsodie Irlandaise" (Hauser), Mr. T. E. Gatehouse; duet, "Excelsior" (Balfe), Mr. Harper Kearton and Mr. R. E. Miles; song, "Sweet Nightingale" (Boscovitch), Master Frank Barnes; song, "Zanita" (H. Trotere), Mr. Harper Kearton; musical sketch, "Recollections," Mr. Robert Ganthony.

Grounded Low-Pressure Wires.—The most recent advices from America show that there is a conflict between the electric light companies and the Board of Underwriters. It seems that the Board of Underwriters notify that on and after October 1st no more grounded wires would be approved of by the Board. It is said that all the companies have complied with this order except the Edison Company. Many of the firms who are being supplied by Edison incandescent circuits are declaiming against what they term the arbitrary proceedings of the Board of Underwriters. They are not quite sure whether their policies will hold good or not, and say that if the Edison system was not dangerous before Oct. 1, why is it held to be dangerous now? There is a good deal in this contention, but it must be recollected that fire insurance companies have to take care of themselves, and if they find the risks increase they are bound to show some signs of this and to make new rules. We, however, are strongly of opinion that in this case the Board of Underwriters are in a false position. Still, our readers are more concerned with English practice than with American practice, and we think it is admitted, even on that side of the Atlantic, that we have paid greater attention to everything that concerns safety, and are more careful in carrying out our work with due precaution, than they are on the other side.

The Central Institution.—Of the 109 candidates who recently entered for the matriculation examination at the Central Institution, Exhibition road, 73 passed, and six did sufficiently well to be allowed to join the college as unmatriculated regular students. In addition to these 79 thus admitted, each to attend courses in all the four departments of mathematics and mechanics, engineering, physics, and chemistry, and those who, having been admitted in previous years, have not yet completed their course, some 40 special students have joined the advanced courses in one or more of these departments, thus bringing the total number of students at the Central Institution up to the maximum for which it was intended. On the result of this entrance examination the Clothworkers' Scholarship of £60 a year, with free education for two years, and renewable for a third, was gained by W. G. Bennett, from the Bancroft School; the Mitchell Scholarship of £30 a year for two years, with free education, by E. W. Hummel, from the Finsbury Technical College, the Clothworkers Technical Scholarship of £25 a year for two years at the Finsbury College, and £30 a year for three years at the Central Institution, both with free education, by W. C. Maers; and four Institute's Scholarships of sufficient value to cover the fees for three years, by M. J. P. O'Gorman, from the Royal University, Dublin; W. T. Gidden, Bancroft School; and A. D. Constable and W. A. Davis, both from St. Dunstan's College, Catford. At the end of the last session the John Samuel Scholarship of £30 and free education for a third year's student, was awarded to H. C. Leake; and the Siemens Medal to C. V. Drysdale.

Communication with Lightships.—Mr. Hobbs, of Ramsgate, the promoter of the scheme for telegraphic communication between lightships and the shore, writing to a Dover correspondent, states that he is officially informed that the report of the Royal Commission, which will be presented after the meeting on the 19th inst. will recommend that the Goodwin lightships be telegraphically and telephonically connected with the shore, the East Goodwin lightship being connected with Dover. The work will be carried out on Lucas's patent system. A system of telegraphic communication on shore is also being rapidly pushed forward on the south-east coast. At Ramsgate and Margate some of the wires are already laid in connection with coastguard stations, and arrangements are being made to connect various points with the North Foreland on the one side and Deal on the other, while similar arrangements are being made at Hythe and New Romney, so that the dangerous coast line between the North Foreland and Dungeness will soon be provided with ready means of inter communication. It is understood that the system will, as soon as possible, be extended round the entire coast. The Royal Commission upon electrical communication between lighthouses, lightships, and the shore met again on Wednesday, the Earl of Mount Edgcumbe presiding. All the members were present except Mr. Munro Ferguson. Evidence was received from the masters of the following lightships: North Lasbor, near Cromer; Woold, Cross Sand, Ship Wash, Kentish Knock, North and East Goodwins, and from Mr. Williams, district officer of coastguards at Aldborough. The Commissioners are meeting again to receive further evidence, and it is their intention to issue shortly an interim report.

Electric Railways.—To reside some 60 to 100 miles away from one's place of business would seem to be an easy probability for the future citizen, if the electric high speed railways do all they are expected to accomplish. Instead of a town being a centralised aggregation of houses, we may return to the old long, straggling high-street of a century ago, but on an extended scale. Boulevards are to stretch away from the so-called towns, lined with trees and secluded houses. They will be lighted by electricity, and fitted with motors and heaters. Between the lines of houses will stretch a long straight road of double or triple lines of railway, the centre rails for high-speed express trains, the outer for stopping trains, while outside will be a carriage road fitted with electric trams. The resident will take his tram, run to the nearest station, go by train to the express stopping place, and from there be whisked to his destination, the whole distance up to 60 or 100 miles being done within the hour. Our towns will approximate to the

geometrical notion of a line—length without breadth. Every man can live in his own domain with plenty of fresh air. The entire line will be enclosed, the carriage crossings going over and the railway lines under. The New York *Electrical Engineer* gives a bird's-eye view of such a scheme, which is to be carried out in practice at once for the St. Louis and Chicago Railway. The order has been placed for the electrical equipment of the first car to the specification of Dr. Wellington Adams, the builders guaranteeing a pair of motors to develop the required power to run the cars at the specified speed of 100 miles an hour. The best electrical engineers and the best established financial houses in America and Europe are understood to have promised their assistance, with a view of completing within the specified time this bold enterprise, which, when carried out, cannot but give an immense impetus to electric traction enterprises throughout the world.

The Telephone System in Switzerland.—The Geneva correspondent of the *Economiste Français* states that the increase in the number of telephone lines since the new tariff came into operation, about two years ago, has been very remarkable. Previous to that, there were 61 telephone lines, with 6,944 speaking stations and a revenue of about £44,000, the annual subscription being £6, with no limit to the number of conversations. The new tariff lowered the subscription to £3. 4s. (80f.), and the result is that at the beginning of the present year there were 101 telephone lines, with 12,595 speaking stations, this being equivalent to an increase of 81 per cent. The length of lines is 3,225 miles, while there are 13,340 miles of wires, the principal lines being those of Geneva (2,176 stations), Zurich (1,712), Basle (1,522), Lausanne (806), Berne (753), and St. Gall (596). The total number of messages between residents in the same town was 6¾ millions, while there were 687,000 conversations exchanged between different places. The new law stipulates that each subscriber shall be entitled to only 800 conversations in the course of the year, and pay ½d. for each one over that number, but over 78 per cent. of the subscribers kept within the prescribed limits. Although the total receipts amounted to £65,400, the expenses incurred in putting down new lines and increasing the staff were so great that the net receipts were about 4 per cent. less than in the year previous to the passing of the new law, but for all that the profit derived by the State is so large that these expenses will soon be paid off, and a surplus will soon be available. The development of telephone communication has, says the *Times*, as might be expected, checked the increase in telegraphic communication, the number of telegrams showing only a fractional increase upon those of the previous year, while it is anticipated that there will this year be an actual decrease.

Electric Spark Photography.—Mr. C. V. Boys, F.R.S., assistant professor at the Royal College of Science, delivered the second Gilchrist lecture in connection with the university extension at Reading last week, on the subject of "Electric Spark Photography," the Mayor being in the chair. The lecturer first explained the speed of the electric spark. He then showed photographs taken by Lord Rayleigh, by means of the electric spark, of various soap bubbles in the act of bursting, and explained the process, the photographs showing that various bubbles did not break at exactly the same rate (about 30 miles a minute). Another photograph showed the issue of liquid from a very small pipe, which to the naked eye appeared a perfect stream, but which on an electric photograph being taken, was resolved into a beautiful and regular series of drops; and in this connection the lecturer remarked that the science of liquid volumes and of the forces which had to do with the surface of liquids was one of the most interesting branches of physical science. As they probably knew, playing or singing to a fountain suddenly changed its appearance from drops into one, two, or three apparently separate clear streams of liquid, but a photograph shown, taken as a tuning-fork was struck, demonstrated that the water was disposed, in drops, in a beautifully regular fashion. Mr. Boys went on to deal with photographs of bullets in motion, showing first a picture of a rifle bullet going at the rate of 2,000ft. a second, and this, being taken by the ordinary electric spark, was considerably blurred. If it were wished to investigate what was really happening when a rifle bullet was passing through the air, it was necessary to illuminate with something even more instantaneous than the electric spark. For the purpose of investigating the duration of the electric spark, he had caused to be made a mirror of steel about the size of a shilling, so mounted as to revolve with ease, without getting hot, at the enormous speed of about 1,000 turns per second, and the end of the beam of light given off from the mirror passed across the screen at a rate he hardly liked to mention; but practically the photographs he was about to show were taken by that apparatus (which was not his invention, but was devised by Germans) in about one ten-millionth part of a second. Special attention was directed to the varying formation of the air waves created by the progress of bullets from a pistol, a Martini-Henri, and a Winchester rifle, respectively, which were compared with the vibrations in the air caused by sound. These experiments, which were all fixed by photography, were clearly shown on the screen, and excited much interest. Some 50 years ago Mr. Russell Scott prepared a series of most important diagrams relating to water waves, and by pictures the lecturer showed that air waves precisely corresponded. Photographs were next shown exhibiting the appearance of charges of shot from cylinder and choke bore barrels of a gun; and, in conclusion, half-a-dozen pictures taken as a bullet was passing through a sheet of plate glass, showing in the most marvellous manner the whole phenomenon from beginning to end, the pictures and their explanation being loudly applauded. Mr. Boys said they might ask why he had chosen such an extraordinary subject to lecture on as the photographing of bullets. He knew nothing of bullets himself—and probably they did not—and he did not care much for photography. All that was of interest in the present subject, from his point of view, was this—that there was a certain difficult thing which was of interest to a certain class of people, and it was interesting to try by some means or other to solve that problem. By the use of means which were by no means complicated, but which were, as he had shown, almost ridiculous in their simplicity, a problem which some would say was altogether beyond the reach of experiment had been solved with absolute ease and certainty. One could find out by scientific method things which would be said at first to be absolutely impossible of discovery; and when one began to find out those secrets one was always rewarded by coming across curious and unexpected phenomena, which formed the bases of scientific discovery. The knowledge that very often their preconceived ideas would get knocked on the head by coming across the unexpected, formed the fascination and delight of the scientific experimentalist; and therefore he had chosen that subject as a simple and fairly intelligible example of the experimental art. The lecture was received with the greatest interest.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.Sc.

IX.

(Continued from page 2..9.)

RESISTANCE *continued.*

Dial Forms of Wheatstone's Bridge.—There is another class of Wheatstone's Bridge, similar in construction to the Post Office form, but very different in the arrangement and value of the coils in the known variable resistance. Instruments of this class are termed dial forms or rectangular forms of Wheatstone's Bridge, according as the resistances are arranged in circles, as in Figs. 18, 19, and 20, or in pairs of parallel lines, as in Figs. 21 and 22. In both of these forms the known variable resistance is arranged in sets of nine coils all of the same value, the sets themselves increasing in powers of ten. Thus, in the different examples shown in Figs. 18, 19, 21, and 22, the coils comprising the known variable resistance are as follows:

nine coils of 1 ohm each,
,, ,, 10 ohms ,,
,, ,, 100 ,, ,,
,, ,, 1,000 ,, ,,

and in the example of a dial instrument shown in Fig. 20, there are in addition to these

nine coils of $\frac{1}{10}$ ohm each,
and ,, ,, 10,000 ohms ,,

The manner in which the coils are arranged, and one method of connecting up the unknown resistance R, the galvanometer, the battery, and their keys, is illustrated in Fig. 19, which is a diagrammatic representation of the instrument shown in Fig. 18. From Fig. 19 it will be seen that each dial consists of 10 massive metallic junction pieces numbered consecutively from 0 up to 9, and arranged in circular form round a metal centre-piece which is connected by a thick underboard copper strip or wire to the zero junction piece of the next dial.

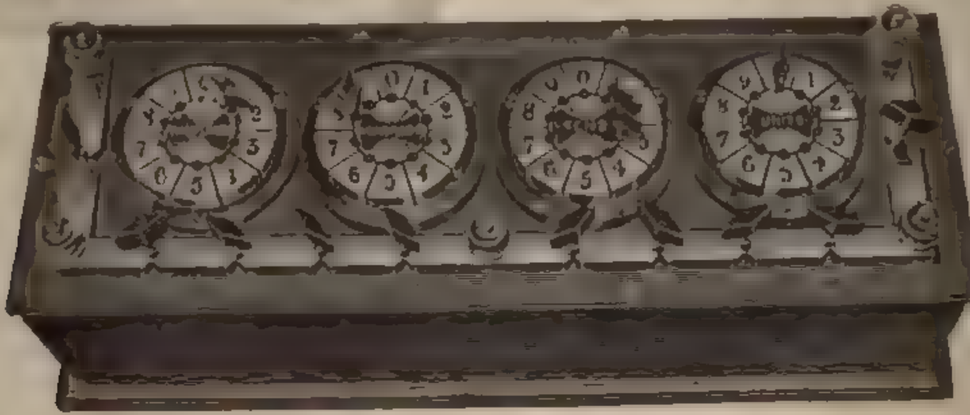

FIG. 18.—Wheatstone's Bridge, Dial Pattern.

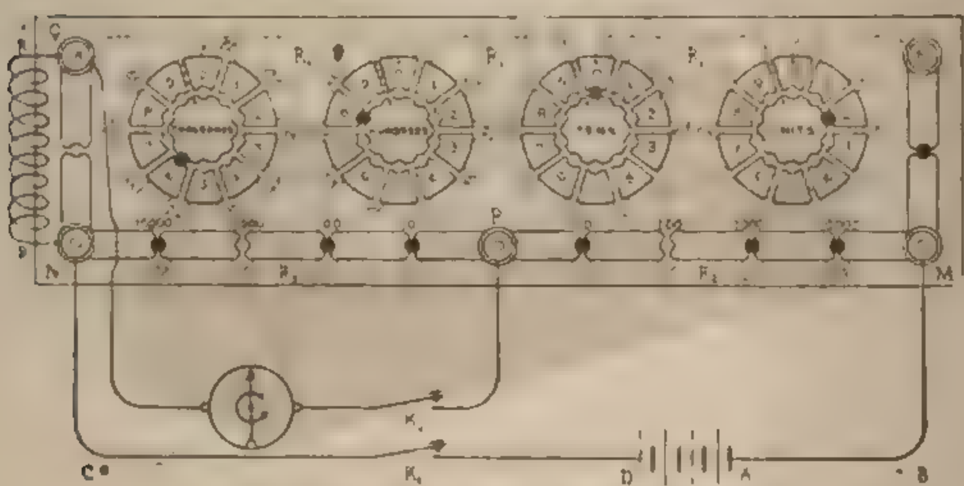

FIG. 19.—Diagram of Wheatstone's Bridge, Dial Pattern.

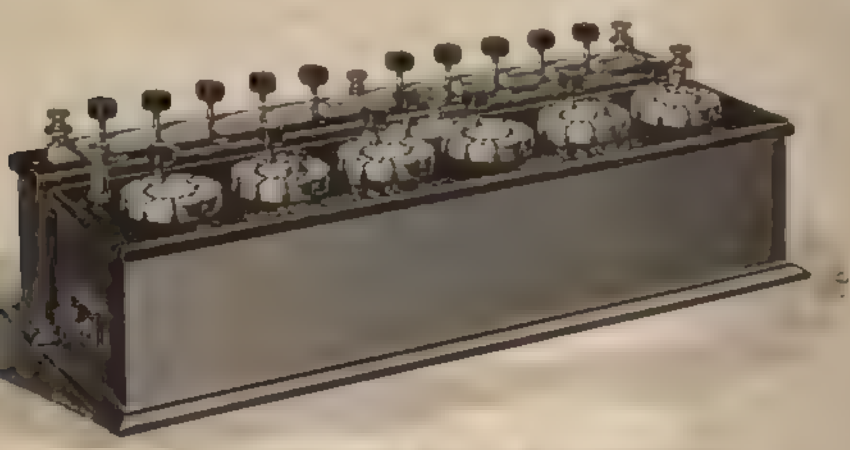

FIG. 20.—Wheatstone's Bridge, Dial Pattern, with Detachable Ratios.

The two ratios, R_2 and R_3, each consisting in this example of four coils of 10, 100, 1,000 and 10,000 Ohms, are ranged along one side of the instrument, and from their ends M and N project two arms as shown, each provided with an infinity plug for breaking the circuit. The zero junction piece of the units dial and the central piece of the thousands dial are connected to the extremities of these arms by thick underboard copper strips or wires, as indicated by the dotted lines in Fig. 19.

The advantages of this method of grouping the coils, over the earlier modes will be at once evident. Only one plug is necessary for each dial, and the readings are direct, the number of coils through which the current must pass in each dial being indicated by the number on the junction piece against which the plug is inserted. Thus, the reading of the dials in the instrument shown in Fig 18 is 2,850 Ohms, while that in Fig. 19 is 6,802 Ohms. With the arrangement represented in Fig. 19, if the galvanometer shows no deflection when the keys are closed, then the value of the unknown resistance R will be found as follows:

$$R = R_1 \times \frac{R_2}{R_3},$$

$$= 6{,}802 \times \frac{1{,}000}{100},$$

$$= 68{,}020 \text{ ohms.}$$

Another example of the dial form of Wheatstone's Bridge is shown in Fig. 20, which illustrates an instrument in which the ratios R_2 and R_3, and the known variable resistance R_1 are contained in separate boxes, connection being made, when desired, by stout copper wires or strips as shown in the illustration. In this case, each of the two ratios consist of five coils of 1, 10, 100, 1,000, and 10,000 Ohms; and the known variable resistance comprises six dials ranging from tenths of an Ohm to ten thousands of Ohms, the maximum reading being 99,999·9 Ohms, or practically 100,000 Ohms. There is an infinity plug situated about the centre of the six dials, and as both of the brass pieces for this plug are provided with screw terminals as shown in the illustration, this plug can also be used for dividing the coils into two separate groups of three dials each.

This instrument, as well as the one illustrated in Fig. 22, is provided with what is known as a Hockin and Taylor's thermo-coil, of which the clamp terminals are shown in the illustrations, projecting from the end of the known-variable-resistance box. This device consists of a coil of insulated copper wire wound round about the coils of the known variable resistance so that it may readily acquire the same temperature, and it is so adjusted that its resistance is exactly 100 Ohms for the temperature at which the coils in the box are right (17·0° C., in the case of the instrument shown in Fig. 20). Then as this thermo-coil is of pure copper, its resistance when the temperature changes will vary differently from that of the other coils, so that if a measurement of this resistance be made, using the bridge in the ordinary way, the correction for temperature can be got from the result obtained, by means of a table of constants. The instrument is also provided with holes for the insertion of thermometers to ascertain the temperature of the coils during a measurement. The exact temperature for which the coils have been adjusted is usually marked on the instrument, so that a correction for temperature may be readily made when desired.

FIG. 21.—Wheatstone's Bridge, Rectangular Pattern.

Figs. 21 and 22 are two examples of the rectangular pattern of Wheatstone's Bridge, an arrangement due to Dr. Muirhead. This is simply a variation of the dial pattern of bridge; the junction-pieces of the coils being disposed five on either side of a long brass block, instead of the whole ten being arranged in a circle. The internal arrangements and connections are the same for instruments of both patterns. Besides being a neater and more compact class of instrument than the dial pattern, the rectangular pattern also affords much greater facilities for cleaning the contacts and spaces between the junction pieces. In the example shown in Fig. 21, the known variable resistance and the ratios are all contained in one box, whilst in the case of Fig 20 the ratios are detachable as in the six-dial instrument, Fig 20, and a Hockin and Taylor's 100-Ohm pure copper thermo-coil is also added.

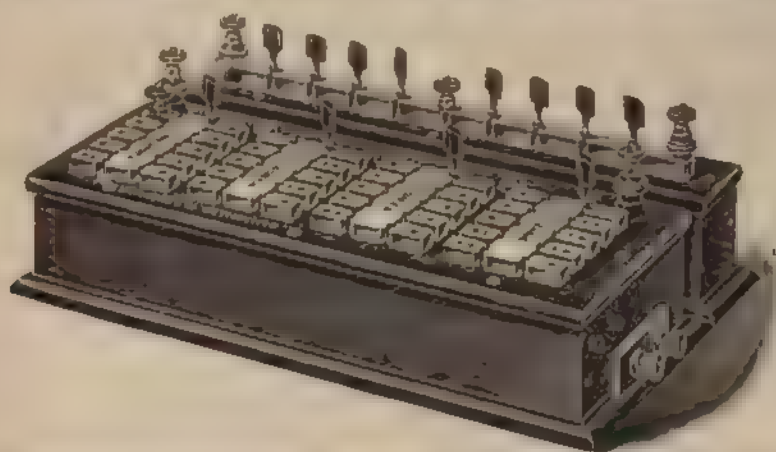

FIG. 22.—Wheatstone's Bridge, Rectangular Pattern, with Detachable Ratios.

Figs. 18 and 20 are examples of dial instruments, the former made at Silvertown Works and the latter by Messrs. Nalder Bros.; and Figs. 21 and 22 illustrate two instruments of Dr. Muirhead's rectangular pattern, the former made by Messrs. Nalder Bros., and the latter at Dr. Muirhead's works.

(To be continued.)

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

III.—WORK AND HORSE-POWER.

(Continued from page 351.)

Since the cylinder encloses the piston, the diameter of it (internally) is that of the piston.

$$\text{Area} = \frac{\pi d^2}{4}, \text{ where } d = \text{diameter,}$$

$$\text{and } \pi = 3{\cdot}1416.$$

$$\therefore \text{Area} = \frac{3{\cdot}1416 \times 81}{4} = 63{\cdot}61 \text{ square inches.}$$

Let the length of the stroke be 11in., then for the forward and backward stroke the total length will be 11 × 2 = 22in. = 1·83ft.; speed is 200 revolutions per minute, pressure is 80lb. per square inch. Thus we have

$$P = 80,\ L = 1{\cdot}83,\ A = 63{\cdot}61,\ N = 200,$$

or,
$$\frac{80 \times 1{\cdot}83 \times 63{\cdot}61 \times 200}{33{,}000} = \text{I.H.P.} = 56{\cdot}4.$$

Hence the engine will yield 56·4 I.H.P.

When the engine is compounded the steam is admitted into the small high pressure cylinder first, and the exhaust steam, which now has a very much lower pressure, say one sixth of the initial, then goes into the low pressure, or large cylinder, so that two calculations must be made and added together—one for the work done in the high-pressure cylinder, and the other for the work done in the low-pressure cylinder.

Example.—In a compound engine the diameters of the high and low pressure cylinders are respectively 10in. and 25in. Steam is admitted to the high at 100lb. pressure per square inch, and to the low at 16lb. pressure per square inch. Speed is 160 revolutions per minute, and length of stroke is 14in. Find the indicated horse-power.

The power developed in the high-pressure cylinder will be calculated first.

$$\text{Area of piston} = \frac{3{\cdot}1416 \times 100}{4} = 78{\cdot}54 \text{ square inches.}$$

$$P = 100,\ L = 2\text{ft. }4\text{in.},\ A = 78{\cdot}54,\ N = 160;$$

therefore

$$\frac{100 \times 28 \times 78{\cdot}54 \times 160}{33{,}000 \times 12} = 88{\cdot}85 \text{ I.H.P.}$$

For the low-pressure cylinder we have

$$\text{Area of piston} = \frac{3{\cdot}1416 \times 625}{4} = 490{\cdot}87 \text{ square inches.}$$

therefore

$$\frac{16 \times 28 \times 490{\cdot}87 \times 160}{33{,}000 \times 12} = 88{\cdot}85 \text{ I.H.P.}$$

The power in each cylinder is thus the same, which it must be; so that adding the two together gives the total power of the engine, or

$$88{\cdot}85 + 88{\cdot}85 = 177{\cdot}7 \text{ I.H.P.}$$

For triple-expansion engines, where three cylinders are used, the same process may be adopted.

Mechanical Equivalent of Heat.—Heat is a form of energy, and no work can be done without the production of heat. A revolving wheel contains kinetic or stored up energy, and if suddenly stopped by applying a brake, heat is at once produced, due to the tremendous friction that exists. It was of the utmost importance to know the relation that exists between the unit of heat and the unit of mechanical energy. This want was supplied by Joule, who conducted most elaborate experiments for six years in order to obtain accurate results. The chief method used by Joule was concerning the friction of fluids, and he obtained his data in the following way. A number of paddles were delicately suspended in a vessel of water, a length of string was wound round the spindle of the paddles, passed over a pulley, and then attached to a weight. Upon allowing this weight to fall, rapid motion was given to the paddles, and the great agitation of the water raised its temperature. The mechanical power was obtained by multiplying the known weight by the distance it fell, and the equivalent amount of heat created was measured by the rise of temperature of the known mass of water.

These experiments established without doubt the following law connecting heat and work: *The amount of energy produced as heat is an exact measure of or is equal to the amount of energy expended mechanically.*

Joule found that the work expended by allowing a mass of 424 grammes to fall by gravity a distance of one metre would produce sufficient heat to raise the temperature of one gramme of water through one degree centigrade, say, from 9deg. C. to 10deg. C.). This amount of heat is fixed upon as the unit of heat, and is called a Calorie. Since one gramme falling one centimetre = 981 ergs of work, therefore 424 grammes falling one metre = 981 × 424 × 10², or 41,594,400 ergs, so that one Calorie of heat may be taken to be the equivalent of 42,000,000 ergs of work done. It was shown that one watt, the practical unit of power, was equal to 10,000,000 ergs of work done per second; therefore power, or rate of doing work, can be expressed in heat units, and one calorie per second $= \frac{42{,}000{,}000}{10{,}000{,}000} = 4{\cdot}2$ watts,

or, 1 Watt = ·24 Calorie per second.

In electrical work this last formula is a very important one, for by its use, as will be seen later on, it enables the electrician to calculate the extent to which electric mains and branch wires, and also the coils of dynamos, motors, etc., are heated, when a given amount of watts of electrical power is passing through them. It is a formula that should be constantly in the mind, because the production of electricity and its distribution, whether in the form of Light or Power, is invariably accompanied by Heat. Electricity, Heat and Light, all three, are closely identical in their phenomena. From electricity, heat and light are produced; from heat, electricity and light are produced; from light, electricity and heat are produced. Magnetism also exhibits phenomena that lead us to identify it to some degree with the above three, because from magnetism electricity can be produced, and also heat. As an example of this latter statement, take the case of a bar of iron, which will become rapidly heated by magnetising it by means of an alternating current of electricity. With respect to the relations between magnetism and light, we have Maxwell's "Electromagnetic Theory of Light." This theory arose from the belief of electricity and magnetism being produced by motion of the ether (the ether being the name given to that which is supposed to pervade all bodies and all spaces), the same with regard to the propagation of light rays. An extraordinary fact is that the velocities of propagation of electromagnetic induction and of light are so close to each other as to be almost identical, the velocity of electromagnetic induction being 2·9857 × 10^{10} centimetres per second, and the velocity of light being 2·9992 × 10^{10} centimetres per second. A practical result of this identity is that whenever any disturbances of the sun's surface take place, magnetic disturbances immediately take place on the earth's surface, and affect the working of telegraphic apparatus.

It is useful to know the mechanical equivalent of heat when expressed in English units. The English unit of heat is that amount of heat which will raise 1lb. (pound) of water from 60deg. F. to 61deg. F., or 1deg. F., and the mechanical energy required to produce one unit of heat is the work done by a weight of 1lb. falling by gravity through a distance of 772·55ft., or, in other words, 772·55 foot pounds.

Hence 772·55 foot pounds = one unit of heat. This amount of mechanical energy is known as "Joule's equivalent," or by the letter "J."

The following tabulation gives values of Force, Work and Power expressed in English and French Units of Weight and Length.

TABULATION 9.

FORCE.

1 Milligramme weight represents (nearly)	..		1 dyne.
1 Gramme	,,	,,	981 dynes.
1 Pound	,,	,,	444,000 ,,

WORK.

1 Milligramme centimetre does work = (nearly)			1 erg.
1 Gramme centimetre	,,	,, =	981 ergs.
1 Foot pound	,,	,, =	13,562,850 ,,

POWER.

10^7 Ergs per second	=		1 watt.
1 Kilogramme metre per second	=	(nearly)	10 watts.
1 Foot pound ,, ,,	=		1·35 ,,
75 Kilogramme-metres ,, ,,	=	French H.P.	736 ,,
550 Foot pounds ,, ,,	=	English H.P.	746 ,,

Running Cost of Steam Engines.—Granting 4lb. of coal to the brake horse power per hour, with coal at 20s. per ton the cost of 1 b.h.p. per hour works out to ·43 or ½ penny; at 15s. per ton, to ⅓ penny; and at 12s. per ton, to ¼ penny. This is for coal alone, which varies in price according to the

locality. Other expenses, as oil, wages, water, etc., can be taken as fairly constant in price. It is very difficult to predict the annual cost of motive power; there are so many varying items which depend on local circumstances. An approximate idea can be given, however, which may be found useful. There are also great differences existing in the working expenses of engines of various sizes which are altogether out of proportion, and another great controlling feature is the number of hours per annum run; here, again, the expenses are out of proportion. A third very important point relates to the load an engine is working at; the more an engine works towards its full load the less is its proportional cost. An example will now be given of the probable annual running cost of a steam plant giving 40 b.h.p., working at full load, and running 10 hours per day, or about 3,000 hours per annum. The total cost can be divided into two equal parts, one of which will represent depreciation, interest, repairs, and wages. This half may be regarded as a fixed amount, independent of what the running hours may be. It may be argued that only wages and interest should be held as of fixed value, since the wear and tear will vary the depreciation and repairs. Strictly speaking, this is correct, but, to simplify matters, it is assumed that they remain constant. The other half of the total cost is put down to coal, oil, waste, water, and sundries—the cost of an engine and boiler, including a fair estimation for the expenses of properly fixing same, being taken at £15 per Brake Horse-Power, or £600 for 40 b.h.p.

TABLE I.

A.—INVARIABLE COSTS.

	B.H.P. per annum.	B.H.P. per hour.
Interest on outlay, £600 at 4 %	£0 12 0	·048 penny.
Depreciation „ „ 7½ %	1 3 0	·092 „
Repairs „ „ 5 %	0 15 0	·060 „
Wages of driver, £100 per annum	2 10 0	·200 „
Total	£5 0 0	·400 penny.

B.—VARIABLE COSTS.

4lb. of coal per hour for 3,000 hours, using coal at 15s. per ton	£4 0 0	·32 penny.
Water, oil, waste, and sundries	1 0 0	·08 „
Total	£5 0 0	·40 penny.

So that total cost per Brake Horse-Power per annum = £10.
and „ „ „ „ hour = ·8 penny

If the above plant be used for working the electric light, the running hours will be very much shorter. Take an average time, say from dusk until 10 p.m., this will be about 1,500 hours throughout the year, including Sundays. This is one-half of the preceding case, but the cost will not be one-half, because part of the total cost remains constant, and this amount is £5 per brake horse-power per annum. The other part of the cost will now be in proportion to the hours run, so we have $\frac{5 \times 1,500}{3,000} = 2\frac{1}{2}$. Thus the total cost for 1,500 hours = £7. 10s. per brake horse-power per annum, or 1·2 pennies per brake horse-power hour. If the hours were shorter the proportional cost would be greater, and if longer it would be less. When the cost per hour works out very small, then the plant is said to possess great earning capacity, and this applies to all machinery, whether steam engines, gas engines, dynamos, or what not. This point is a very serious question in central electric light stations, for the expensive plant has to be idle all day, and is only earning money on an average of half a dozen or so hours per day out of the 24.

We will now investigate the running cost of small sized steam engines. The outlay is higher per horse-power in the first place, say £20 per brake horse power, or £200 for a 10 b.h.p. steam plant, wages remain same. The economy will be less, so that 25 per cent. more for coal, oil, etc., must be allowed than for the larger plant.

Tabulating these results, we get

TABLE II.

A.—INVARIABLE COSTS.

	B.H.P. per annum.	B.H.P. per hour.
Interest on outlay, £200 at 4 %	£0 16 0	·120 penny
Depreciation „ „ 7½ %	1 10 0	·064 „
Repairs „ „ 5 %	1 0 0	·080 „
Wages of driver, £100 per annum	10 0 0	·800 „
Total	£13 6 0	1·064 pence.

B.—VARIABLE COSTS.

5lb. of coal per hour for 3,000 hours, using coal at 15s. per ton	£5 0 0	·4 penny.
Water, oil, waste, sundries, etc.	1 5 0	·1 „
Total	£6 5 0	·5 penny.

So that total cost per Brake Horse-Power per annum = £19. 11s.
and „ „ bour = 1·56 pence.

This is just about double the working cost of the large plant per Brake Horse-Power Hour, or looking at it from another point of view, the large plant will yield four times the power at only double the cost, since 40 × £10 = £400, and 10 × £20 = £200

Now let this small plant run for only 1,500 hours per annum, we have £13. 6s., which remains constant, and a proportional cost for the rest. That is

$$\frac{6\frac{1}{4} \times 1,500}{3,000} = £3\tfrac{1}{8} = £3.\ 2s.\ 6d.$$

and £3. 2s. 6d. + £13. 6s. = £16. 8s. 6d. per annum. This is equal to 2·9 pence, or nearly 3 pence, per brake horse-power per hour.

(To be continued.)

ELECTRIC POWER IN MINING.*

BY IRVING HALE.

There is a genuine fascination in the modern applications of electricity to the needs of business and social life—to the transmission of messages over continents and seas by means of the telegraph; to the transference of the human voice, with all its individual peculiarities and inflection, through the telephone; and to the illumination of cities by electric currents distributed from a single station. But none of these appeal as strongly to the imagination as the transmission of power by this mysterious force. When we watch a ponderous engine, with its strong rods and cranks of steel and massive flywheel, anchored to a foundation of solid masonry to resist the vibrations produced by its mighty efforts, it is easy to appreciate the enormous power that is being developed; but when we are told that all this power is required to revolve a bundle of wires in the open space between the poles of a magnet, and that in those wires nine-tenths of this mechanical energy is converted into electrical energy and passes out of the building on a few small wires which undergo no strain and give no visible evidence of the work that is being done within them, and that this electric energy can be transmitted for miles and reconverted into mechanical power, we cannot fail to be impressed with the remarkable nature of this transformation and the possibilities which it involves.

The advantages of producing power where it can be done at comparatively small expense, either with water power or cheap coal, and transmitting it to places where water power is not available and fuel is expensive, are so evident as to require no discussion, and it is obvious that there are few places offering better fields for such operations than the mining districts, where water power is generally available within a few miles, but seldom at the mine or mill, and where the cost of coal is almost always great. Moreover, electricity is peculiarly adapted to underground work, where steam is objectionable on account of inconvenience of pipes, loss by condensation, and heat produced, while the transmission of power by compressed air is inconvenient, expensive, and wasteful.

Indeed, so striking are the advantages and possibilities of electric transmission of power that there has been a strong tendency to exaggerate and to allow the spirit of prophecy to override conservative judgment. For instance, while it is theoretically possible to run the factories of Chicago by power transmitted from Niagara Falls, and while it is possible that a small plant of this kind may be installed at the World's Columbian Exposition as an illustration of what can be accomplished, still in the present state of the art such an enterprise would not be commercially feasible, nor is it likely, with all the improvements

* From the *Engineering Magazine*, New York.

that will be made for many years to come, that the power of Niagara will be felt beyond a radius of a hundred miles. It is not intended to imply that this distance is necessarily the limit of successful and profitable transmission of power by electricity. It is quite possible that in the near future plants may be in commercial operation over even greater distances, but they will be in localities where fuel is sufficiently expensive to make the saving pay interest on the large investment required.

The question is frequently asked, "How far can water power be successfully and profitably transmitted by electricity?" The answer depends upon many conditions. In one situation it might not pay to transmit power a mile, while in another it might be transmitted 50 miles and pay large dividends on the investment. The principal conditions affecting this question are the cost of water power, cost of fuel where power is to be used, amount of power required and number of hours used per day, and, lastly, the voltage or electrical "pressure" that can be employed satisfactorily. When it was discovered that the dynamo, which generates an electric current when its armature is revolved by some extraneous power, becomes a motor and will do work when a current is sent through it from another dynamo, and that this action can take place regardless of the distance between the two machines, the feasibility of transmitting power by electricity was at once recognised. In the enthusiasm over this discovery and its possible effects there has been quite a general tendency to overlook the important question of dollars and cents, which is the criterion by which the fate of every purely engineering or business enterprise must be determined. The manner in which the financial aspect of the question is affected by distance, voltage, and the other conditions named can be more clearly shown by a brief examination of some of the principles governing electric transmission of power.

The total efficiency of an electric-transmission plant (ratio of power delivered on motor pulley to power required to run dynamo) is usually between 60 and 70 per cent., there being a loss of 10 or 12 per cent. in converting mechanical into electrical energy in the dynamo, a similar loss in reconverting electrical into mechanical energy in the motor, and a loss in the line depending on the relation between the size of wire and the current transmitted. This line loss (due, not to leakage, which is insignificant in a properly-insulated line, but to the waste of energy in overcoming the resistance of the conductor) may be made as small as desired, no matter how great the distance, by using sufficiently large wire, but this involves additional expense, and it is evident that for each case a point will be reached where farther increase in size of wire would be inadvisable, as the interest on additional cost of copper would exceed the value of the power saved. In most cases the best loss in line, all things considered will be between 10 and 20 per cent., which, with the losses in dynamo and motor, will give a total efficiency of 60 to 70 per cent.

The energy lost in line is dissipated in the form of heat, and the amount of energy so dissipated is equal to the square of the current multiplied by the resistance of the wire, this law being expressed by the equation $H = C^2 R$, in which H represents energy converted into heat (measured in watts), C represents current (in amperes), and R resistance of wire (in ohms). As the resistance of a wire varies directly as its length and inversely as its cross-section, this resistance (and consequently the line-loss) will increase with the distance, unless the cross-section of wire is increased as rapidly as its length, which means that the weight of wire will increase as the square of the distance, and that its cost will soon become prohibitory. To keep the weight of wire constant as distance increases, the area of cross section must be correspondingly decreased which will make the resistance increase as the square of the distance. To keep the line loss constant, the equation shows that C^2 must be correspondingly decreased, which requires it to vary inversely as the square of the distance or C to vary inversely as the distance. How can this be done and still transmit the same amount of power? The answer to this question is suggested by the formula for the energy of an electric current, W (energy) = C E, E representing E.M.F., commonly called voltage or "pressure," measured in volts. This equation shows that the same energy may be transmitted by a small current, provided the "pressure" is correspondingly increased (an analogy to water power), and from what precedes it is evident that, if the E.M.F. increases in the same ratio as the distance, a given amount of energy can be transmitted with the same loss and the same total weight of wire, regardless of the distance.

This apparent avenue of escape from the difficulties of long distance transmission is again blocked by the objectionable features of the high voltage or "high tension" current, chief among which is the difficulty of manufacturing dynamos and motors which will be proof against the almost uncontrollable desire of such current to puncture insulating materials, produce "short-circuits," "grounds," and "burn-outs," and make uncalled-for pyrotechnic displays around the commutator.

A partial solution of this difficulty is expected from the "three phase" system recently experimented upon in Germany, where power was successfully transmitted from Lauffen to Frankfort, a distance of 108 miles. In this system the dynamo generates an alternating "three phase" current of large "quantity" and low "pressure" or voltage, which is converted by a transformer into a current of small quantity and enormously high voltage — 20,000 to 30,000 volts if necessary — that can be transmitted over a comparatively small wire and reconverted at the other end into a low voltage current which operates the motors. The advantage of very high voltage in transmission is secured while avoiding its disadvantages in dynamos and motors. While the Lauffen Frankfort installation was a scientific experiment rather than a commercial enterprise, still the results obtained are regarded as very encouraging, and the development of this method is expected to exert a powerful and beneficial influence on long-distance transmission. It must not be forgotten, however, that the transformers at both ends of the line add materially to the cost of the plant, and that the pole line and labour for such a distance, regardless of size of wire, become a serious item of expense, and that consequently electric transmission to very long distances must still be limited to cases where fuel is comparatively expensive and the saving is sufficient to pay interest on the required investment.

The foregoing discussion shows how the distance to which power can be transmitted profitably is affected by the question of voltage. The other conditions mentioned as affecting this problem require no detailed discussion, as it is evident that the saving effected by water power over steam will be greater when water power is cheap, fuel dear and the work continuous, than when reverse conditions exist, and that the greater this saving the greater will be the justifiable investment in electric plant and the distance to which power can be profitably transmitted.

Equations and curves have been deduced showing in a general and approximate manner the cost and operating expenses of electric transmission plants and the limits within which they will be profitable (pay 20 per cent. on investment) under various conditions. A few examples may be of interest here. If coal costs 4dol. per ton and power is used 10 hours per day, 200 h.p. can be electrically transmitted four or five miles at 1,000 volts E.M.F. and pay 20 per cent. per annum on the investment. If used steadily 24 hours per day, it can be transmitted 11 or 12 miles under the same conditions. If 2,000 volts can be conveniently used, these distances will be nearly doubled; in fact, the limiting distance will increase almost in proportion to the voltage employed. Looking at the question from another standpoint, it may be shown that if coal costs 6dol. per ton at a mill where 100 h.p. is used 24 hours per day, and water power can be developed at moderate cost at a distance of five miles from the mill, and there is no objection to using an E.M.F. of 2,000 volts, the saving effected by using electric power will pay 50 to 60 per cent. per annum on the cost of the plant. If, however, this mill is in a locality where slack coal can be obtained for 1dol. per ton, and power is used only 10 hours per day, it would not pay to instal an electric plant if water power could be had within a quarter of a mile, as the saving would not pay interest on cost of water power, dynamo, and motor, without any line

whatever. Examples might be multiplied indefinitely, but the instances mentioned are sufficient to show how impossible it is to give a general answer to the question, How far can power be profitably transmitted by electricity? and how necessary it is to carefully weigh all existing conditions. The cases cited show, however, that, whatever may be the limiting distance to which power may eventually be transmitted profitably by electricity, there is at present a wide field for enterprises of this kind, presenting an attractive investment for capital, and nowhere are the advantages of electric power more striking than in the mining districts.

Aspen, Colorado, is entitled to the name of the pioneer camp for electric mining machinery. The first electric hoist was installed there in 1888, and consisted of one of the earliest types of Sprague street-car motor geared to a flat friction hoist. It has been in use ever since, and is still giving satisfactory service. There are now at Aspen five electric hoists, three electric diamond drills, three electrically-driven blowers for ventilating, a 20-h.p. motor running the sampling works, and several smaller motors used for various purposes, while many of the mines are lighted by incandescent lamps. The Aspen Mining and Smelting Company operates its own plant, consisting of two 50-h.p. dynamos supplying current for three hoists, one diamond drill, one motor driving a blower, and another running a machine shop, as well as lights for the tunnels and workings. The other electric machinery, together with more than a hundred arc lights and nearly 3,000 incandescents for town and mines, are supplied from the plant of the Roaring Fork Electric Light and Power Company, which is one of the most interesting on the continent, and is a good example of the mountain style of water power and electric plant.

The mining town of Aspen is situated on Roaring Fork at its junction with Hunter Creek, a small stream that tumbles down the ravine on the north-west side of Smuggler Mountain, on which are situated such famous mines as the Smuggler, Johnston, Della S., and the fabulously rich Mollie Gibson. On Hunter Creek, about 2½ miles from its mouth, a small dam is built, the principal objects of which are to give a sufficient body of water to avoid stoppage by surface and anchor ice and rubbish, and to provide a small reserve of water to tide over the early morning hours, when mountain streams fed from the melting snows are lowest. From this dam extends a flume 24in. by 18in., a distance of 9,000ft. to a point on Smuggler Mountain, 876ft. above the power-house, which is located near the bank of Roaring Fork a little above the mouth of Hunter Creek. From the end of the flume a wrought-iron pipe 4,500ft. long extends straight down the mountain and across the gentle slope at its foot to the power-house, where it supplies water through nozzles to eight 2ft. Pelton wheels, rated under this head of 876ft. at 175 h.p. each, which run the dynamos for supplying light and power. In the small view of the power-house is also shown the waterwheel governor, designed by Mr. Doolittle, manager of the company, which, by means of differential gearing, utilises the difference in speed between a wheel with steady load and the wheel to be governed to move the nozzle of the latter wheel and vary the amount of water delivered against the buckets.

The quiet little stream flowing from the power-house gives no indication of the vast power that it has just been the means of generating, but this power can be appreciated by raising the covers from the wheels and looking at the water as it is hurled from the nozzles against the buckets, and if any further evidence of its terrific force be required, it can be obtained by attempting to pinch one of these little jets between the thumb and forefinger. The spray on its surface presents a velvety feeling to the touch, but when the fingers have sunk into the jet $\frac{1}{16}$in. it is as hard and impenetrable as if it were frozen, and it is said to be impossible to cut it with an axe.

Probably the most remarkable electric plant in the country, all things considered, is the one at the Virginius mine, near Ouray, Colorado. The water power is located on Red Cañon Creek nearly four miles from the mine, which is near the top of Mount Sneffles, far above timber-line in the region of perpetual snow, and at an altitude of 12,700ft. above the sea. The idea of transmitting this water power to the mine by means of electricity, at a time when such an undertaking was regarded as a somewhat doubtful experiment, was very forcibly suggested by the fact that coal had to be packed to the mine on burros and cost delivered about 20dol. per ton, or 100dol. per day for the amount of power used at that time.

The power plant is similar in its general features to the one at Aspen, just described. From the power-house the line extends for some distance up the cañon through dense timber, where the wires are subject to the danger of falling trees blown down by the terrific wind-storms which prevail in that locality. Leaving the cañon, the wires are carried up a precipitous bluff, ornamented here and there with the carcases of burros which have slipped or been crowded from the narrow trail known as "the zigzag," effectually disproving the commonly-accepted theory that it is impossible to kill a burro. From timber line, at the top of this bluff, the line is built across a rocky plateau, where the snow during the first winter covered the tops of some of the poles, which were at that time only 20ft. high, but which have since been replaced by longer ones. For the last half-mile or so the poles are set along the base and on the sides of high cliffs, to avoid as far as possible the destructive snowslide. The current is carried down the mine by the best waterproof cables, boxed for mutual protection of wires and men, the electric pressure, 800 volts, being a little too strong to suit the taste of the average miner. The power, about 250 h.p. in all, is distributed among two pumps, one hoist, one blower, and two mills. It will be seen that this plant comprises nearly all kinds of machinery employed in mining operations, and encounters every difficulty to which electric plants are heir, including the worst enemy of electric machinery, lightning, in its most violent form. It is not surprising that troubles were experienced in the early operation of the plant, but the gratifying facts that these have been remedied and that the plant is running in a perfectly reliable and satisfactory manner are evidence that electricity in mining has come to stay.

It is a conservative statement that there are, in Colorado alone, hundreds of mines using steam power produced by very expensive fuel that are sufficiently near to good water power to be operated by electricity at a saving that would pay from 40 to 100 per cent. per annum on the investment, and it is not a wild prophecy to say that within the next three years scores of such plants, developing thousands of horse-power, will be installed.

The effect of such enterprises will be powerful and widely felt. By decreasing the cost of mining and treating ores, mines which now pay will pay better, while many properties which, on account of low-grade ore or remoteness from railroads and fuel supply, cannot now be worked without a loss can be made by means of electric power to yield satisfactory profits. The effect will be to increase the metal output, give employment to more men, build up the mining towns, exert a beneficial reflex influence on the commercial cities, and, in general, benefit the entire mining districts.

Next to the silver question, the introduction of electric power is at present the most important factor affecting the development of the mining industry, and, unlike free coinage, electric power is not dependent on legislative action, but is entirely under the control of the mining men themselves.

Electrolytic White Lead.—The chairman of one of the largest white-lead companies, on being questioned recently, said that "nothing had yet upset the good old method" of obtaining white lead. Numerous experimenters are, however, on the track for the fortune that awaits the lucky inventor of a better and cheaper process is immense. The process of M. Stevens recently described for obtaining white lead electrolytically is as follows: To water is added 300 cubic centimetres of nitric acid to make a volume of two litres. The anodes are plates of lead 3 mm. thick. If the metal contains silver, the silver is deposited on the cathode, and can be separated. By passing a current of carbonic acid the white lead is precipitated.

Vols. I. to IX. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, red, price 8s. 6d. Subscribers can have their own copies 2s. 6d., or covers for binding can be obtained, price 2s.*

EDISON'S PATENT RE INCANDESCENT LAMPS.

The exact position with regard to incandescent lamp patents is becoming more and more interesting every day, both here and in America. In this country, however, opposition manufacturers to those controlling the Edison-Swan-Sawyer patents are a thing of the past, and would-be producers are waiting with what patience they can command the lapse of the patents. In America the case has been somewhat different. Legal fighting in regard to the Edsion patents has been going on for years, and it is only within the past few days that the decision in the appeal case Edison Electric Light Company v. The United States Electric Lighting Company, has been given in favour of Edison. The patent of Edison under dispute is No. 223,898, filed November 4, 1879, and granted January 27, 1880. The four claims of the patent are as follows:

"1. An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance, made as described, and secured to metallic wires, as set forth.

"2. The combination of carbon filaments with a receiver made entirely of glass, and conductors passing through the glass, and from which receiver the air is exhausted for the purposes set forth.

"3. A carbon filament or strip coiled and connected to electric conductors so that only a portion of the surface of such carbon conductors shall be exposed for radiating light, as set forth.

"4. The method herein described of securing the platina contact wires to the carbon filaments and carbonising of the whole in a closed chamber, substantially as set forth."

In our article on September 30, when discussing the lapse of the Cheesbrough patent, No. 4,847, November 28, 1878, we spoke of Edison, Swan, and Sawyer as a triumvirate to which was due the commercial incandescent lamp of to-day. Nine-tenths of the litigation on patent questions is caused by the frailty of humanity, the inherent longing which every human being seems to possess of putting his hands into his neighbour's pockets. A new departure was given to incandescent lamp making with the introduction of filaments and flashing. Immediately satisfactory results were known, hundreds of "so-called inventors" set to work to see if they could devise an "improvement" which they could patent, and so get round the patent of the original inventor. Not one of these hundreds had knowledge or sense enough to start an investigation *de novo*. They were simply sheep following the bell-wether. They commenced to make and sell lamps, and the pioneers had to fight for their rights. In England case after case was fought and won. In America case after case had to be fought, the final result being delayed till now. There are two people the world should delight to honour, but in most cases the attempt is to rob—give all honour to the initiator or initiators of a new departure that confers benefit to poor humanity, and give as great honour to the man or men who make that departure commercially practicable. We do not include in this latter category company-mongers, who are the sharks in the sea of civilisation. It may be that Edison and Swan have reaped great

pecuniary advantages, but surely the world and the electrical industry have nothing to declaim against this, seeing that the one has obtained "subdivision," and the other has participated in the gains of an industry which is destined to be without equal in the world's history. Without incandescent lighting central stations would never have come into general existence. The views relating to power transmission and the utilisation of electric energy in every household would for years, if not for centuries, have remained in abeyance. Thus we think that the law both in America and in England has, whatever its tediousness and intricacies, come to a right decision in the end. If the monopolists were wiser in their generation, they might, however, have legislated more for the future than for the present.

A NEW SYSTEM OF MAINS.

We understand that Messrs. J. E. H. Gordon and Co. will probably next week make public, through the medium of the technical press, their new system of mains, devised by Mr. Tomlinson, which it is thought may go a good way towards reducing the cost of copper in conductors. From the moment that incandescent lighting became practical, it was seen that the cost of copper in mains would form a large item in the initial expense of central station work. Originally we had a lead and a return. Then Prof. John Hopkinson on this side of the Atlantic, and Mr. Edison on the other side of the Atlantic, devised the three-wire system — or the *n*-wire system whereby a large amount of copper might be saved. This system might well be called a differential system, and it is in common use throughout the whole world. We do not know how the new system is to be named — probably, however, by the best known name of the company under whose auspices it is brought out. By its means it is hoped that the third wire in the three-wire system may be saved, reducing the mains to two, as in the oldest form; but with the great advantage of saving a large amount of copper over the original system.

Of course, there is some little difficulty in deciding the value of a new departure till full details are known, and these depend upon Patent Office formalities. We are told that the system has been tried successfully, and that the important feature is in the use of a one-to-one transformer, which, so to speak, acts as a balance. Those who have carefully examined the cost of this, as compared with other systems, are confident that it will effect a very great saving, and must be extensively adopted. It is quite evident to all who know anything about central station work that every pound saved initially will greatly assist extensions. This saving, however, must not be at the expense of efficient maintenance, for, as we have so often contended, an extra initial expense is as nothing compared with the constant drain of inefficiency. There seems, however, no doubt as to the gain both initially and without detriment hereafter in everything that tends towards perfection in mains.

CORRESPONDENCE.

"One man's word is no man's word.
Justice needs that both be heard."

RE LEEDS ARC SYSTEM FOR MILLS.

SIR,—Doubtless many of your readers will, like myself, have eagerly perused the article and illustrations in your issue of the 14th inst. to see if it was anything in their way, or of any advantage, commercially or educationally, to themselves.

We are generally under deep obligation to gentlemen who place the result of their experiments before their *confrères* through a technical journal, yet when one sees what strikes him as a possible abuse of the apparatus or system described, he may perhaps be excused for rushing to pen and ink, leaving it to your discretion to put it into print or the editorial waste-paper basket. This is my excuse for this intrusion on your space.

What strikes me as the abuse referred to is the proposed introduction of the system described into mills and factories. Is it suitable for the majority of such? From my knowledge of Yorkshire and Lancashire textile mills and machine shops, I should say decidedly, no. Suppose we want 20 arc and about a dozen 16-c.p. incandescent lamps (not an outrageous demand), we must have at least 1,000 volts *within the mills*. In the mills I refer to, my experience leads me to believe that, owing to causes connected with the work carried on and often poor state of repair of the building itself, faults in insulation at the fittings, putting on an "earth" or "ground" are more likely than not to occur, probably within 12 months of erection of the installation. It would then be quite possible to get an available E.M.F. of 1,000 volts to give a shock to any unfortunate mill hand who might, perhaps, in the discharge of his duties touch another bare or insufficiently insulated part of the circuit. Such faults, of course, should not occur, but when we take into account the possibility of small slips in installing, the carelessness of workmen, and, worst of all, the all but irresistible pressure often brought to bear on a small contractor to take work at far too low a price, who can say we are safe? If faults occur with 100 volts, what may we not expect with ten or twenty times that voltage? In central station plants we can have frequent if not constant testing. In private installations, who would pay for it? Altogether it seems to me we should, in bringing high tension into buildings where experienced electricians are not always in attendance, be courting a repetition of the accidents we heard of not so very long ago (principally from the other side of the herring pond) which we all so much deplore. Is it wisdom to run this risk to save a hundredweight or so of copper? which, by the way, need not be nearly so extensively insulated with a low-tension system as a high; and your statement in this head appears to me much exaggerated, save for exceptional cases, so far as applying to mills and factories.—Yours, etc.,

A. W. BENNETT.

CARLOW.

SIR,—I fear your references to Carlow, as quoted from the catalogue of Messrs. J. E. H. Gordon and Co., have been dictated more by zeal than exactness.

You say the TOTAL revenue of the gas company amounted to about £1,700, of which the electrical works have secured £400 during the first four months. Having the balance-sheet of the gas company for the year ended March 5, 1892, before me, I find—

Gas rental amounts to ..	£1,560
Meter " "	58
Residuals	316
Sundries	70
	£2,004

which would not bear out your remarks.—Yours, etc.,

Cork, Oct. 16, 1892. JUSTITIA.

[It should have been "total revenue from *rentals*."—ED. *E. E.*]

One of the front rank firms in their own special department electrical fittings—is that of Messrs. B. Verity and *Sons*. This firm, established many years ago, was at one time split into Verity and Sons and Verity Bros., but competition under the same name not suiting either party the success of the amalgamation which was carried out has

long since proved the wisdom of that step. Business has grown with the extension of electrical engineering, and the firm, besides their original offices, showrooms, and factory at 31 and 32, King-street, Covent Garden, have now the West-end showrooms at 137, Regent street, a wholesale showroom at Heddon-street, Regent-street, and large manufacturing works recently established, and now in full swing, in Birmingham, known as the Plume Works, Aston.

Messrs. Verity have recently placed upon the market, at the price of 7s. 6d., what they term a "Compendium," likely to be of use to all electrical contractors. This must not be mistaken for a new fitting, a complex switch, or coupled set of dynamos or engine—or, in fact, the trade name for any new article. It is their distinctive name for a catalogue, and the full title is "Verity's Compendium of Electrical Appliances." Having become known more particularly as the designers and manufacturers of high-class ornamental fittings, brackets, electroliers, and so forth—as, indeed, their telegraphic address, "Electrolier," would serve to show—it might be thought that this catalogue contained a full and complete illustrated list of these handsome articles for the fitting of mansions. But no; this is to come. A sumptuous and delightful catalogue of Verity's art fittings is promised, and is, we believe, in the press. But at present we have to deal with the mechanical and useful electrical appliances—from boilers and engines to sockets and bell knobs; nay, even medical electrical appliances find a full place therein. Besides being large manufacturers, Messrs. Verity are factors—merchants and shippers—of every conceivable kind of electrical plant and fitting, and apparently wish so to be known. For the "Compendium" is not only a list of their own manufactures—though in this article we shall give most attention to this part—but it contains a full and classified illustrated description of the better known forms of electrical plant of all kinds, and, by their large connection, the firm have special facilities for this class of business at manufacturer's prices. For those who wish to possess this extended outlook we will describe the contents and then pass to the illustration of some of the newer fittings.

Patent water-tube boilers of the type of which over 800,000 h.p. are now in use, occupy the first page; full information is appended as to their construction, economy, and ease of transport, a special type being supplied for colonial use, where facility of transport is desirable and the cost of freight is high. The ordinary Cornish and Lancashire boilers of good make are shown. Engines of a high class make—compound horizontal semi-portable, vertical with boiler, and others—are shown, as well as high speed of Willans's and Armington Sims's make. Worthington pumps for feed-water comes next, and "Household's" patent water-lifter or steam jet pump for raising water with either low or high pressure steam. Oil engines and the "steam turbine" dynamo occupy a page apiece, and then we come to "Victor" turbines in many forms, specially suitable for dynamo driving. Snow's waterwheel governor is used with these. Dynamos naturally occupy a large space, and the following types are shown and recommended: Victoria, Manchester, Elwell-Parker, Castle, Phœnix, Goolden, Oldham, and Tyne machines. Combined self-contained portable plants receive attention, and a very full set of the various applications of electric motors is shown; we have electric draining pumps for mines, rotary coal or rock drills, gear-driven continuous-rope hauling engines, mining motors, electric ventilators, electric triplex pumps, electric launches, with a special department for electric traction, showing the Bournbrook system of trams. Accumulators of the well-known type are fully illustrated, with fittings, charging switches, cut-outs, and so forth, and portable batteries and hand lamps, which are now beginning to be very widely used, are illustrated in the most useful forms. After arc lamps, incandescent lamps, instruments, and switchboards, we come to some interesting types of special fittings, many of them quite new, some of which we illustrate herewith.

Nothing better or simpler for large low tension currents can be used than the well known "knife" switch, which Messrs. Verity make in large sizes, ranging from 150 to 1,000 amperes. They are strong, and have no parts to get out of order. They have large surfaces, cleared at every contact, and the current passes through no joints. They are to be recommended for main switchboards in station work, and are made for double-pole break, and also for changing over from an ordinary to a three-wire circuit. A main switch much in use for smaller circuits and private installations is Verity's patent main switch, with automatic quick-break action. They are fitted in cast-iron frame, with slate or china centre, double-pole break, with china cover. They are made usually in sizes from 20 to 50 amperes.

Considerable attention has been given to richly-decorated switches for branch and lamp circuits in houses. First-class designers have been set to work to produce switch covers of an artistic kind in Italian, Renaissance, Elizabethan, or other decorative style to suit the surroundings. These switches are made in three different actions—side lever, tumbler, and ordinary twistle handle shape. They are made in silvered, gilt, black, or cream china, and being fitted with ivory handles, make very suitable switches for high-class mansion installations. They are made to carry three, five, or ten amperes.

An interesting novelty for fitting in dark corners or in bedrooms is the luminous switch (Towle and Langdon's patent). These switches are provided with an application of luminous paint, so that they become visible in the dark. They are particularly applicable for switches in hotels (and the spare rooms in private houses), where the rooms are frequently used by strangers, who may otherwise be obliged to fumble about for a long time, and, perhaps, bark their shins over the furniture from not knowing the exact situation of the lamp switch. An ordinary switch can be mounted on a luminous base, which is supplied separately if desired.

We now come to the question of safety fuses. Here Messrs. Verity excel, for they offer some types of cut-outs of an exceedingly useful and well-organised description. The desiderata in a cut-out are that it should be fireproof, easily fixed, the fuse should be easily replaced, and that it should be impossible for a fuse of a larger conducting power than that desired to be inserted in the fuse box. In Messrs. Verity's double safety fuses we have these requirements carried out in a simple manner, which can easily be seen in the illustration. The fuse-box—either single or double-pole, as desired—is made with metal contact tubes, into which a fuse-plug can be inserted by the pressure of the finger and thumb. The fuses are marked with conspicuous figures to indicate the current they carry, thus: 1-2, 2-4, 4-6, and so on. These fuse-slips are each made to a certain length and thickness, those carrying the higher currents being the largest. The slots in the fuse-boxes are made to fit one size only, and it is absolutely impossible to insert a large fuse into a block intended for a small circuit. It is thus impossible, either by design or inadvertence, to use the wrong size of fuse, except by actually unscrewing the box and fixing another. The fuses are placed in position easily after the house is wired without tightening or loosening any connections. They deserve to be very widely used and specified.

Theatre fittings have received considerable attention on the part of this firm, who have fitted up several of the large London theatres. They make a number of special fittings, consisting of large shoes and plugs let in flush, or for hand insertion. A shoe and plug, with handle, is largely used for stage work where temporary connections for a large number of lights is necessary, the stock size being for 50 amperes.

One of the first necessaries in installation work is insulated wire, and these are dealt with in a detailed manner. The directions given in the "Compendium" for jointing may be worth quoting for those who wish to do their own jointing: "First strip the insulation back for a few inches to allow sufficient space for soldering without injury to the indiarubber. Then solder. In stranded wires it is advisable to wrap the strands with a spiral of tinned copper wire. At any rate avoid all sharp points, and do not allow ends of wires to stick out, or they may pierce the pure indiarubber. After soldering (without acid), cut back the insulation of cable or wire to a taper form. Rub a very little rubber solution on the wire itself and the

tapered ends of the original rubber insulation; then wrap with pure rubber strip from one end to the other and back, so as to give at least three layers of pure rubber. Be careful not to use too much solution (more than above mentioned is liable to work injury), and in tapping the pure rubber a continuous and heavy strain should be kept up, causing a small film of solution to ooze through between the lappings. This is quite sufficient to render the three layers of strip adhesive, and, ultimately, homogeneous. The strip should be thoroughly over-lapped on itself. After thorough lapping with pure rubber, two or more lappings of double-proofed tape should be wound on in a similar manner as tightly as possible. The last end should be fastened by a slight application of solution. The following are the four important rules in jointing: (1) Avoid acid in soldering; use resin. (2) Do not use too much solution. (3) Lap the rubber strip as tightly as possible (4) Cleanliness is of the utmost importance. Where possible the work should be divided so that one operator does the cutting away, another the soldering, a third the pure rubber lapping, and so forth. It is certain that a man with his hands smeared with solution cannot make a clean joint."

Perhaps one of the minor points in electrical practice that has received the largest share of the attention of inventors is that of the construction of ceiling roses. The rush is now, and rightly, for what has become known as "high insulation" types of china fittings. Messrs. Verity have a ceiling rose of their own type which has many points to recommend it. They are made of porcelain, the base having a double plate, one being used for fixing to the ceiling and the other for electrical contacts. They thus avoid possibility of leakage to earth from the terminals, as none of the terminals pass through the base. The china or brass cover is placed over and fixed down by a nut screwing on the top of the china pillar. A number of lamp fittings and their parts are shown, so that contractors may make up their own pendants if desired. A very useful fitting is the patent swing joint for electroliers and combination gas and electric pendants. It is easy to fix—the wires are hidden and the pendant always hangs vertical A fitting that is very widely used is the silvered reflector to clip round a 16 c.p. lamp. Another fitting, very useful in hotel and club lavatories, is an automatic door catch which lights the lamp when the door is closed.

A large number of very tasteful globes, glass and silk shades are shown. These being well known, need no illustration. But a fitting more novel, and, we should think, very useful, is the plate-glass convex reflectors, Timmis's patent. An ordinary lily or floral shade is carefully moulded to give a certain required angle of reflection, and the inner surface is silvered. The consequence is that lamps with which these reflectors are used give some 30 per cent. more downward light. They are very suitable for office and library use.

Amongst the numerous smaller appliances described and illustrated, there are comprised nearly everything that a householder or contractor can require electrically. Small sets of dynamos and lamps, for five to 20 lamps, are largely used abroad for tea sorting, and in works and offices Linesmen's tools are largely illustrated, wire-drawers, soldering furnaces, tools for cutting lead covering of cables, and so forth. The patent insulating material known as cellulvert was first introduced in this country by Messrs. Verity, and is highly recommended by them. Telegraph instruments are now made in large quantities, many of the large railway companies being their customers. Bells of all kinds and telephone sets receive necessary description, and the "Compendium" ends by a very wide assortment of electrical medical apparatus of special manufacture, English and foreign, for which the firm are now agents. An exhaustive index completes this very carefully-compiled catalogue, and amply illustrates the very wide field over which electricity now ramifies.

Theory of Accumulators.—M. Bidard, professor of chemistry at Rouen, has brought forward a new theory of accumulators, publication of which is promised shortly.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE III.

(Concluded from page 386.)

The lines of force, in cutting through the wire of the armature, induce electric currents in the wire, of course; and since the armature opposes the creation of these induced currents in the wire, a natural mechanical opposition is offered to these wires being cut by these magnetic lines of force; and the consequence is, the armature is carried bodily round, and tries to turn round at the same rate at which the magnetic field is travelling round, in which case the conductors would not be cut at all by the lines of force That is the general principle of the machine, which was independently invented by Ferraris, of Turin, and Mr Tesla. The results of the official experiments which were made at Frankfort have not yet been published, and consequently we are hardly in a position to speak of the value of them; but I may say that we have not the slightest doubt that this system of multiphase transmission is an extremely effective mode of transmitting power, and that it opens a new field, and is equally suitable for distribution and for transmission, and in that way has an enormous advantage over the simple alternating-current system with synchronising motors. It has all the advantages of simple alternating currents, in that we can use low-tension dynamos, which are perfectly safe things to deal with, and which can be made of thoroughly mechanical construction; we can increase the pressure by means of a transformer, and carry the power to a distant station; lower the pressure there to such a pressure as is convenient for distributing through a town, and then take it off at the houses where the motive power is required, and drive our motors. That is to say, it has all the elasticity of the ordinary alternating-current system; and its motor has the enormous advantage over the synchronising motor in that it is a machine which is suitable for placing in workshops—one which you can start and stop as often as you please.

One of the greatest uses of electrical motors in workshops with which I am acquainted is their use for cranes, especially travelling cranes. There are many other cases where it is highly useful for replacing shafting and for the working of machinery. In all these cases we need to be continually starting and stopping the motor. We cannot leave the motor continually running; and it is essential for these purposes to have some motor like this rotating-phase motor, in which we can start frequently and effectively. We have had no tests published of the Frankfort trials as to the power of starting, but I may perhaps interest you by giving you, in concluding this lecture, a few results of experiments which I made this afternoon with such a rotating-phase motor, as I do not think that any results have been published at all. I will only just give you one or two results. I will give you one just to show you what work the machine was doing. It was not doing a very great deal, but I will give you an example of what it was doing. The alternating generator was driven by means of a continuous-current motor, the current being supplied to it from the mains of the Westminster Supply Company. That alternating generator supplied alternating currents to one of these rotating-phase motors. That motor in turn was caused to drive a continuous-current dynamo machine, and it supplied a number of lamps. We were able to measure the volts and amperes which came in from the Westminster Company, and the volts and amperes which went to the lamps, and we could get an idea of the amount of work which was being done by this motor.

With the first continuous-current motor we had 102 volts in one experiment and 39 amperes. And on the lamp circuit where the work was being done we had 89 volts and 9½ amperes. That shows that we were getting something over a horse-power from the motor. That is the only reason that I put down these figures. You must not take these figures as representing the efficiency

* Cantor Lectures delivered before the Society of Arts.

of the alternating motor in the least degree. They give us no information on this, because, in the first place, it was an inefficient motor which we were using to drive the alternator, and it was an extremely inefficient dynamo which we were using to generate the current for the lamps, so that we had really no test of efficiency whatever. But it gives you an idea of the horse power which we were using. The motor was a motor which was giving us off about 1 h.p. in the lamps, but it was working up to a higher figure. Now an interesting experiment was to find what power there was at starting, and I found that on a pulley having a diameter of about 5in., there was a pull of about 40lb., when the alternating motor was supplied with current at the same pressure as in the previous experiments; that is to say, in the ordinary working of that alternating motor as at that time, we would get a pull of about 40lb on a pulley of 5in. The speed at which we were going in this experiment was 1,380. Now the pull at 40lb which I found on the pulley would have given us 2 h.p. at that speed. Consequently the torque at starting was extremely good; and although this is a very rough experiment, it is of the greatest interest to myself to have the measurement of the starting torque with such a motor, because I have not been able to get any other actual measurements of any sort whatever. We shall get more accurate experiments very soon no doubt, but this is the first step in the right direction.

Lecture IV.

In my last lecture I was dealing principally with the question of using water power in connection with electric lighting and electric power. There are two engineering problems, important to engineers, in connection with the use of water power; one is, where we are using it simply for lighting up a very small place, and one frequently has to deal simply with the lighting up of a single country house.

The extreme case, on the other hand, is the transmission of power to great distances, where you want to utilise a waterfall, and bring the power into a town and use it there for motive power or for lighting. These are two very distinct problems, and there are several points in each of them that need particular attention. It may be worth while to introduce a word of caution in connection with the use of water power for lighting country houses. I have found from experience that the very greatest caution is necessary in utilising water power that may seem to be perfectly available. In the first place, it is generally extremely difficult to find out what is the exact amount of power which can be obtained from the source of the supply. Of course, the water power in this country is generally superabundant in winter, and diminishes in summer. That is a fortunate thing for us, and suits the demand for light; but it becomes extremely doubtful whether the supply of water which we can get in the very driest time of a dry summer will be sufficient for our purposes. I may say that, whenever it appears, from observations that you may take at any one time, that there is the slightest doubt it is the most injudicious thing to set up turbines and plant for utilising the water power without having taken measurements of the flow of water, at least during one summer, and thus judged as to the probability of the supply during a particularly dry summer. But there is another equally likely catastrophe to happen, which is far more serious and important, and that is that in a great many places, where it appears perfectly certain that we shall have enough water during the whole of a dry summer, there may come on a heavy frost in the winter, which will freeze up the source of a stream, and prevent us from getting our power in mid winter. The fatal effect of such a thing is evident, because it is in mid winter that we want our light most; but it sometimes happens that a small burn that we intend to use for electric lighting, which the inhabitants around may tell you certainly never freezes, and that the flow in winter is always superabundant, may sometimes be found to freeze, and you are deprived of water power in the very middle of the winter. In such cases, however, it very frequently happens that it really *would* be a saving of expense to introduce turbines, besides having an auxiliary boiler and steam engine for cases of emergency. It is a large additional expense to the original plant, but it is in most cases extremely useful and very economical, when we consider the saving that the water gives us in the consumption of coal during the greater part of the year.

But there is another point of economy which sometimes has not enough attention paid to it, and that is when the source of water power is not exactly on the premises or where you want the power to be used. It very often happens—in a country house, for instance—that the power is at a distance of, say, half a mile from the house. Now, even the distance of half a mile is serious, when you come to calculate the size of the conductors which will be required to convey your current from the source of power to the house. Too often people have gone upon the assumption that the cables would not have to be very large, and have been disappointed in this way, and have thus been led to very considerable expense.

With regard to the extreme case of using water power for transmission to a distance and, it may be, subsequent distribution through a town, I spoke pretty clearly on the last occasion; and while at the present moment most cases of transmission would be best done by means of the alternating current, I can quite see cases where the continuous current is the most applicable, and there is no reason why we should not transmit our 10,000 volts or so by means of a continuous current for such purposes, only taking far greater care for matters of safety, because the dangers of a machine with a commutator are very much greater than with an alternating-current machine. Of the means available for using the alternating current, as I have stated, there are two which may be considered, at the present moment, as decidedly the best. The one is by means of synchronising generators and motors, which are ordinarily alternating-current dynamos, working synchronously with each other; and the other is by means of the rotary phase system of transmission. I pointed out, at the end of the last lecture, that, while light alternators will not work well as motors when they are used singly, with a simple pair of conducting wires, you may use them in pairs, receiving two different currents in different phases from a similar pair acting as generators, one receiving its maximum when the other is receiving its minimum; that that arrangement enables us to get over the dead centres; and that such a machine, if it is extremely light, will start with a good pull from the beginning, and will do transmission work extremely well. Thus it appears that two Ferranti dynamos arranged in that way will make a generator of two currents, and will work as a motor also, and will work well, and will start well as a motor; whereas the Mordey alternator, which I contrasted with it in the ordinary way of working, has a very massive rotating part, and in consequence of that, it will not start as a motor as well as a light machine, when we are using two separate currents. Thus we have the curious fact that the heavy Mordey machine is the better as a synchronising alternator of the two, whereas the light Ferranti alternator is the better one, where you are using two currents in different phases.

Lately, in America, the dynamos which had been used for generating continuous currents for tramways by the Westinghouse Company have been fitted with rings for use instead of the commutator; four rings for taking off two alternating currents, one giving its maximum when the other current is giving its minimum. These large powerful machines have been working admirably as motors; they start very readily indeed, and, of course, continuous currents can be then taken off, on the same sort of principle as was shown by Mr Schuckert at the Frankfort Exhibition, which has been talked of a good deal since. That machine has been very largely adopted indeed, and has been doing admirable work.

Coming now to treat of another matter in connection with water power, I wish to draw attention to what has been done in Switzerland in the way of utilising water power. Last summer I had the advantage of travelling with Prof. Unwin through Switzerland, our object being to study the various cases where the natural power of water had been utilised for transmission to a distance,

pelled to increase the accommodation for that staff, as there were no houses at St. Vincent. They had also to erect tanks for their spare cable, and to extend their office accommodation, at a cost for the half year of £1,150. Then there was the cost of applying duplex to No. 2 cable, £3,000 of that cost falling due in the half year under review; but that would now be reduced to £500 for each half year for the next six years. He might inform them that the duplex had been of immense value to their working. Working both ways was a great benefit, and they could, when they think proper, work both ways on the next cable also. That brought the total decrease of expenditure to £2,929. With their permission, he would not refer to all the items of increases and decreases in the balance sheet. He would now refer to such criticisms as had come to hand from three of their proprietors. Out of 2,900 shareholders they had had three letters. Naturally they received such criticisms with all respect, and they considered among themselves whether their policy could be defended upon business principles in the best interests of the proprietors, the efficient maintenance of the property and the security, so far as it was possible, of their revenue for the purposes of dividends. For several years he had warned them that something like a crisis was coming, and now, at that moment, they were face to face with a rivalry which would test the wisdom of the policy of that Board since the formation of the Company 19 years ago. One honourable proprietor was of opinion that they ought not to make extensions out of revenue, but add all to capital, and that all such expenditure as could be properly debited to capital account should be so treated. Of course, as a matter of bookkeeping, there was much to be said in support of such a contention; but, if such a policy were adopted in practice, then farewell to quarterly dividends, and when, in the course of time, a large expenditure of capital became imperative, it could only be got upon such onerous terms as would postpone or destroy all prospect of any dividends upon ordinary stock, whereas, with a large reserve, such as they now had, and with a moderate amount of debentures, they could at once lay another cable if they desired to do so. They were in this position: their revenue-earning capacity was secure, even though a tariff war should be forced upon them. They would not willingly initiate it, but they were directly threatened with it, both on the west and on the east coasts. A reduced tariff, however, would, no doubt, increase the traffic, and besides being in a position to carry it better than any other company, if the fight were too hard they had the interest of their reserve to fall back upon for dividend purposes, if need be, as supplementary to their income from traffic. They were not exactly on their backs, if they had a great opposition, for they have that reserve of interest to fall back on, and they would not had to go without a dividend, even though they dipped into the reserve. They were not so weak, therefore, as their opponents thought—at least he believed not. The Directors had always followed the principle of keeping the capital down, satisfied if they could pay a fair dividend and keep a strong reserve. The other honourable proprietors who had written to the Board were of opinion that they ought to pay a larger bonus, and they said what they were very conscious of, that the sum carried to reserve is large in proportion to the dividend. That was very true; but they had a property liable to attack, and which was being attacked at the present moment, and in a manner which seemed to leave no alternative short of a war of tariffs. It looked like that at the present moment, but a great deal might happen between just now and by and by. They were warned by their rival on the west coast that if they did something—which this Company certainly would do, and must do—they would reduce the rates; but they were not without resources to meet that threat, if it were to be put into practice. That rival, so far, lowered the tariff, and so had they. On a previous occasion he told them they had reduced their tariff by 33 per cent. and 50 per cent., and they could go as low as any company could, and not be altogether without a dividend. He thought he told them at their last meeting who their rival was. He had a cable from Panama to Valparaiso. A few years ago their Company worked in harmony with a company called the West Coast of America Company, going from Lima and Callao to Iquique, Arica, and those ports down to Valparaiso. For some reason not known to them yet, that gentleman disregarded his partners, and carried his cable down to Valparaiso, leaving the west coast cable out in the cold. It so happened that the Globe Company was largely interested in that cable, and they did not see—and do not yet see—why that cable should be ruined, and they did not intend that it should be. In order to protect that cable a company had been formed to lay a land line across the Andes from Valparaiso to connect the west coast of America cable with the east coast cables, so they would have in a few months' time cable communication all the way from London to Lima from Peru to England and Europe; and their friend threatened them, as he understood, that if they did not let it alone he would do something very dreadful, and come and attack them, as he had done for years. They were making that line, however, across the Andes. It was three parts made already, and, do what he would, they would fight for it, and they would then see what happened. Then there was the company on the east coast from Senegambia to Pernambuco. That cable had been making for the last two years, and now opened, or about to be opened, for traffic. The promoters sought to raise money by the avowed and published statement that they would take £80,000 per annum from that company or the joint purse companies, and they opened their cable at a tariff 6d. per word lower than the tariff agreed upon—as fixed on by the Paris Conference as the obligatory tariff by every route for extra European traffic. He would explain that. The Telegraph Convention, which met every five years, had agreed that all traffics transiting any part of Europe was certain traffic, and that no company should come in and have a lower tariff, the object of the convention being to create as many ways as possible for telegraphic communication at equal rates—not opposition rates. That was called the European *régime*. For extra European traffic there was a higher tariff charged over the land lines transiting Europe, because they very properly said, "If we have to maintain land lines all through Europe, Russia, Italy, and those great distances—if we have to maintain them for extra European traffic—necessarily, as there is nothing else going over those lines, we must have a larger tariff." There was, therefore, a European *régime* and an extra European *régime*, and the convention said that those two tariffs should be common to all comers; but no one was to come in and oppose them with European powers by some accidental line got up for [illegible] purposes. Therefore they were leagued together at this conference to establish a tariff fair to all comers. It seemed strange to [illegible] that a private company, in disregard of inflicting loss upon every European State, and upon the cable companies more especially, should, without any attempt to negotiate, rush before the public with a reduced tariff, for no reason in the world but to force them to make terms that would give a value to their property which it did not now possess, as it is, so to say, a fifth wheel to a coach. Now he did not wish to say even so much about the case, but it was due to them that he should say something about a rival that had just come into the field. Its promoters, who are also its proprietors, were not allowed to carry their traffic lower than the convention rates; but they were, he was told, carrying Press traffic free—or they were doing so two days ago. They were, as they said, determined to worry them into terms which they hoped would enhance the value of their speculative cable. They pretended friendliness, and, personally, they were all friends; but they left no stone unturned to injure them, and it was possible they might tire of carrying even Press messages for nothing. At all events, it did not frighten them. Then there was the Antilles cable, which was owned by a French company, and which went from Guadeloupe down to Para. They hoped to get a concession from Portugal to go to the Azores. That was given to their Company, but from some [illegible] diplomatic action it was taken from them. As he had said, that French company were now trying to obtain from France a subsidy of £80,000, and if they could get that they proposed to carry the [illegible] and join it on to the Antilles cable. He did not know that [illegible] was very much inclined to pay that £80,000, and, at all events, they had not got it yet. They would observe from what he had said that it was a very costly fight that was now going on, but he ventured to believe that they would approve their policy of paying a moderate dividend and making a strong reserve, equal to a system of offence or defence. They were carrying messages from Buenos Ayres to England within the hour, and from Pernambuco to Rio Janeiro within the half hour. Commerce would not want greater facilities than that, unless it were that they should [illegible] telegrams free, and that they could not do. They were just now in a position as if a merchant in London had his foreign correspondent in the same building, and they carried on their intercommunication by what some [illegible] called a whispering gallery. There was no system of international telegraphy which could beat them. He did not know what science had in store for them; but, so far, they did not know that there was anything looming in the distance that could excel what they were now doing, and they could adopt anything that may be proved to be better and faster. Their cables were duplicating and duplexed, their speed of transmission could not be excelled, and they had a substantial reserve, which enabled them to look their rivals in the face, and they certainly need not be under any feeling of panic or alarm. That was the position they were in and, in his opinion, it was a sound one. They had laboured at it all along for 19 years steadily pursuing the policy of building up a reserve fund, and warning them from time to time that this was their backbone, and that while they were paying a good dividend they must be satisfied to let the Directors take from the revenue what they could spare to strengthen their position. The Chairman, in conclusion, said: "I look forward to this with our reserve fund, that if we were in a tight fight we could do two things—we could take the interest on the reserve fund and [illegible] to the reserve, and not add any more to that fund, or we could take it for increasing your dividend, plus any dividend arising from the traffic. I, therefore, do not address you in a [illegible] spirit or in a despairing tone. I think we are in a good [illegible] position. If any shareholder desires to ask any question, I will do my best to answer him; meantime I propose the adoption of the report and accounts, and the payment of the dividend and bonus recommended."

Mr Frederick Youle seconded the motion.

Dr Trowbelle, whilst supporting the Board in setting aside a good reserve fund, thought the Directors might take into consideration whether the amount transferred to that fund might be £10,000 or £20,000 a year less.

The **Chairman**, in reply, urged the proprietors not to press the Board on that subject at the present juncture, and pointed out that they were as much alive to the importance of the question raised as the shareholders.

The motion was then put and carried unanimously.

On the motion of the **Chairman**, Sir Henry Tyler, Bart., and the Duke de Loule, retiring directors, were re-elected.

The **Rev. N. Willis** proposed the reappointment of **Mr Henry Dever** and Mr. John Gane as auditors of the Company.

This was seconded by **Mr W. C. West** and carried.

The meeting closed with the usual vote of thanks to the Chairman and Directors, proposed by **Mr Griffiths** and seconded by **Dr. Trowbelle**, which was briefly acknowledged by the **Chairman**.

BOARD OF TRADE REPORT.

The following is a continuation of the appendix to the Board of Trade report as given in our last issue.—Ed. *E.E.*

PROVISIONAL ORDERS.

Title of Order.	To whom granted.	Revoked or repealed.
	1890.	
Metropolitan Electric Supply Co. (Paddington) Lighting Order, 1890.	Metropolitan Electric Supply Co., Ld.	—
North London Electric Supply Order, 1890.	House-to-House Electric Light Supply Co., Ld.	Revoked July 10 1891.
St. James's Electric Lighting Order, 1890.	St. James's and Pall Mall Electric Light Co., Ld.	—
Wandsworth District Electric Supply Order, 1890.	House-to-House Electric Light Supply Co., Ld.	Revoked Jan. 21, 1892.
Malvern Electric Lighting Order, 1890.	The Local Board.	—
Manchester Electric Lighting Order, 1890.	The Corporation.	—
Morecambe Electric Light and Power Order, 1890.	Messrs. Thomas Reginald Andrews and Thomas Preece.	—
Moss Side and Stretford Electric Lighting Order, 1890.	Manchester House-to-House Electricity Co., Ld.	—
Northampton Electric Lighting Order, 1890.	Northampton Electric Light and Power Co., Ld.	—
Nottingham Electric Lighting Order, 1890.	The Corporation.	—
Oldham Electric Lighting Order, 1890.	Do.	—
Oxford Electric Lighting Order, 1890.	Electric Installation and Maintenance Co., Ld	—
Plymouth Electric Lighting Order, 1890.	Devon and Cornwall Electricity Supply Co, Ld.	Revoked Nov. 24, 1891.
Portsmouth Electric Lighting Order, 1890.	The Corporation.	—
Preston Electric Lighting Order, 1890.	National Electric Supply Co., Ld.	Repealed by Preston Electric Lighting Order, 1891.
Preston and Fulwood Electric Lighting Order, 1890.	Lancashire and Cheshire House-to-House Electricity Co., Ld.	Revoked June 10, 1891.
Salford Electric Lighting Order, 1890	The Corporation.	—
Sevenoaks Electric Lighting Order, 1890.	The Electric Trust, Ld.	Revoked June 18, 1892.
Stafford Electric Lighting Order, 1890.	The Corporation.	—
Stockton-on-Tees Electric Lighting Order, 1890.	Do.	—
Tiverton Electric Lighting Order, 1890.	Do.	—
Tunstall Electric Lighting Order, 1890.	The Electric Trust, Ld.	Revoked June 18, 1892.
Walsall Electric Lighting Order, 1890.	The Corporation.	—
Wigan Electric Lighting Order, 1890.	Do.	—
Windsor Electric Supply Order, 1890.	Windsor and Eaton Electric Light Co., Ld.	—
Woking Electric Supply Company Order, 1890.	Woking Electric Supply Co., Ld.	—
Wolverhampton Electric Lighting Order, 1890.	The Corporation.	—
Worcester Electric Lighting Order, 1890.	Do.	—
Wrexham Electric Light and Power Order, 1890.	Wrexham and District Electric Supply Co., Ld.	—
York Electric Lighting Order, 1890.	The Corporation.	—
	1891.	
Acton Electric Lighting Order, 1891.	The Local Board.	—
Birmingham Electric Light and Power Order, 1891.	Birmingham Electric Supply Co., Ld.	—
Bishop's Stortford Electric Lighting Order, 1891.	Bishop's Stortford Electric Light and Steam Laundry Co., Ld.	—
Bolton Electric Lighting Order, 1891.	The Corporation.	—
Bromley (Kent) Electric Lighting Order, 1891.	The Local Board.	—
Canterbury Electric Lighting Order, 1891.	The Corporation.	—
Cardiff Electric Lighting Order, 1891.	Do.	—
Chiswick Electric Lighting Order, 1891.	The Local Board.	—
Coventry Electric Lighting Order, 1891.	The Corporation.	—
Croydon Corporation Electric Lighting Order, 1891.	Do.	—
Dewsbury Electric Lighting Order, 1891.	Do.	—
Ealing Electric Lighting Order, 1891.	The Local Board.	—
Edinburgh Corporation Electric Lighting Order, 1891.	The Corporation.	—
Exeter Electric Lighting Order, 1891.	Exeter Electric Light Co., Ld.	—
Hanley Electric Lighting Order, 1891.	The Corporation.	—
Harrogate Electric Lighting Order, 1891.	Do.	
Heckmondwike Electric Lighting Order, 1891.	The Local Board.	—
Hertford Electric Lighting Order, 1891.	The Corporation.	—
Ipswich Borough Electric Lighting Order, 1891.	Ipswich Electricity Supply Co., Ld.	—
Ipswich Electric Lighting Order, 1891.	Laurence, Scott, and Co., Ld.	Revoked Dec. 30, 1891.
Kidderminster Electric Lighting Order, 1891.	The Corporation.	—
Killarney Electric Lighting Order, 1891.	Charles Edward Leahy.	—
Kingston-upon-Thames Electric Lighting Order, 1891.	The Corporation.	—
Leeds Electric Supply Order, 1891.	Yorkshire House-to-House Electricity Co., Ld.	—
Liverpool Electric Lighting Order, 1891.	Liverpool Electric Supply Co., Ld.	—
Llanelly Electric Lighting Order, 1891.	The Local Board.	—
Camberwell Electric Lighting Order, 1891.	Camberwell and Islington Electric Light and Power Supply, Ld.	—
City of London Electric Lighting (Brush) Order, 1891.	Brush Electrical Engineering Co., Ld.	—
Clerkenwell Electric Lighting Order, 1891.	Do.	*
Islington Electric Lighting Order, 1891.	Camberwell and Islington Electric Light and Power Supply, Ld.	—
St. Luke, Chelsea, Electric Lighting Order, 1891.	New Cadogan and Belgrave Electric Supply Co., Ld.	—
St. Luke, Middlesex, Electric Lighting Order, 1891	Brush Electrical Engineering Co., Ld.	†
Southwark Electric Lighting Order, 1891.	Do.	—
Wandsworth District Electric Lighting Order, 1891.	Stamford Hill, Tottenham, and Edmonton Electric Light and Power Supply, Ld.	—

* The County of London (North) Electric Lighting Order, 1892, scheduled to the Electric Lighting Orders Confirmation (No. 5) Bill, now before Parliament, contains a provision for the repeal of this order.

† The County of London (North) Electric Lighting Order, 1892, scheduled to the Electric Lighting Orders Confirmation (No. 5) Bill, now before Parliament, contains a provision for the repeal of this order.

Title of Order.	To whom granted.	Revoked or repealed
Westminster Electric Lighting Order, 1891.	Westminster Electric Supply Corporation, Ld.	—
Woolwich Electric Lighting Order, 1891	Woolwich District Electric Light Co., Ld.	—
Londonderry Electric Lighting Order, 1891	The Corporation.	—
Newcastle upon Tyne Electric Lighting Order, 1891	Newcastle and District Electric Lighting Co., Ld.	—
Newport (Mon.) Electric Lighting Order, 1891.	The Corporation.	—
Norwich Electric Lighting Order, 1891	Norwich Electricity Co., Ld.	—

Whitehaven Electric Lighting Order, 1891	The Town and Harbour Trustees	—
Withington District Electric Supply Order, 1891.	Manchester House to House Electricity Co., Ld	Revoked May 13, 1892.

BUSINESS NOTES.

York.—The York tenders are to be sent in by November 21.

Belgium.—Tenders are invited for the lighting of the streets of Athus, a town in Belgium.

Boscombe.—The electric light was used for the first time in the Boscombe Arcade on Friday evening last.

Glasgow.—Messrs. R. Tullis and Co. have introduced the electric light into their works at Rothes Bleachfield.

Electric Railway at Havre.—A concession is in negotiation for an electric railway connecting Havre, Harfleur, and Montivilliers.

Electric Crane.—The electric crane for the Manchester central station is being designed and manufactured by Messrs. Mather and Platt.

Berlin.—The Berlin Electrical Works Company, which runs the large central stations in Berlin, has declared a dividend of 7½ per cent. for the last financial year.

Glasgow Cables.—The contract for the supply of arc light cables for the Glasgow Corporation has been placed with W. T. Henley's Telegraph Works Company, Limited.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £3,611.

West India and Panama Telegraph Company.—The receipts for the half month ended October 15 were £2,470, against £1,402. The June receipts, estimated at £4,825, realised £4,757.

Siemens and Halske.—The American Siemens and Halske Company have begun well with a contract for 17,000 lamps at the Chicago Auditorium, the largest private installation in the country.

Borough-road Polytechnic.—The full number of members—2,500—have already joined this polytechnic. Workshops for engineering and electrical work are to be eventually added at a cost of £4,000.

Wolverhampton.—At the last meeting of the Town Council, on the proposition of Alderman W. J. Jones, it was decided to purchase a quantity of land in Commercial-road as a site for an electrical generating station.

South Africa.—The Moodie's Company, says the *Financial News*, has commenced extensive operations in connection with the electrical transmission of power. Electricity, it is predicted, will do wonders for the mines in the district.

Southport.—At the final meeting of the Southport Town Council for the municipal year, Councillor Watson reported that the Electric Lighting Committee were making good progress, and that they would shortly be advertising for tenders.

Callender's Company.—The Directors of Callender's Bitumen, Telegraph, and Waterproof Company, Limited, have declared an interim dividend at the rate of 8 per cent. per annum on the capital of the Company, payable on November 1 next.

St. James's and Pall Mall Company.—The electric current sold by the St. James's and Pall Mall Electric Light Company, Limited, for the quarter ended September 30 amounted to £5,763, as against £5,279 for the corresponding period of last year.

City and South London Railway Company.—The receipts for the week ending October 16 were £90[illegible], against £794 for the same period last year, or an increase of £108. The total receipts for 1892 show an increase of £1,108 over those for the corresponding period of 1891.

Wolverhampton.—At the meeting of the Wolverhampton Town Council last week, the report of the Public Works Committee was adopted, recommending the purchase of land adjoining the canal in Commercial-road for an electric lighting station, and also the erection of a refuse destructor.

Cardiff.—At the meeting of the Cardiff Electrical Committee on Tuesday, plans prepared by Mr. Massey, electrical engineer to the Corporation, of the proposed new electrical works on the Canton Common, adjoining the Great Western Railway, were submitted to the committee and approved.

Aberystwith.—During the last 10 days a portion of the promenade at Aberystwith has been illuminated by two large arc lamps, an experiment by the Town Council, who are very likely to go in for a scheme for the complete lighting of the town by electricity. A provisional order was obtained by the Council some months ago.

Blackpool.—In our note last week on the proposed use of dynamos at Blackpool, it was stated that the same dynamos would be used for both tramways and arc lamps. This is obviously an error. What is intended is to work the tram lines and the [illegible] and private lighting from the same station, though not, of course, by the same dynamos.

Mill Lighting.—An interesting event took place on Tuesday night at the quiet village of Dunshalt, situated between Ladybank and Auchtermuchty. The one factory there, belonging to Messrs. Wilson and Hill, of Ladybank, was for the first time illuminated with electric light. For some time back the gas light has been both poor and expensive.

Fleetwood.—The time for receiving reports upon electric lighting for Fleetwood has been extended, at the request of two competing firms. When the reports are completed a special meeting of the Highway and Lighting Committee of the Fleetwood Commissioners will be called to consider them. The 22nd [illegible] the date named for completion of reports.

Belfast.—At a meeting of the Belfast Council in committee on Saturday a report was presented recommending an electric installation capable of supplying 10,000 incandescent lights, and for future extension if found desirable and that the services of an expert electrician should be obtained to advise as to the best system, and the best method of procedure.

Marseilles Cables.—The submarine cable from Marseilles to Oran has been laid, and has been working for over a month with satisfaction. The contract was entrusted to the Société [illegible] des Téléphones. The Tunis cable, of which the contract was given to M. Grammont, is not yet ready. The Oran cable is the first French cable carried out without foreign help.

Carnaby-street Station.—Our readers will be interested to learn that the St. James's and Pall Mall Company have [illegible] against their policy of exclusion of storage batteries, at any rate for their new station, and that a contract for the storage [illegible] has been secured by the Electrical Power Storage Company for the St. James's and Pall Mall Company's new station at Carnaby-street.

Cardiff.—At the last meeting of the Council, Mr. Lewis moved that the site set apart on the Canton Common for the electric light station should be appropriated for a cattle market. Mr. T. J. Bevan said he would do all that he could to stop either the electric light station or market being placed there, but after discussion, on the understanding that the Electric Lighting Committee would make some arrangements for sidings, the resolution was withdrawn.

Bolton.—The Bolton Corporation have recently been investigating the question of electric lighting, and it has now been decided that the town shall be supplied with the electric light. The system adopted is to be also capable of running the [illegible]

which will probably be taken over by the Corporation at the expiration of the lease next year. The capital at present sunk in the gas undertaking is over £600,000, and the profits last year were £18,000.

Bridgend — At a special meeting of the Bridgend Local Board it was decided to obtain the advice of a consulting engineer on the general scheme proposed by the Local Board, which was the outcome of their recent visits to Linton and elsewhere. Finally, Mr. Morgan Williams, of the firm of Messrs. Morgan Williams and King, was instructed to advise them in the matter. The scheme includes the use of water power to supply a portion of the requisite energy.

Birmingham. The General Purposes Committee of the Birmingham Town Council held a lengthened sitting on Monday to discuss the notice by the Electric Supply Company of their intention to apply for an additional order extending their area. The consideration of the order was postponed for 12 months. At a later stage the committee will consider whether or not they will recommend the Council to promote an order for electric lighting on behalf of the Corporation.

Chiswick. At the meeting of the Local Board, the clerk in his report stated that he had received a communication from Sir Thomas Bloomfield, of the Board of Trade, to the effect that that Board would lose no time in considering the contract of Messrs. Bourne and Grant for the provision of electric light at Chiswick. In the discussion it was pointed out that the Board of Trade had had the contract under consideration since July, and it was felt that some effort should be made to urge on the matter.

Birmingham. B. Verity and Sons, owing to the growth of their electrical engineering business in the Birmingham district, have recently taken large offices at 116, New-street, Birmingham, above the showrooms where their goods are exhibited. Their branch showrooms at Manchester, it may be mentioned, are 20, Princess-street, facing the Town Hall. All matters connected with their "Electrical Compendium," or with goods dealt in by the firm, are carried out solely by the works department at Aston, Birmingham.

Hammersmith. —The following streets were scheduled as the area to be electrically lighted in the Hammersmith district: King-street, from Broadway to Ravenscourt-park; Broadway; Hammersmith-road, from Broadway to St. Paul's School; Queen-street, from Broadway to further side of St. Paul's Church; Brook-green-road; Shepherd's Bush-road; across Shepherd's Bush-green to corner of Wood-lane. There were also added the Goldhawk-road to Starch Green Pond, and Uxbridge-road to the corner of Percy-road.

Edinburgh. — There is at last a prospect of Edinburgh following the example of the West in the matter of lighting common stairs, as a sub-committee of the Town Council have resolved to recommend that a clause should be introduced in the new Municipal Bill providing that the gas in all common stairs in the city shall be lighted and extinguished by the servants of the Corporation. The matter will be on a much more satisfactory footing, however, if electric light was used for this purpose, as the attention required by gas will be considerable.

Glasgow Tramways. —The *Glasgow Herald* continues its able articles on the "Tramway Motor Question for Glasgow," and in its article of last Friday gives, besides statistics of the Thomson-Houston and Siemens systems, a long account of the closed circuit system of Mr. Carl T. Brain, of Liverpool, whose system was recently described by us. The *Herald* comes to the conclusion that the Brain system will be more costly than a cable system for very crowded traffic, but that it would probably be useful where there is a fair traffic, though not enough to make a cable line pay.

Forest Gate. —A meeting of the Forest Gate Ratepayers' Association was held last week, Mr. Saward, deputy-chairman, presided. Mr. Sharp said he had written to the town clerk, and asked if the Town Council would permit a company to run electric light in any portion of the borough. The town clerk had replied that the Council had now obtained a provisional order empowering them to supply the electric light, and the matter would come before the Works Committee. It was agreed to defer consideration of the subject until it was known what the Town Council would propose to do.

Newbury. At the meeting of the Newbury Town Council last week, the Mayor formally moved that the cost of obtaining the electric provisional lighting order, and of the Act confirming the same, be taxed, and that it be referred to the Gas Committee to report and advise as to further proceeding of the Council in connection with the said order. Mr. Long seconded the proposition. The town clerk produced a printed copy of the Act, and in reply to a question, said he could not tell the exact costs that had been incurred in connection with this matter, but thought they would probably amount to about £300. Mr. Smith said that the sum mentioned as the probable cost of the Act when the subject was first mooted was £40. The motion was then adopted.

Windsor. —The Windsor and Eton Electric Light Company, which has been nearly four years in process of formation, has at last found itself in a position to start upon a practical scheme of operations. Matters having been arranged with the Board of Trade, the statutory notice has been served of the intention to proceed at once with the opening of streets for the purpose of laying the mains to supply the electric light, and before the end of the year it is hoped that the company's service will be available in Thames-street, High-street, and Peascod-street. The extension of time thus secured for laying the cables preserves to the company the monopoly of electric lighting in the extended area for which their provisional order was originally obtained.

Queensferry. —Some time ago the Town Council of Queensferry, Scotland, had under consideration the propriety of purchasing the gas works within the burgh, presently owned by a private company. Owing, however, to the difficulty of manufacturing gas in Queensferry at anything like a reasonable price, it was deemed advisable to make enquiries regarding other means of lighting before proceeding further in their negotiations with the gas company. Having at their command considerable water power, the Corporation are of opinion that the electric light might be introduced at almost as cheap a rate as gas; consequently, at the last meeting of the Town Council the matter was remitted to a committee, with power to employ an expert with the view of ascertaining the probable cost of such a scheme.

Queen Victoria-street Subway. The Highways Committee of the London County Council report that they have considered an application from the General Post Office for permission to place an additional four-wire cable in the Queen Victoria-street subway, between Queen-street and the Savings Bank. They are advised that there is no objection to the granting of the permission now applied for; and recommend that, subject to the provisions of the agreement between the Postmaster-General and the Council with reference to the use of the Council's subways, permission be given to the placing by the Post Office Telegraph Department of a four-wire cable in the Queen Victoria-street subway between the points mentioned in the application. They also reported various notices under Electric Lighting Acts and Orders for house connections.

Electric Tramway to Barry Island. We have it on trustworthy authority, says the *Barry Dock News*, that plans have been prepared, and the directors of the Barry Railway Company are perfecting a scheme, for the construction of an electric tramway from a point near the railway bridge at the East Barry end of the dock to Barry Island. The proprietors of Barry Island, with its charming Whitmore Bay, are determined to render it a most attractive seaside resort, and in this direction the Barry directors are prepared to lend all the assistance in their power. Already the company have anticipated the development which must take place in this respect upon the island, and the curves of the bridges have been so constructed as to admit of the formation of a tramway as proposed, and the actual laying of the rails was only deferred last year on the ground that they could be laid without any trouble when required. It is expected the electric tramway will be ready for the next summer season.

Elgin. The first installation of electric light in Elgin has recently been put into the premises of Mr. Gordon S. Shiach, L.D.S., of North Guildry-street. For some time he has used electricity in his profession, and now has installed the light throughout his house. He has a separate engine room with a Campbell gas engine, driving a dynamo at 1,900 revolutions, on the Scott-Sisling system. Two tiers of storage cells are used of the Crompton-Howell pattern. The dining room and drawing-room are lighted with two 16 c.p. lamps each, and both 8 c.p. and 16 c.p. lamps are used elsewhere. Major Grant, of Glengrant, it may be mentioned, was the first to introduce the electric light into Moray. Now that Mr. Shiach, by his enterprise, has led the way in Elgin, it is thought that in a very short time several other householders in Elgin will follow his example. The day, perhaps, may not be far distant when those who dwell near such streams as the Lossie will take advantage of the water power to drive electric machinery. We have already mentioned that the system adopted is the Scott-Sisling system of lighting, for which Messrs. R. H. Barnett and Co., Newcastle-on-Tyne, are agents for the Northern counties. The installation at North Guildry-street has been carried out by Mr. G. W. Lammis Pattison, electrician to Messrs. Barnett and Co., with complete satisfaction.

Heckmondwike. At the meeting last week of the Heckmondwike Town Council, the newly formed Electric Light Committee reported that they had held a meeting, when Mr. Wood was appointed its chairman. It was resolved that the clerk get out all the correspondence relating to the electric lighting and other companies who are prepared to contract with the Board for the lighting of the district with electricity at their own cost, and that the same be deposited for inspection by the members of the Board for the next seven days. A letter referred from the last Board meeting was read from Mr. J. H. Firth respecting electric lighting, and the clerk was instructed to acknowledge the receipt of the letter, and to inform Mr. Firth that the matter is still under discussion. A letter dated the 9th inst. was read from the Gulcher (New) Electric Lighting Company with respect to the lighting, and it was resolved that the letter be placed amongst the other letters for the inspection of this committee; that the clerk write to the Co-operative Wholesale Society, and to Messrs. J. F. Firth and Sons, Limited, asking how many electric lights they would require if the Board were prepared to supply the same at 6d. per Board of Trade unit. These minutes were confirmed. Mr. Albert Rhodes apologised to the chairman and members for having used an unparliamentary expression at the last meeting in the excitement of the discussion on the electric lighting question.

Windermere. —At the monthly meeting of the Windermere Local Board, last week, the Chairman, referring to the application for electric lighting made at last Board, as mentioned in the minutes, said the question would come before the next meeting of the committee of the County Council, and he supposed the Board would do nothing further than they had already done. Personally, he did not wish to enter on the question, as he was chairman of the gas company, but he considered the Board need not do anything to obstruct the scheme. Mr. Irving wished to know whether, providing the Board obtained an order from the Board of Trade, they could not then take over the plant after a certain time. The clerk replied that there was a difference between a

provisional order and a mere license for the purpose, but he was not sufficiently acquainted with the matter to go into details just then; besides, there was a very recent Act relating to the subject, but he thought if Mr. Fowkes's company got a provisional order the Board would not have an opportunity of taking it at less than 40 years, but if only under a license, they might acquire it at the end of seven years. Mr. Irving asked whether, supposing permission was given to lay the cable, and it proved a failure, they would be entitled to break up the roads again for the purpose of taking it up. The clerk did not know, but thought it would scarcely be worth the trouble. At any rate, they would require leave from the local authority before putting it down. The matter was eventually left as before.

Telegraph Convention between Russia and China.—A new telegraph convention between Russia and China has been signed at Pekin by the Russian Minister and the head of the Chinese telegraph administration, and now only awaits ratification by the respective Governments. Details have been brought by this week's mail. The points of junction are to be Hunchum Possiette, Holampo Blagoveschensk, and Kiachta, the first of these three to be made immediately after ratification of the treaty, the second as soon as the cable across the Amour is laid, and the third when the line from Pekin to Kiachta is constructed. It is provided that each country shall be responsible for the maintenance of the lines within its own borders, that the cable across the Amour is to be laid at the joint expense of both and to be the property of both. They agree to be bound by the rules of the Telegraphic Union, to send State messages free, to maintain the same tariff without alteration, save by common consent; and to reduce the rates if outside competition should seem to require it. The treaty is to last until December 31, 1892. By this arrangement messages between China and Asiatic Russia cost only 3.73f., and between China and European Russia 4.73f., while the rest of Europe will pay 8.50f. The treaty, it must be remembered, has still to get the ratification of the Chinese Government. By the foreign mercantile communities in China it is regarded as hostile to their interests, for its effect will be to maintain the present very high rate for messages between China and Europe.

Harwich.—A great discussion took place at the last meeting of the Harwich Town Council on the cost of obtaining the provisional order, the bill for which was £337. Mr. Rose said he should vote against it, as the town clerk had said that it would be about £150. Mr. Hill expressed surprise that Mr. Rose should vote against the bill when it was he who had been so anxious to promote electric lighting, having given his sanction when nine-tenths of the inhabitants were opposed to it. The clerk explained that the bill was that of the parliamentary agents, his own charges being put down at 10 guineas, and included several visits to London. He pointed out that the bill was entirely provided for in the estimate to be presented that day, and a 1s. rate would be sufficient. The Mayor observed that the bill fell upon them all with surprise, and upon no one more than himself and the town clerk, who, he was sure, was very much upset about it. He considered that Mr. Ward had acted very liberally, considering all the circumstances of the case. He could have sent in a bill of his own for some £40, but instead of that refused to charge except for actual expenses. The bill was passed, but subsequently Mr. Hill gave notice that at the next meeting of the Council he should move a vote of censure on those members who, knowing the wishes of nine-tenths of the ratepayers, ignored their memorial, and voted away £337 for the provisional order. Mr. Everard caused amusement by giving notice that he should also move a vote of censure on those members of the Council who promoted the opposition to the electric lighting order, and so increased the cost.

PROVISIONAL PATENTS, 1892.

OCTOBER 10.

18025. **Improvements in and relating to electric elevators.** Alonzo Bertram See and Walter Lincoln Tyler, 70, Market street, Manchester. Date applied for under Patents Act, 1883, Sec. 103, March 14, 1892, being date of application in United States.) (Complete specification.)

18037. **Improvements in electric welding apparatus.** William Charles Mountain, 3, St. Nicholas buildings, Newcastle-on-Tyne.

18039. **Improvements in electrolytic cells and diaphragms.** James Hargreaves and Thomas Bird, 4, Clayton square, Liverpool.

18066. **Improvements in electric meters.** Frederick William Golby, 36, Chancery lane, London. (Jules Adrien Djardin France.)

18077. **Improvements in electric switches.** Henry Thomas Paiste, 321, High Holborn, London. (Complete specification.)

OCTOBER 11.

18116. **Improvements in and relating to electric arc lamps.** Wilhelm Mathiesen, 70, Market street, Manchester. (Complete specification.)

[illegible]. **Improved electrical arrangement or device for the control of workmen's time checks.** Henry Davis, 52, Chancery lane, London.

[illegible]. **Improvements in and relating to conduits for electric railways.** Robert Booth, 17, Sarsfeld road, Balham, Surrey.

18154. **Improvements in electric arc lamps.** Robert Drysdale, 141, Upper Mary street, Balsall Heath, Birmingham.

18160. **Improvements in telephonic receivers.** James Philip Annett, 2, Great George street, Westminster, London.

NOTES.

Tyrol.—An electric railway 27 miles long, between Riva and Pinzolo, in the Tyrol, is projected.

Technical School.—The Spring Gardens mill at Bacup is being fitted up as a technical school.

Russian Telephones.—It is stated that the Russian Government intends to buy up the telephone lines in its dominion.

Asnieres.—The central electric station at Asnières, France, has been completely destroyed by fire, the damage being 80,000f.

Budapest.—The firm of Ganz and Co., of Budapest, have recently added to their already large works an electro chemical laboratory.

Electro-Harmonic.—The smoking concert of the Electro-Harmonic Society will take place to-night (Friday) at St. James's Hall Banqueting-room.

Aluminium.—According to M. Mannesmann, a little tungsten added to pure aluminium obviates all difficulty from attack by water, salt water or otherwise.

Electrical Manufacture of Chemicals.—A great fuss is being made in certain quarters about the direct manufacture of chemicals from brine by electricity. As yet we have not much faith in this discovery.

Junior Engineering Society.—The inaugural meeting of the session of this society will be held on Friday, November 4, at 8 p.m., at the Westminster Palace Hotel. The presidential address will be given by Dr. John Hopkinson, F.R.S.

Sherborne.—An exhibition installation is on view at Sherborne, containing wind engines for electric light, policemen's lamps, gas and petroleum engines, and so forth, and there is room for other exhibits if anyone is desirous of showing goods.

Raguse.—A central station has just been started in the town of Raguse. Water power is supplied by two turbines of 100 h.p. The whole of the electric part of the installation has been carried out by MM. Brown, Boveri, et Cie., of Baden, Switzerland.

Electric Sewing Machines. — A large costume establishment of Paris is being fitted by M. Jaques Uhlmann with electrically-driven sewing machines. The current, at 110 volts, is taken from the street mains, and each motor takes two amperes.

Camberwell.—The Camberwell Vestry have set a good example by giving the necessary power to the General Purposes Committee to secure the services of a gentleman to lecture at the Vestry Hall on "How to Light Camberwell by Electricity." The name of the lecturer has not transpired.

Taxation of Machinery.—A mill in Sunderland was assessed recently at £450 increase. On appeal, the assessment, instead of being increased, was decreased by £400. This case should encourage manufacturers to resist unfair assessments. The case was in the hands of Mr. G. Humphrey Davies, surveyor to the Associated Manufacturers.

Wimshurst Machine.—The Wimshurst induction machines have a strange fascination for experimentalists, and many electricians are doing their best to lead the wayward high-tension spark to a useful purpose in lighting or other application. Sir Archibald Campbell has, we are told, an 80-plate machine driven by a motor for experimental work.

Luxurious Train.—Messrs. Brown, Marshall, and Co., of Saltley, have just built a most luxurious train for the P. and O. service, to run between Calais and Brindisi, fitted with every requisite that comfort can suggest. Electric bells are used throughout, and we suppose small sets of storage electric lamps will also be used, though this is not stated.

Electric Railway in Hungary.—A large scheme is promulgated by Messrs. Ganz and Co. for the construction of an electric railway between Vienna and Budapest. The first project submitted to M. Baros, the Hungarian Minister of Commerce, has been refused approval, but other plans are being prepared, and it is yet hoped the scheme may receive approval.

Household Lighting.—Books on house lighting by electricity are in the air. We have already noticed one recently published, and we are now informed that another will be issued shortly under the title of "Household Electric Lighting," by Mr. Angelo Fabie, M.I.E.E.; paper cover 1s. 6d., cloth 2s. 6d. Publishers: Spon and Co., London; J. Falconer, Dublin. The book will be fully illustrated.

Chicago Telephone.—The tests made with the Chicago-New York long-distance telephone line have not been entirely satisfactory, though sufficiently so to give promise that the difficulties will be overcome. The music of a cornet was distinctly transmitted, but speech less distinctly, though it was possible to communicate. The charge is 9dol., or 38s., for five minutes' conversation. It is not likely to be much used at this rate.

Medals.—At the meeting of the Institution of Engineers and Shipbuilders in Scotland the medals and premiums awarded at the annual general meeting of the institution, held in April, were presented. Among these were premiums of books awarded to Mr. Henry A. Mavor for his paper on "The Development of Electric Distribution;" to Prof. Andrew Jamieson, F.R.S.E., etc., for his paper on "The Electric Lighting of Public Buildings."

Telephonic Telegrams.—Dolyddelen, in Wales, has long yearned for telegraphic communication. It has hitherto received nothing but official notices on large sheets of blue paper of the necessity of a warranty of income. Now, however, posts are erected not for a telegraph line, but for telephones, and everybody is satisfied. The connection is to the charming resort of Bettws-y-Coed, loved of artists and tourists. If they stray to Dolyddelen, they are not now beyond reach of the outside world.

Liverpool University College.—The first excursion of the Walker Engineering Laboratory, Liverpool University College, took place last week to the Highfield-street central station of the Liverpool Electric Supply Company, by kind permission of Mr. A. M. Holmes, engineer to the company. The party (40 in number), accompanied by Prof. Hele Shaw, were conducted through the works by Mr. Holmes, who explained each department, including the boiler-house, accumulator-rooms, and dynamo, transformer, and engine rooms, explaining the methods of supply and testing.

Electricity in Mines.—In a leading article in the *Iron and Steel Trades Journal* it is pointed out that electric coal-cutters "would be much improved if adapted to drill in any direction besides the vertical without disturbing the horizontal position of the framework." After alluding to the benefits of electric locomotives for hauling, our contemporary remarks that there is a good field for electric railroads with overhead conductors for mining districts, "as the water power heretofore neglected is being called

into service and the transmission of power to distant points is becoming the necessity of the future."

Soleure.—The Compagnie de l'Industrie Electrique, of Geneva, has just been awarded the contract for the complete installation of a central electric station and mains necessary for the lighting and transmission of power for the town of Soleure. The central station will include two Thury continuous-current dynamos, driven by turbines and coupled in series, giving a pressure of 6,400 volts for transmitting 365 h.p. a distance of 28 kilometres (16½ miles). We hope to give full details of this interesting installation when it has started work.

Coast Communication in Kent.—With a view to advancing the interests of the seafaring community, and also to increasing the facilities for saving life at sea, electric communication has been greatly improved along the Kentish coast. Broadstairs, Ramsgate, and Margate are now telegraphically connected with Lloyd's signal station, North Foreland. The North Sandhead lightship, Goodwin Sands, will, it is now stated, be connected by cable with the station to be erected at Dumpton Gap, about half-way between Broadstairs and Ramsgate. At this station a man will be constantly on duty.

Colour Photography.—M. Lippmann has been pursuing with energy his investigations into colour photography. He says that "on the layers of albumino-bromide of silver rendered orthochromatic by azaline and cyanine, I obtained very brilliant photographs of spectra. All the colours came out at once, even the red, without the interposition of coloured screens, and after an exposure of from five to thirty seconds." He submitted photographs of stained-glass windows, draperies, oranges, and a parrot, taken by electric light with five to ten minutes' exposure, in which the colour is noticeable as well as the form.

Edison Lamps.—It is understood that the General Electric Company has no intention of attempting to squash the other American lamp manufacturers, nor take steps to raise the price. Licenses will probably be issued to manufacturers at a reasonable royalty. The present plant of the General Electric Company would not be sufficient to cope with the monopoly, nor would it probably be wise to increase the factory for the short time the patent has yet to run. The Westinghouse Company are intending to take up immediately the manufacture of a new type of lamp which it is claimed does not infringe upon the Edison patent.

Decimal System.—The New Decimal Association has recently issued a new prospectus, which shows that the general committee consists of 14 members of the House of Lords, principal among whom on the science side is Lord Kelvin, 27 members of Parliament, representatives of 37 Chambers of Commerce, 27 Trades Councils, and numbers of bankers, engineers, electricians, and merchants. It is expected that the day is not far distant when the decimal system will be taught alongside the other in every Board school, and when this is done the extension of the knowledge of the system to the public will be a matter of a few years only.

Multiphase System.—The *Electrical World* learns that in New England a plant is to be installed this month, using a multiphase generator and motor, each of 300 h.p. capacity, to transmit power from a waterfall 11½ miles distance. The motor will be used to drive dynamos, to supply the current for street lighting. We should have thought transformers would have been simpler. Electric tramway considerations may be in view, for our contemporary adds, "Such service would be an ideal one for driving railway generators, owing to the steadiness of running and the fact that violent fluctuations of load that are such a prominent feature of railway operation produce an inappreciable effect on the speed of multiphase motors."

Messrs. Whittaker and Co. announce Prof. Oliver Lodge's "Treatise on Lightning Conductors and Lightning Guards"; "A Comprehensive Work on the Dynamo," by C. C. Hawkins and F. Wallis; "The Principles of Fitting for Engineer Students and others"; "Electrical Experiments," by G. E. Bonney; "Practical Electric Light Fitting," by F. C. Allsop; "Electric Lighting and Power Distribution," by W. Perren Maycock, M.I.E.E.; "How to Manage a Dynamo," by S. R. Bottone; "Electricity and Magnetism," by S. R. Bottone; "Chemistry," by T. Bolas, F.I.C., F.C.S.; "Geology," by A. J. Jukes Browne, F.G.S.; and other volumes.

American Storage Battery Monopoly.—After a struggle lasting for about ten years, beginning in the Patent Office and carried successively through the United States Circuit Courts in several states, the United States Circuit Court of Appeals, on the 4th inst., handed down a decision sustaining the decree of Judge Coxe rendered in July, 1891, in the suit of the Brush Company against the Electrical Accumulator Company. The sole right to use storage batteries with the active matter mechanically applied is now owned by the Consolidated Electric Storage Company, the licensees of the Brush Electric Company. Consequently, says the *Scientific American*, this decision gives to the Consolidated Electric Storage Company a monopoly of the storage battery business throughout the United States for a period of over 10 years next ensuing.

Glasgow Omnibus.—It seems that the Glasgow Tramway Company, ready with improvements, started an omnibus on Saturday, not only electrically lighted but furnished with pneumatic tyres. The omnibus moves with the greatest smoothness and noiselessness. The seats inside, which are covered with crimson velvet, are mounted on springs, which adds much to the comfort. The electric lamp is fixed in the roof, supplied from a battery underneath one of the seats containing a sufficient storage of electrical energy for 24 hours. Twelve passengers can be carried inside and 14 outside. The tyres on the wheels measure about 3½in. in diameter, and can withstand a pressure of 187lb to the square inch. To guard against any risk of the indiarubber being punctured by sharp stones or otherwise the tyres are thoroughly protected by several plies of canvas, together with a covering of wire wove netting. The improved 'bus is much appreciated.

Electro-Therapeutics.—Our contemporary the *Western Electrician* has a note commending the action of the London *Electrical Review* in its creditable work of exposing quackery. We are in accord with our contemporaries and would point out that technical journals are oftimes placed in a pecuniary loss by their action concerning "quackery." It is by no means uncommon to receive copy for an advertisement at a high price from advertising agents of good standing. Greatly to the credit of what may be termed the representative technical journals of this country, all such advertisements are instantly refused. There is no doubt that either the *Electrical Review* or ourselves could benefit to the tune possibly of hundreds of pounds were the restrictions concerning such advertisements withdrawn. When, then, a technical journal abandons its silence and undertakes, in self-defence, an aggressive policy, it is the interest of its colleagues and the industry generally to support the good work.

Electric Fountain at Craig-y-Nos.—M. Gustave Trouvé has just finished a commission for an electric fountain at Craig-y-Nos, the Welsh mountain home of Madame Patti-Nicolini. The basin of the fountain is 20ft. diameter

and the jets are illuminated by four 200-c.p. incandescent lamps. The light is projected on the jets by means of four parabolic reflectors under the glass-covered chambers, from which the water springs. The tints are given to the light by interposing coloured glasses arranged on two superposed discs, concentric or otherwise, which are turned in the same or opposite directions with equal or unequal velocities by means of a small waterwheel. By this means the play of colour on the water can be diversified like that of the kaleidoscope. Each of the lamps consume six amperes at 110 volts. Mr. Trouvé was assisted in carrying out this electric fountain by Mr. Surridge. There is also a brilliant search-light on the tower at Craig-y-Nos, which is brilliant enough to be seen 14 miles away. Craig-y-Nos has now the right to be called a veritable electrical palace.

Gearless Motors.—An improved gearless motor has been brought out by the Short Electric Railway Company in America. The chief points of this new motor, of which great things are expected for heavy work, are that it weighs 2,300lb. for 20 to 25 h.p. motors, and is capable of being coupled direct to 30in. wheels. It is triangular in shape, and has 13 field magnets cast integrally with the frame, and three consequent pole-pieces, making a six-pole machine of peculiar form. The frame is of cast steel, and every part is utilised in the magnetic circuit. It is waterproof, has only two brushes (carbon). The copper capacity is very large. Friction and hysteresis are reduced to a minimum, and its efficiency reaches nearly 90 per cent. at one part of its load. Two motors are intended to be used on each car, and in series will make 10 miles an hour, and in parallel about 20 miles an hour. The motors are made about 20 h.p. for the ordinary street railroads, but will be made of larger size for interurban traffic. The motor is to be shown and tested at the National Street Railway Convention at Cleveland.

Electrical Coast Communication.—The resolution of the House of Commons passed last session, on the motion of Sir Edward Birkbeck, Bart., on behalf of the Royal National Lifeboat Institution, relative to the establishment of a complete system of electrical communication on our coasts, has already produced good results, many of the coastguard stations and post offices on the most dangerous parts of the coast having already been telephonically or telegraphically connected with the view of giving early notice to the lifeboats that their services are required. During the recent storm there were no less than three instances in which the newly-established telephone wires proved of service. At Brancaster the lifeboat was called out by a telephone message from the coastguard at Thornham and saved five lives. At Hunstanton the lifeboat crew were promptly assembled in response to a telephonic message, but the necessary assistance was given by another boat; while at Wenterton the telephone was successfully used to secure the services of a tug from Yarmouth to tow out the lifeboat to assist a wreck on the Happisburgh Sands.

Ozone.—The commercial manufacture of ozone, which was carried on in London by Mr. Ernest Fahrig a year or two ago, has been undertaken by him on a more extended scale in Marseilles, Illinois. The Fahrig process consists in the manufacture of oxygen from peroxide of manganese and hydrate of soda and lime, and its ozonisation by electricity. The installation is established in connection with the American Ozonised Water Company, and is described in a recent number of the *Western Electrician*. Ozone is found a much stronger and far less harmful bleacher than chlorine, and is now used for the blanching of spices, treatment of table-water for killing the germs, preservation of tinned meats, fish, and milk, the ageing of wines, oxidation of oils, destruction of bad matters, bleaching of linen, silk, ivory, bones, sponges, and other materials. The ozone industry, under Mr. Fahrig's earnest and persevering endeavours, promises to become an important one, and is an example both of the usefulness of electricity and also of the utility in the present state of the electrical industry for an experimenter to take some specimen field of manufacture, create a demand, and himself fulfil this demand.

Accumulator Traction.—The notice issued recently by the Electrical Power Storage Company of their willingness to undertake accumulator traction at a fixed and not too large proportion of the total receipts, has aroused a considerable feeling of interest and even of surety that at last something may be done with the ugly duckling of British electrical engineering — tramcar traction. We hope the matter will speedily turn out successful, and, if so, there will be all the greater encouragement for inventors to deal with the lightening of the weight of the batteries. The enormous weight of three tons now carried, according to Mr. Dickenson, on the Birmingham trams, is evidently ridiculous. Attention is directed on the Continent, as will be seen by a note, to the lightening of weight, but the hints given in our last issue as the result of Mr. Desmond FitzGerald's experiments in gilding lead are, in our opinion, more likely than investigations in any other direction to prove a practical solution of the weight difficulty. Meanwhile, Mr. Frank King is convinced of the safety of his policy, and we understand that several very large projects are under consideration.

Nelson.—The works for the supply of Nelson (Lancs.) with electric light have been commenced. The station is for 600 16-c.p. lamps, and applications for over 300 lamps have been received. The dynamo will give 360 amperes at 110 volts. Of main cable 1,550 yards will be laid. The cable itself will be composed of 61 copper wires, forming almost a solid copper bar, covered with pure vulcanised indiarubber and coated with hemp and tar. The cable will be 1⅜in. in diameter. Cast-iron troughs in 6ft. lengths, each weighing 2¼cwt., will be used, and to prevent the admission of water, and thus preserve the insulation of the cable, the covers of the troughs will be packed with solid indiarubber, with also indiarubber packings between the troughs. Tapping-boxes will be placed at intervals. From the tapping-box the wires are conveyed in glass-lined wrought-iron tubes, 1¼in. in diameter, to small junction-boxes, very similar in construction to the tapping-boxes. From each of these boxes the current will be conveyed in two glass-lined tubes to the premises of consumers. The designing of the scheme has been carried out by Mr. John Foster, the assistant gas manager, and the establishment of the installation will be carried out under his supervision.

Boulogne-sur-Mer.—The central electric station of Boulogne is situated nearly outside the town, three-quarters of a mile from the centre of the town, close alongside its principal customer, the railway station. The distribution is carried on by the three-wire system and accumulators. Two Weyher and Richemond condensing engines of 125 h.p. drive two Desroziers dynamos of 250 amperes, and 300 to 350 volts, and a smaller dynamo of the same make giving 130 amperes at 120 volts. The latter charges the accumulators specially installed for the railway station, arranged in two groups of 92 cells, taking 130 amperes charging current, with their own switchboard. From the other dynamos mains are led to a sub-station of batteries of 130 cells, with an output of 400 amperes. A hand-regulator is used to vary the cells in charge and discharge, and by a special arrangement used here, it is believed, for the first time, the set of batteries can be connected up

differently every day to equalise the charge and discharge of the two sides of the system. The mains are all underground, insulated cables being used placed on glass insulators in an earthenware trough. A depression in the bottom of the trough serves to carry off any condensed water, and the system has given excellent results during the 18 months it has been at work. The price of current is 12 centimes per hecto-watt, or very nearly 1s. per supply unit.

Westinghouse Incandescent Lamp.—The following particulars of the new lamp, which it is claimed does not infringe the Edison patent, are volunteered by the Westinghouse Company: "The new lamp differs radically from those now in use. It requires no platinum, and is made in separate parts, so that the burner can be renewed, and the bulb and other parts used over and over again. Furthermore, by means of an important discovery, the burner is rendered stable, its efficiency increased, its life prolonged, and its normal candle power maintained. The manufacture of these lamps will be carried on almost entirely by machinery, the first cost being thus reduced, so that with the advantages obtained from the reuse of bulbs, a saving of from 30 to 50 per cent. to consumers in the cost of incandescent lamps for a given service will be effected. These lamps are in appearance a decided improvement over those now in use, and when used with a new socket designed for the purpose a further reduction in cost of lamp renewals will be effected, as no base attachment is required to make connection with the socket." Important allowances will also be made for return of bulbs to the factory. It is seen that the Westinghouse Company are certainly not content to set down tamely under the Edison monopoly. It is necessary to point out that only the second claim of Edison's patent is upheld, the other three claims having been held by the Court not to be infringed. The lamp is made under the old Sawyer Man patent.

Waste Coal.—We are accustomed to dissertations on the enormous wastefulness of the present methods of using coal for steam engines, but it would seem in reality as if the waste were often greater underground than above ground. Such is stated to be the case by Mr. James Tonge, F G S., in the course of a paper read by him recently before the members of the North Staffordshire Mining Institute. It is quite possible that here electricity may come to the aid of colliery managers, with specially designed coal-cutters for the various class of coal, for the waste alluded to is mostly in the breaking of the coal into almost valueless slack. It would really seem as if the best thing to be done at the present time would be to obtain carefully digested reports as to the exact state of the requirements for collieries in hauling, cutting, lighting, signalling, and testing for dangerous gases. Fully put before electrical engineers from the colliery engineer's point of view, there would probably be little time before the requirements would be fully and exactly satisfied. Is it not worth the while of the Mining Institute, or some body like the Society of Arts or our own Institution, to formally apply for and report upon the present requirements of colliery engineers? It would lead to better and more economical methods of colliery work, and show the exact fields of business that are open to electric motor men and electric lampmakers, while secondary-battery makers, dynamo and wire makers would all participate in the benefit.

Chamber of Commerce.—A meeting of the Electrical Trades' Section of the London Chamber of Commerce was held last Friday, at the offices of the Chamber, Botolph House, Eastcheap, at which the rules and regulations of the Board of Trade regarding the electrical industry were discussed. The chair was occupied by Major Flood Page. Mr. Crompton alluded to the correspondence between the section and the Board of Trade in 1890 relative to two of the Board's rules as to overhead wires—the thickness of insulation and suspending wires. They were given to understand at the time that the Board would not consent to modify these rules, as requested, until they had been pressed to do so by some authority as influential as the Council of the Institute of Electrical Engineers, which originally advised them. He had accordingly communicated with the Institute, and Prof. Ayrton had at once taken the matter up, and a committee of the Institute had been appointed to go into it. It was quite clear, however, that the investigation desired by them must now be wider than that originally contemplated, and must, in fact, embrace the whole subject of the Board's interference with the electrical industry. He did not believe that Parliament had ever intended that the Board of Trade should deal with them in regard to matters of the smallest detail. M. Emile Garcké, the Chairman, General Webber, and other gentlemen took part in the discussion, the general feeling being that it would be advisable in the first place to try and induce the Council of the Institute of Electrical Engineers to modify the advice which they originally gave to the Board of Trade. Eventually a resolution was passed appointing a sub-committee of the section to consider the whole question of the regulations of the Board of Trade, and to confer with the Institute of Electrical Engineers.

Information.—Not only should we call attention to the long series of articles which are appearing in the *Belfast Evening Telegraph*, but we should also refer to an excellent series of articles—which has been concluded with the eleventh article—in the *Glasgow Herald*, on the tramway motor question. A vast amount of information has been disseminated in this manner, and so far as we can see the information has been fairly given. A number of the more important firms which have carried out traction work are mentioned, but we should like to add a little information about a short line, which to us is somewhat unique. Southend is fairly well known as possessing a pier over a mile and a quarter in length, and having on this pier an electric tram line which was constructed by Messrs. Crompton and Co. We think this line has been running, during the season, now for something like three years. The engine is one of Davey-Paxman's, and has never given any trouble; the dynamo is one of Crompton's, and also has given no trouble. The engineer in charge of this installation must be congratulated that, with no second dynamo, he has been able during the whole of this period, not only to run the tramcars as required, but also to light the pier with arc lights and the pavilion with incandescent lights. None but those who have had charge of an installation with what may be termed no stand-by, will understand the responsibility which attaches to the keeping of everything in due order for the multitudinous work. As we say, this line is a mile and a quarter in length, and we imagine that what can be done on the mile and a quarter can be done on a line twice or 10 times the length with the necessary suitable apparatus. We understand that, during this slack season, the installation at Southend is to be thoroughly overhauled.

The Institution.—The next meeting of the Institution takes place on November 10, and our contributor, Mr. S. F. Walker, has taken the opportunity of giving expression to opinions which, to say the least, are not quite favourable to the administrative system of the Institution. But Mr. Walker suffers in not being behind the scenes

quite so much as the papers he refers to. The dealings of the Institution with the technical press are much on a par with the proceedings of the heathen Chinee. Readers of our esteemed contemporary, the *Electrical Review*, may remember towards the end of the spring session it had occasion to call attention to the vacillating policy of the Institution. We hardly considered the matter worth attention, but we find some of the members are by no means pleased with the condition of affairs. Let us recall the matter. In earlier days the technical papers were allowed to make their own reports. Then came a time of authorised reports, which meant that the papers and reports were officially sent to the various editors. Towards the end of the spring session these official reports were stopped. Our contemporary, like others, made its own arrangements, but these were officially objected to. What will be the course pursued during the forthcoming session, we neither know nor care. It would not be difficult to give the names of the busybodies on the Council to whose initiative these proceedings are due, but the Electrical Engineers are not in the habit of worshipping such heroes. In our opinion the official reports were fairly satisfactory, and might well have been continued. Mr. Walker, however, is quite right in his contention, that *some*, not all the members of Council, have the idea that the Institution is run for their special benefit. He is right, also, in the discreditable way in which men are elected—men who have not the remotest knowledge of aught electrical, nor any pretence to such knowledge.

Dejardin's Electric Meter.—M. Déjardin, the well-known constructor of the Jacquemier and Marès meters, has himself brought out a new watt-hour meter with almost continuous integration. His object has been to provide a strongly-built cheap meter, giving exact readings, and using less current than is usual in most meters. His meter consists of an electrodynamometer, a weighing mechanism, clockwork movement, and totalising gear. The electrodynamometer is composed of a movable fine-wire coil between two fixed thick-wire coils, the latter wound inversely to act similarly upon the thin-wire coil; the thick coils take the whole current measured, and the thin coil is in shunt. The movable thin coil is connected to a balance beam by means of a suspension rod, and the couple it exerts under the influence of the current is proportional to E I. The method of integration is peculiar. The balance arm of the weighing mechanism is furnished with a wheel, which, when the beam is in an horizontal position, gears with the clockwork of a 40-day pendulum clock; this latter is, by its construction, connected to the totaliser every five minutes. The movable coil is connected to a very flexible chain, known in Paris as a "chaine de regence"; this it pulls over in proportion to its displacement. The clockwork on connection winds back the chain until a sufficient length is unwound to overcome the weight of the balance arm, when it swings down, coming out of gear, and stopping, of course, the registration. The chain is wound off continuously during the five minutes' interval, and if after a reading is finished more lamps are thrown on, the balance goes up at once and the supplement of energy used is registered. The registration is thus continuous, except for a period of two or three seconds in each period of five minutes, when the chain is being wound back into place, and the integration is thus continuous for 297 seconds out of every 300. The expenditure of current is practically nil, as the movement is carried out by clockwork, but meters are also made with automatic electric winding. Three screws are supplied to keep the movable parts in place for safety in transport. Illustrations of the Déjardin meter are given in *L'Electricien* for October 22, with description, of which the above is a short abstract.

Theory of Accumulators.—M. Bidard, professor of chemistry at Rouen, has recently expounded his theory of the action of lead accumulators. This theory is published in the *Bulletin Internationale de l'Electricité*, and the author considers that it "explains all the interactions of accumulators, and will lead to important improvements in their manufacture"—viz: (1) Reduction of volume and weight of cells; (2) greater conductivity and abrogation of alteration of lead; and (3) rendering the actual output much nearer to the theoretical output. He first of all states as an absolute principle that no other accumulator is possible than lead immersed in sulphuric acid, and that with other metals "accumulation" cannot take place. The theory of accumulators, he says, is of great simplicity, and may be thus defined: When a current of electricity is passed between two plates of lead insulated and placed in sulphuric acid solution, the acid is decomposed into sulphur, which combines with one of the plates to form a black sulphite of lead, and oxygen, the latter attacking the other plate to form brown peroxide of lead. The chemical formula is thus:

$$2\,SO_3 + 5\,Pb = 2\,S\,Pb\text{—black sulphite of lead.}$$
$$3\,Pb\,O_2\text{—brown peroxide of lead.}$$

This reaction shows itself by the two distinct colours brown and black. This is further confirmed by analysis. From numerous experiments the important fact has been proved, that after charge the accumulator becomes heavier by the weight of the fixed oxygen and sulphur, and consequently a part of the sulphuric acid of the solution disappears, and its elements are to be found in the sulphite of lead and the peroxide. When the cell is discharged the two elements, sulphur and oxygen, fixed in the lead recombine to form sulphuric acid. These important experiments can be easily reproduced with small plates of lead in a glass vessel. M. Bidard considers that no "accumulation" is possible except with lead, as the lead, sulphite of lead, and peroxide are neither attacked nor even altered by sulphuric acid. It is otherwise with copper, iron, or zinc, which do not resist sulphuric acid, as the acid will dissolve their oxides. Lead is the only metal which enables "the two electricities" to be fixed in their solid combinations—sulphite and peroxide of lead, insoluble in sulphuric acid. The lead must be as pure and as divided as possible, and old metal from pipes, spouts, etc., must be avoided, as these contain noticeable quantities of zinc, and even antimony, which give rise to troublesome actions and tend to destroy the plates. The sulphuric acid of commerce is sufficiently pure: it contains sulphate of lead, which is separated when it is mixed with water sufficient to bring it to 10deg. This should be removed by deposition or filtration to prevent it forming a coating on the plates. To arrive at perfection with accumulators there yet remains, says M. Bidard, several problems to be solved: 1. For a certain quantity of lead what is the "quantity of electricity accumulated"? 2. What is the best method of obtaining divided lead? 3. Preservation of the plates when not in use, and means of cleaning without taking to pieces to remove the sulphate. 4. By employing sulphuric acid of 10deg. there is always electrolysis of a certain amount of water, hence waste of electricity—research is needed to find if this can be avoided by employing acid of greater density. This is the professor's note upon his new theory, which, heralded with some *éclat*, is to greatly improve the manufacture of accumulators. The terminology, as will be seen, is loose for a scientific theory, and it hardly seems as if this disquisition, though stating the matter succinctly, will add greatly to the present knowledge of the action of secondary cells.

LIFE AND EFFICIENCY TESTS ON INCANDESCENT LAMPS, WITH A FORMULA FOR DETERMINING THE RELATIVE VALUES OF THE DIFFERENT MAKES OF LAMPS.*

BY P. G. GOSSLER

The following is an account of a life and efficiency test on various makes of incandescent lamps, made in the testing room of a large electrical illuminating company. The object of the test was to determine the best lamp for central station use, by which is meant a lamp that is most satisfactory to the customer, and at the same time most economical to the illuminating company. The results are of a special value from the fact that throughout the test the conditions under which the lamps were run, were made to conform with the conditions imposed upon lamps in central station practice.

Ten different kinds of lamps were secured for the test, most of them coming from the storeroom of the illuminating company, or bought in the open market. Twenty lamps were taken at random from each lot of lamps, and carefully measured for candle power and current consumption at 50 or 100 volts, according to the markings on the lamps. The lamps were placed on a large lampboard which had been made for the purpose, having heavy copper bars at the bottom, which were fed from a bank of converters on the three wire system. The 50-volt lamps were so connected that the two sides of the three wire system were equally balanced, the 100 volt lamps being connected to the outside wires of the same system. This arrangement secures exact equality of voltage on all of the 200 lamps placed on the board, except that the voltage on the 100 volt lamps was double the voltage on the 50-volt lamps. The rated capacity of the bank converters, to which the 200 lamps were connected, was 240 lamps. A number of lamps broke during the first few hours of the test, which reduced the load on the converters to about three quarters of the rated capacity, this being approximately the average load in practice. The bank of converters was connected to the distributing mains of a commercial circuit, to which about 2,200 commercial incandescent lamps were connected, and the lamps in the test board burned under the same conditions of pressure as the lamps in customers' premises. The lamps were burned continuously, candle-power and current measurements being made at a pressure of 50 and 100 volts when the lamps were new, and after they had burned 100, 300, 600, 1,000, and 1,700 hours. The voltage at which the lamps burned in the lampboard was measured by a standard voltmeter, the measurements being made as often as 30 times a day during the early part of the test, but this was not continued during the entire time, the measurements being made but three or four times a day during the latter part of the test. It is shown in the tables that the average E.M.F. on the 50 volt lamps was from 51 to 52 volts, while on the 100 volt lamps it was double this. No effort was made to keep the current and E.M.F. on the lamps constant at 50 volts during the life test, the lamps being burned at the average voltage on the circuit from which they were fed. The average E.M.F., as stated in the tables, was from 51 to 52 volts. However, it was carefully controlled during the candle-power and current measurements, all measurements being made at 50 and 100 volts. The arrangements provided secured for the lamps in the test room the same conditions as to voltage, etc., that they had on the other lamps that were connected to the station, and especially the lamps connected to the distribution mains, from which the test-room drew its supply of current. After the 200 lamps had run 400 or 500 hours, a second test was started on five of the 50 volt makes, which seemed to be leading in the early part of the first test. The purpose of the second test was to find the effect on the lamps of increasing the pressure about 10 per cent. For this purpose 10 new lamps of each of the five kinds were placed on a second lampboard, with converters so connected that they would burn at 10 per cent higher pressure than the lamps in the first test. The 50 volt lamps in the first test are lettered A, C, E, H, J, L, O, and P, and the 100 volt lamps are lettered G and J. The lamps in the second test are lettered B, D, F, K, and N.

There are in all 15 groups of lamps, representing 13 groups of 50-volt lamps, and two 100 volt groups. The 13 groups of 50-volt lamps represent but eight different makes, five makes in the first test being duplicated in the second test. The two 100 volt groups in the first test were made by the same makers as two of the 50 volt groups. The tables and curves for the same kinds of lamps are lettered as follows: A and B are of the same make, C and D are of one make, E and F are the same, and J and K are the same, and those lettered L and N are of the same make.

The 100-volt group marked G is from the same factory as the 50 volt lamps marked H, and the 100 volt group marked I is of the same make as those marked L and N. The last measurements were made after the test had been running 1,700 hours, and it will be seen from the second and fifth columns, in the same tables, that there are [illegible] lamps that would not be considered dead for ordinary lighting purposes, especially on circuits that are run as this test circuit was, at an average voltage of 2 per cent to 4 per cent. above that for which the candle-power measurements were made.

The candle-power measurements were made on an ordinary Bunsen sliding photometer, the scale of which was 96in. in length, and marked to read directly in candles

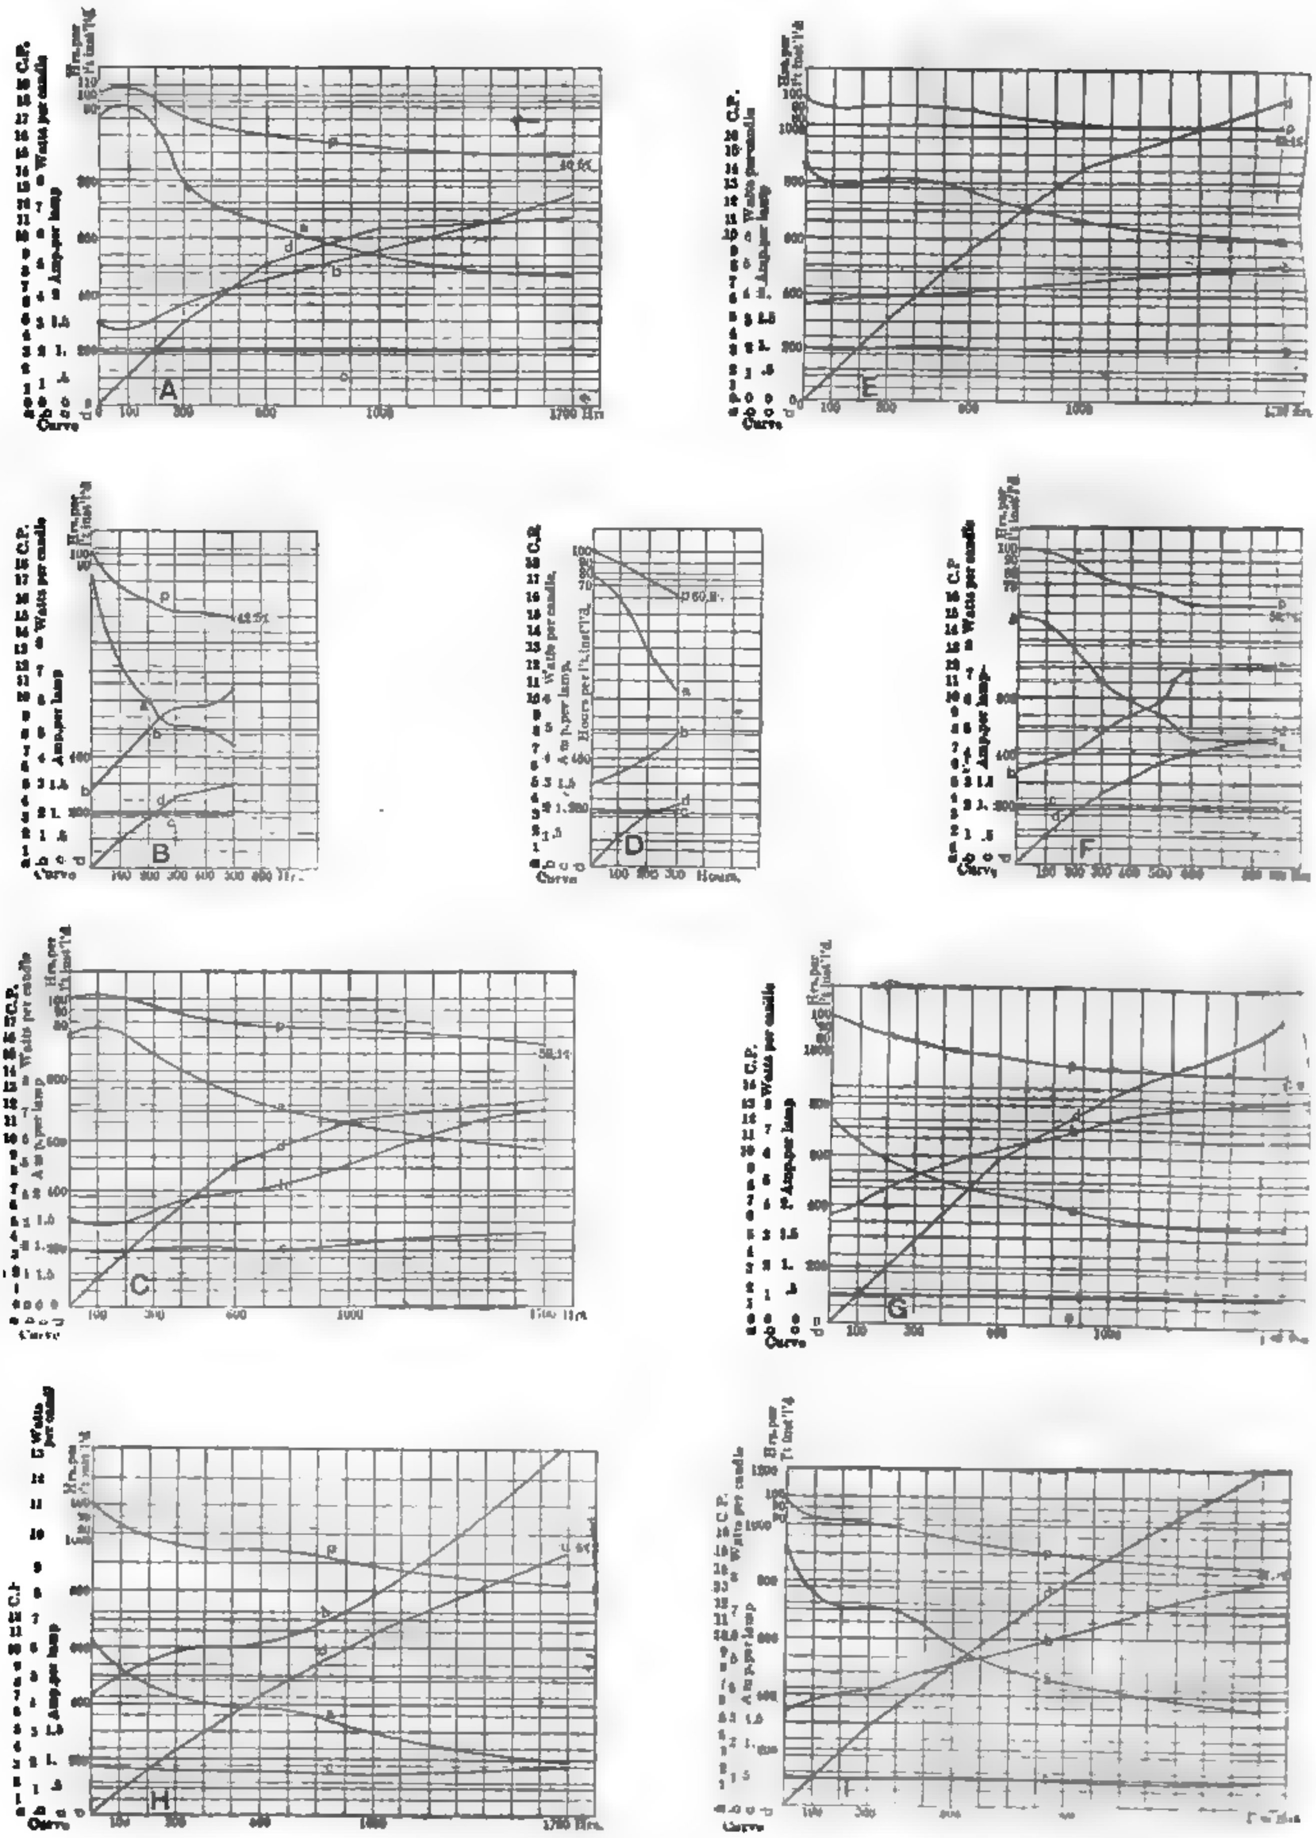
The standard used was a selected incandescent lamp, placed on the same circuit as the lamp being measured. The object of doing this was to secure comparative candle-power measurements that would be correct for all the lamps at exactly 50 volts, and any error from unavoidable variations in voltage on the lamp being measured was approximately neutralised by the varying of the voltage on the standard to exactly the same extent, or keeping the voltage on the two lamps exactly equal. More accurate comparative measurements were secured in this manner than can be had when an ordinary gas standard of candle-power is used. The standard lamps were secured by

taking 100 lamps and seasoning them by burning them 10 hours at a high voltage, and selecting from these as standards lamps which measured 16 candles. The efficiency of the were made with two Siemens electro-dynamometers. The lamps were measured for current in groups of 10, and the average current of the group taken.

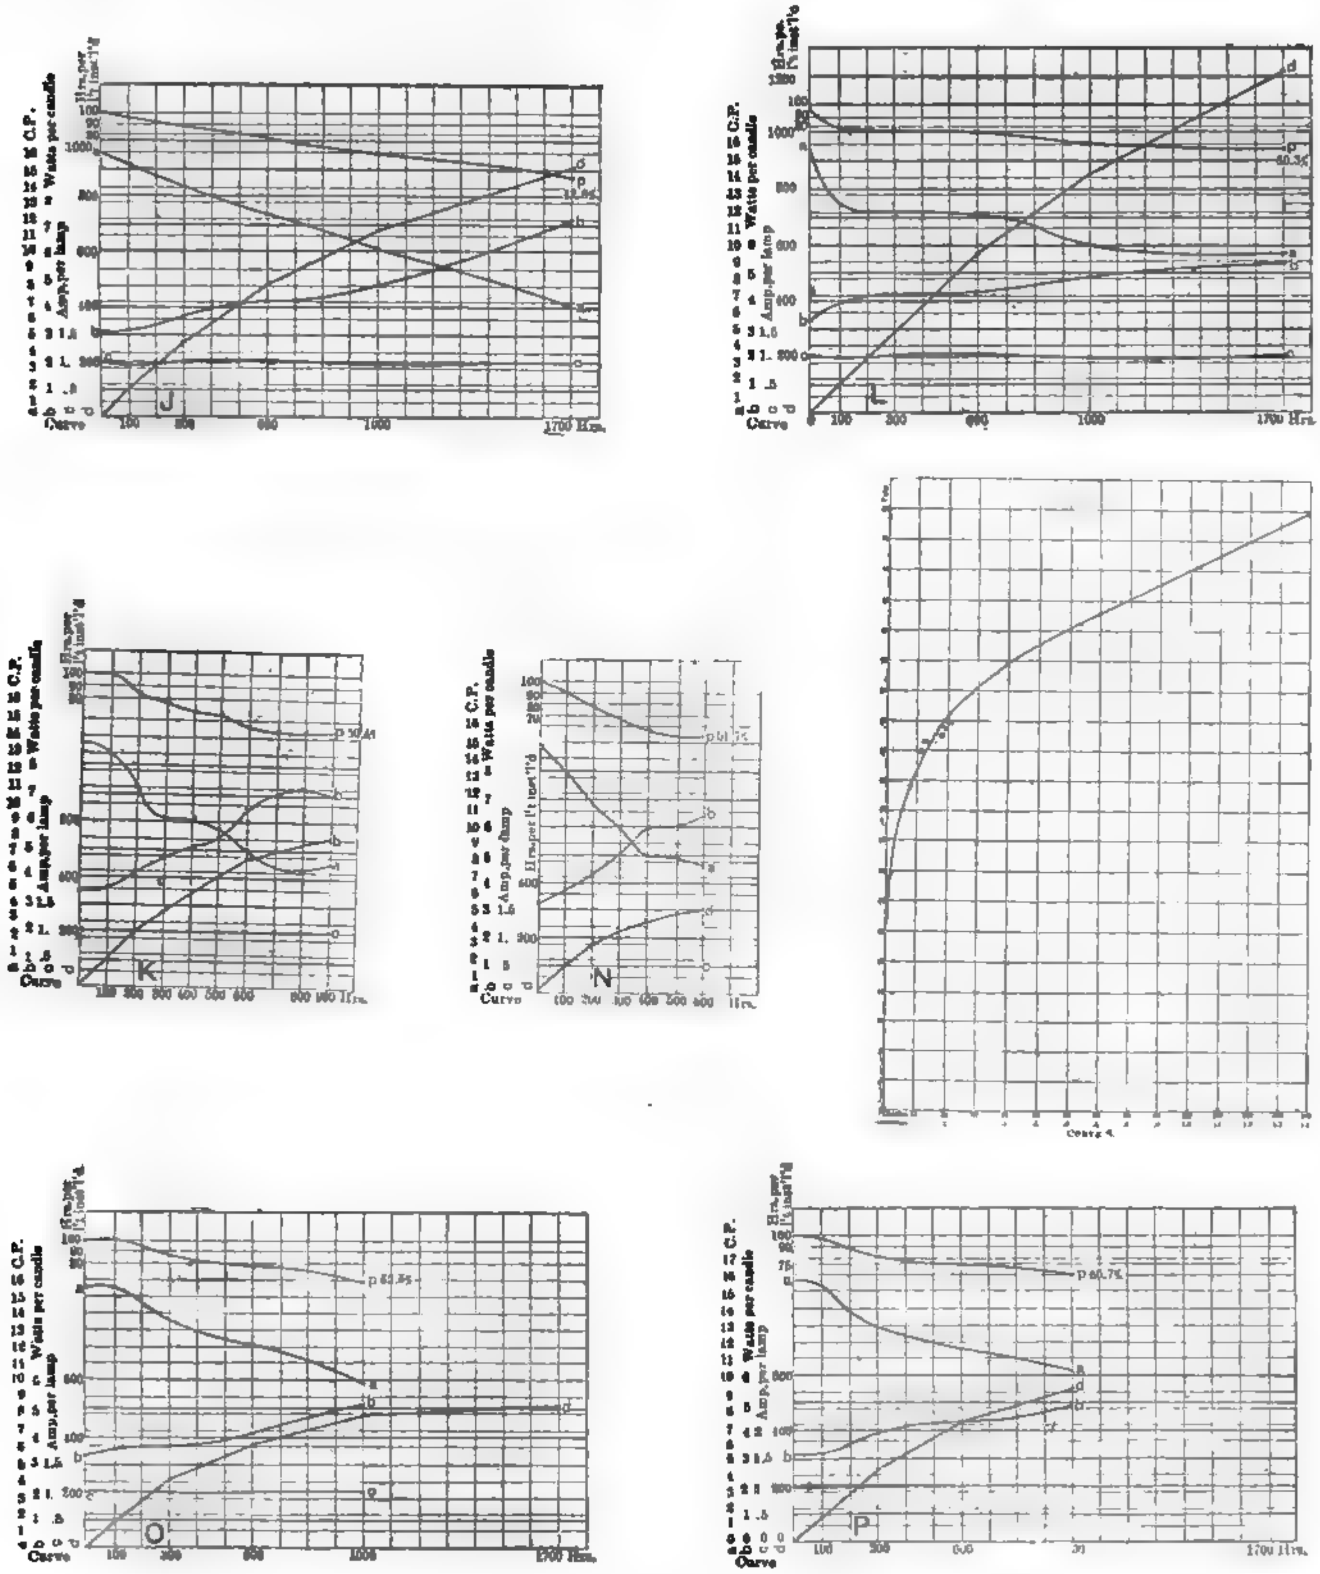


Curves A, B, C, D, E, F, G, H, and I, showing the Results of Life and Efficiency Tests of Incandescent Lamps.

standard lamps was approximately the same as that of those being measured. The voltage was taken by means of a carefully standardised voltmeter, and the current measurements

The results of the tests on the different makes of lamps are given in the tables and plates, for which the following explanation will be sufficient. Each group of 20 lamps is

designated by a letter, and the plates bear the same letters as the tables, from which they are constructed. The curves on the different plates, representing the same thing, are all drawn on the same scale and bear the same letter throughout, as on plate A, curve A represents the candle-power, measured at 50 volts, at various stages during the test; B is the curve representing the watts per candle, at 50 volts; C the curve giving the refer to curve A, and represent average candles per lamp at 50 volts; the vertical row lettered "b" refers to curve B, and represents average watts per candle at 50 volts; the vertical row "c" refers to curve C, and represents the average amperes per lamp at 50 volts for all unbroken lamps; the vertical row "d" refers to curve D, and represents the average hours burned per lamp-hour, burned by all of the lamps, referred to by the curve, divided



CURVES J, K, L, N, O, P, showing the Results of Life and Efficiency Tests of Incandescent Lamps.

amperes per lamp at 50 volts; P gives the percentage of the initial candle-power; and D gives the number of hours burned per lamp, installed for any of the time intervals at which the measurements were made; time is a factor common in all of the curves. The figures at the bottom of the plates, in horizontal rows, are common to all the curves, and represent hours that each lamp has burned. The vertical rows of figures lettered "a" by the total number of lamps originally installed in the given lot, which was either 20 or 10. The curves on the plates have been plotted from the observations made at the different periods of the time shown in the tables, and each curve represents the average result of all the measurements made on the particular lot of lamps to which it refers.

Lamps burning at a voltage above that for which they

are rated give a much greater illuminating power than 16 candles, but at the same time their life is very considerably shortened. A plate showing the effect of various voltages upon the brilliancy of a lamp is given, and the effect of a 10 per cent. increase of voltage upon the lamp may be ascertained from the tables and plates by comparing the same makes of lamps which were run in the two tests The lamps lettered L and N are of the same make, and are the lamps referred to as having been taken directly from the storeroom; but it is seen from the tables that the initial tests on these lamps vary considerably, which is accounted for by the lamps coming from different invoices, received from the manufacturers at different times. It has been observed that lamps received from the factory do not average the same candle-power and efficiency for different invoices; that is, lamps which are received in one invoice are usually quite uniform throughout that lot, but they vary considerably from lamps made at other times. Plate 8 gives the curve showing the different illuminating powers of a 16-c.p. 50-volt 52-watt lamp, for various voltages from 25 to 80 volts. The table from which this curve has been plotted is as follows:

Volts.	Amperes.	Candles.	Watts.
25	·561	·4	14·025
29·5	·645	·87	19·03
34·6	·774	2·47	26·94
40·	·898	5·1	35·92
48·	·9675	12·6	46·34
49·	1·032	15·	50 57
50·	1·055	15·8	52·75
52·5	1·0965	20·50	57·57
55·6	1·161	28 40	64·55
59·5	1·2255	39·30	72·92
62·	1·29	50·70	79·98
68·2	1·419	74·50	96 78
72·5	1·4835	103·20	107·54
78·	1·548	130·	120·74
80·	1·58	141·	126·40

From this curve can be approximately ascertained the candle-power at which the lamps in the test burned. All candle-power measurements in the test were made with the lamps in the position of maximum horizontal candle-power.

The question which first presents itself after an examination of the above tables and curves is, which is the best lamp for central station use? To get a satisfactory answer to this, all of the conditions surrounding the initial cost, and cost of operating the plant, will have to be considered.

For this purpose the cost of producing light may be divided into three parts, as follows:

A. That portion of the cost of service per lamp-hour that is not affected by the average efficiency and life of the lamps, and such portion of the maintenance, operating and general expenses as is not increased by increasing the current consumption per lamp-hour.

B. The cost per lamp-hour for coal, water, interest, and depreciation on lines, dynamos, engines, etc., and such part of the expense of the service as increases proportionally to the amount of current served per lamp-hour, and as the maximum station output.

C. The cost of the lamps per lamp hour, and the expenses per lamp-hour of replacing exhausted lamps, which is equal to the cost of one lamp plus the cost of exchanging one exhausted lamp, divided by the average life of the lamps.

These divisions should be made so that the sum of A, B, and C will represent the total cost of service per lamp-hour. That part of the cost, exclusive of lamp renewals, that does not increase with an increase of current per lamp-hour should be classified under A. That portion of the cost of service per lamp-hour, exclusive of the cost of renewing lamps, that increases proportionally to the current consumed per lamp-hour, should be classified under B. Under the first division A is the cost of shades, sockets, fuses, fixtures, subsidiary cables and ducts, etc., and such proportion of the operating and general expenses as it is not increased by increasing the current consumption per lamp-hour.

The values of A, B, and C, representing the above divisions of cost, having once been established for a lamp of any given efficiency and length of life for any particular central station, the cost of service per lamp-hour for this same station with any other lamp which has a current consumption of x times the current consumption per lamp-hour of the first lamp, and having an average life of y hours, would be

$$A + x B + C',$$

C′ being the cost of one of the new lamps, plus the cost of replacing one exhausted lamp, divided by y, the average hours of life of the new lamp. Substituting in the formula approximate values for the above expressions, and applying the assumed values to the three makes of lamps lettered J, I, and H, we get the following:

Let the cost of service per lamp-hour of a central station burning lamps L (see curve L), having an average life, under actual conditions, of 1,200 hours, a current consumption of 51·5 watts at 50 volts, or 53 watts per lamp at the actual voltage burned in use, an average candle-power during the life of 10·7 candles per lamp, when measured at 50 volts, or an average candle-power of 12·2 candles at the actual voltage burned, be as follows:

A— ·45 cents.
B— ·28 cents.
C— {Cost of lamp, 50 cents.
Cost of exchanging one exhausted lamp, 1·5 cents.
Average lamp life, 1,200 hours.

Substituting these in the formula, we have

$$\cdot45 + (\cdot28 + 1) + \frac{50 + 1\cdot5}{1{,}200} = \cdot7729 \text{ cent,}$$

which is the cost per lamp-hour for supplying light with the make of lamps lettered L.

Let the cost of service per lamp-hour of a central station burning lamps J (see curve J) having an average life under actual conditions of 700 hours, a current consumption of 50·5 watts per lamp, at 50 volts, or 52 watts per lamp, at the actual voltage burned in the test, and having an average candle-power during life of 12·2 candles when measured at 50 volts, or an average of 14·1 candles when measured at actual voltage burned be:

A— ·45 cents.
B— ·28 cents.
C— {Cost of lamp, 40 cents.
Cost of exchanging one exhausted lamp, 1.5 cents
Average lamp life, 700 hours.

$$x - \frac{1\cdot01}{1\cdot03} = \cdot98.$$

Substituting in the formula,

$$\cdot45 + (\cdot28 \times \cdot98) + \frac{40 + 1\cdot5}{700} = \cdot7886 \text{ cent,}$$

the cost per lamp-hour for supplying light with the lamps lettered J.

It is seen that the cost of service per lamp-hour is less with the lamps lettered L than with the lamps lettered J, but if we find the cost of service for candle-power of light given by dividing the cost per lamp-hour of both makes by the average candle-power given by the respective lamps while burning, we have for the lamps L, $\frac{\cdot7729}{12\cdot2} = \cdot0633$ cent, equals the cost per candle-power hour, and for the lamps J $\frac{\cdot7836}{14\cdot1} = \cdot0555$ cent equals the cost per candle-power hour, making a difference of ·0078 cent per candle-power hour in favour of the lamps lettered J, which have the cheaper initial cost of the two makes, L and J.

Applying the formula the same way to find the cost of service per lamp-hour under the same conditions as above, and using the lamps H, we have the following:

Let the cost of service per lamp-hour of a central station burning lamps H (see curve H), having an average life under actual conditions of 375 hours (this being a very liberal allowance for this lamp), and having an average current consumption of 44·8 watts per lamp at 50 volts, or 46 watts at the actual voltage burned in the test, and

having an average candle-power during life of 7·6 candles, when measured at 50 volts, or an average of 9·1 candles, when measured at the actual voltage burned, be:

A— ·45 cents.
B— ·28 cents.

$$C\text{—}\begin{cases}\text{Cost of lamp, 30 cents.}\\ \text{Cost of exchanging one exhausted lamp, 1·5 cents.}\\ \text{Average lamp life, 375 hours.}\end{cases}$$

$$x\text{—}\quad \frac{\cdot896}{1\cdot03} = \cdot87$$

Substituting in the formula,

$$\cdot45 + (\cdot28 \times \cdot87) + \frac{30 + 1\,5}{\cdot375} = \cdot778 \text{ cent},$$

which is the cost per lamp-hour for supplying light with the make of lamps lettered H, under conditions assumed.

Dividing the cost of service per lamp-hour with the lamps H, by their average candle-power per hour, under the above conditions, we have $\frac{\cdot778}{9\cdot1}$ = ·0855 cent per candle-power hour, making a difference of ·0222 cent per candle-power hour in favour of the lamps lettered L, and a difference of ·03 cent per candle-power hour in favour of the lamps lettered J.

This formula applies only for comparing the cost of producing light with lamps having different costs, efficiency, and average lamp life, when they are to be burned in the same plant and under the same conditions of average lamp-hours burned per lamp installed, and the same maximum number of lamps burning for a given number of lamps wired, etc. Value B in this formula includes the coal consumption and the materials, which practically vary proportionally to the watt-hours output required for providing the light. It also includes the interest and depreciation on the plant, which must be enlarged when the lamps consume large amounts of current, because the generating and supplying capacity of the plant must be proportional to the maximum output called for by the lamps. In many plants the interest and depreciation account will form quite a considerable portion of the factor B, and as a large value to the factor B makes a showing against a high consumption of current per candle-power hour very bad it would appear that any lamps installed in a plant that did not burn at the time of maximum current output from the station could be economically used of a poorer efficiency with longer life than lamps that do burn at the time of maximum output, because any additional demand for current on a plant that is not a call for a current at the time of maximum output does not require an increase of plant capacity. In estimating the best efficiency per candle-power hour, or per lamp-hour, for these lamps that do not burn at the time of maximum output, the cost of interest and depreciation entering into the factor B in the formula (in fact, all the costs that increase proportionally as the size of the plant required to serve the lights wired) should be excluded from the factor B; the result is that lamps that do not burn at the time of maximum output can be economically used of considerably lower efficiency than lamps that do burn at that time.

BOARD OF TRADE REPORT.

The following completes the appendix to the Board of Trade report as given in recent issues.—Ed. *E. E.*

LICENSES.

Title of License.	To whom granted.	Revoked or repealed.
	1884.	
Colchester Electric Lighting License, 1884.	South-Eastern (Brush) Electric Light and Power Co., Ld.	Expired July 14, 1891.
	1885.	
Dalton-in-Furness Electric Lighting License, 1885.	The Local Board.	—
St. Austell Electric Lighting License, 1885.	John Edward Veale.	—
	1886.	
Dundalk Electric Lighting License, 1886.	The Town Commissioners.	—
	1887.	
Kensington Court Electric Lighting License, 1887.	Kensington Court Electric Lighting Co., Ld.	Repealed by the Kensington and Knightsbridge Electric Lighting Order, 1889.
	1888.	
Kensington Court Electric Lighting License, 1888.	Kensington Court Electric Lighting Co., Ld.	Do. do.
Liverpool Electric Lighting License, 1888.	Liverpool Electric Supply Co., Ld.	Repealed by the Liverpool Electric Lighting Order, 1889.
St. James's Electric Lighting License, 1888.	St. James's and Pall Mall Electric Light Co., Ld.	Repealed by the St. James's Electric Lighting Order, 1890.
	1889.	
Dublin Electric Lighting License (Public), 1889.	The Corporation.	The Dublin Electric Lighting Order, 1892, scheduled to the Electric Lighting Orders Confirmation (No. 4) Bill, now before Parliament, contains a provision for the repeal of this license.
Kensington Electric Lighting License, 1889.	Kensington Court Electric Lighting Co., Ld.	Repealed by the Kensington and Knightsbridge Electric Lighting Order, 1889.
Wimbledon Electric Lighting License, 1889.	The Local Board.	—
	1890.	
Bath Electric Lighting License, 1890.	Henry George Massingham.	—
Chelmsford Electric Lighting License, 1890.	Crompton and Co., Ld.	—
Dublin Electric Lighting License (Private), 1890.	The Corporation.	The Dublin Electric Lighting Order, 1892, scheduled to the Electric Lighting Orders Confirmation (No. 4) Bill, now before Parliament, contains a provision for the repeal of this license.
Newcastle and District Electric Lighting Company's License, 1890.	Newcastle and District Electric Lighting Co., Ld.	Repealed by the Newcastle-upon-Tyne Electric Lighting Order, 1891.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 10d.	9s. 11d.	19s. 10d.

(Post Free. Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to IX. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bo[illegible] 6d., or covers for binding can be obtained, price 2s.*

THE BOARD OF TRADE AND THE INDUSTRY

Practically a meeting of the Electrical Trades' Section of the London Chamber of Commerce was held last Friday to discuss the relations between the Board of Trade and the industry. It is fine fun to have a Government department to kick—nobody is hurt; nobody takes the kicking seriously. It is assumed that the kickers have their own ends to pursue, and try to do so to the best advantage. Everybody agrees that a Government department always needs a gentle kicking, otherwise its existence would be intolerable. It treads on toes and corns, and pursues its way somewhat unconcernedly. It is given to closing its eyes and going ahead, thereby conferring sundry knocks on those who stand in its way. It is easy to formulate a tolerably lengthy list of ills which men, and especially business men, have to suffer because of the interference of a department which, after all, doesn't care a pin for the business men. Putting it bluntly, we have on the one hand an industry the members of which are intent—and all credit to them for being so—on making money. They are rather arrogant in their ways of proceeding, prone to tell you that you know nothing at all of the business in hand, cynical in the presence of any suggestion other than they make themselves, and quite certain they are right and everybody else wrong. On the other side we have a department with certain advisers—independent of business concerns—standing in the way. Naturally inert, hard not merely to convince but to allow possibility of conviction outside of formal red tapeism, is it to be wondered at that friction arises? Rather ought we not to wonder that so little friction has arisen. Mr. Crompton, in moving that a committee should be appointed to deal with the matter made some sweeping assertions that may tend to roughen, rather than soften the way of the department: "The whole question of the extent to which the Board of Trade should interfere with private electrical enterprise should be very carefully considered, and if they found that they were really having their hands tied and the progress of their industry fettered by being over-regulated, they must make an energetic protest against the continuance of such over-regulation." There is no one who knows better than Mr Crompton that so far as interference in "private electrical enterprise" is concerned, there is none. It is only when the industry comes into conflict with the general public that difficulties arise. This is clear from other sentences. "His own view was that the Board of Trade had no business to interfere in the matter of electrical supply, except in so far as regarded the protection of the safety and of the interests of the public, and also as regarded accounts and the transfer of electrical undertakings. Parliament never intended that the Board of Trade should regulate the industry in the smallest details." Here we take leave to differ from Mr. Crompton. Parliament intended that the public should be safe, and the Board of Trade is compelled to enter into the minutest details of electric supply in order to ensure this safety. If there were no black sheep in the electrical fold, a good many details could be left to the industry to arrange; but the Board of Trade has to legislate for the black sheep, and thus,

in many cases, hangs a millstone round the necks of those who are honest, and who believe in a name and reputation for good work. It is only in details which affect the public that the Board of Trade interferes. If a private installation is put up in a gentleman's house or in a factory, the Board of Trade has nothing to say in the matter. The only three people concerned are the purchaser, the seller, and the fire insurance offices. You may, so far as the Board of Trade is concerned, put up overhead or underground wires, or no wires at all—you may use high pressure or low pressure. They do not legislate in this case. We hold that the Board of Trade, even with its inertness, has pursued a fairly beneficial policy so far as the development of the industry is concerned, in that it has shown a decided preference towards municipal action—hence we cannot quite accept any sweeping condemnation of the Board of Trade officials. They have responsibilities, and it is better for them to be on the safe side, rather than on a too lenient footing. What we would like to see — what we would support to the utmost — is an increase in the flexibility of the Board of Trade's rulings. Let their rules differ from those of the Medes and Persians—let red-tape acknowledge and act upon the fact that circumstances alter cases; that, for example, there are certain times and places where overhead wires are practicable, where a variation of insulation will cause no harm, and where a relaxation of rules will not endanger the safety of man, woman, or child, but would give an opportunity for an installation that under the rigid rules cannot be carried out.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

A DISCLAIMER.

SIR,—I see with great regret that my former colleague and collaborateur in various communications to the Institution of Electrical Engineers and other scientific societies, Dr. Arthur Harries, has issued a report in favour of the electropathic belts of Mr. Harness.

I must therefore ask to be kind enough to allow me to make known through your columns that my connection with Dr. Harries ceased about a year ago.—Yours, etc.,

H. NEWMAN LAWRENCE, M.I.E.E.

WRITING ON THE CLOUDS.

SIR,—On Thursday night, October 6th, 1892, from the grounds of the camp of the "Buffalo Bill's Wild West," we succeeded in placing the luminous letters "B U F" on the clouds, which letters were seen by hundreds of people, and from a good number of whom we received congratulations on having accomplished this surprising scientific feat.

From that date to the present time we have frequently repeated the experiment, and have placed Colonel Cody's portrait, not only on the clouds, but also on artificially-made clouds and on a secondary beam of light as a background.

These experiments have been witnessed by hundreds of people, and were carried on under the auspices of Colonel Cody (Buffalo Bill) and Mr. Edward Curtice, whose invention we were engaged in developing.—Yours, etc.,

R. J. CANAVAN, Superintending Electrician,
H. JACKSON, Electrician,
Earl's Court Exhibition, Oct. 24th, 1892.

P.S.—The above invention is being demonstrated at Messrs. Crompton and Co.'s works, Lillie Bridge-road, West Brompton, every evening this week after 8 p.m.

REVIEWS.

Electric Traction. By ANTHONY RECKENZAUN, C.E., M.I.E.E. Biggs and Co., Salisbury-court, Fleet-street.

The issue of a book devoted solely to electric traction is an indication of the growth of this branch of electrical engineering, and also of the need for specialists in every industry. Mr. Reckenzaun states in the preface of his book that "he has endeavoured to make it a concise summary of the methods now in use, and of the steps which have led to the present stages in the perfection of the art of electric traction."

Our first impression on reading this book is that it is in places prejudiced by its conciseness. It is throughout crowded with most valuable information, the results of long and expensive trials carried out by the author and others who have devoted their time to the subject, but some results are stated without giving sufficient data to enable the average reader to follow the reasoning. The mathematical treatment of the subject is extremely easy to follow, and curves are largely used to represent graphically the results obtained. The book will be of great use as a reference to all tramway engineers, and will be invaluable to electrical engineers commencing traction work.

The first chapter is devoted to the early history of electric motors and to brief explanations of the principles of motor design and testing. Mr. Reckenzaun has adopted the Kapp formulæ in designing, and uses the Kapp unit of induction generally. It is a pity, however, that, having done so, he should, as on page 23, introduce the C.G.S. lines per square centimetre without explaining the relations between the two units.

The second chapter opens with a few considerations of electric transmission of power for other purposes than traction, and a concise description of the Lauffen-Frankfort transmission is given. This is followed by about 50 pages of most useful information on the tractive force required on tramcars and on the fluctuations of power met with in practice. Calculations and curves are given, based on experimental runs on nine different roads under varied conditions. In one case, for example, it was found that an experienced driver used 25 per cent. less power on a given section than a nervous and inexperienced man.

The details of the electrical and mechanical design of motors and their gearing are discussed in the next chapter. Due to what is clearly a slip, the example given of motor design is very misleading. The maximum induction in the armature is stated to be 12 Kapp lines per square inch, and that in the magnets to be 10. In a tramcar motor, where weight is an important factor, 20 and 16 lines respectively are the more usual densities. Of the various gears described, Mr. Reckenzaun appears to commend the single-reduction motor with spring suspension of the field magnets. Speed-regulating devices are fully described, and the evidence given points to the use of subdivided field windings as the most economical method of regulation.

The fourth chapter treats exclusively of the conductors and means of collecting the current. Almost all of the systems of mains which have been tried with any measure of success are described, but special attention is given to the overhead system, 50 pages being devoted to this alone. The question which wire should be earthed, when the earth return is allowed, to reduce the corrosion appears to be doubtful, but where possible a large earth-plate in the station connected to the positive terminal is recommended.

Mr. Reckenzaun next takes up the consideration of storage batteries from the practical point of view, and clearly points out what faults may be expected. He considers that the weight per horse-power hour of accumulators has not been reduced during the last few years.

The sixth chapter consists of a series of descriptions of 12 various electric railways and tramways, examples being given of each of the various distinct systems. In each case the salient features are pointed out, and such details as leakage on the line, the grades and curves of the permanent way, etc., are given to make some comparison to be formed of their relative advantages. The Central London Railway, which is to be constructed on similar lines to the City and South London Railway, is described, and it will

be interesting to compare the estimates given of the power required, and the cost of running, with the actual figures obtained when the line is completed. We are surprised to note the leakage found on the Blackpool line, which is stated to give a mean loss of 7 h.p., and rises to 30 h.p. sometimes when starting. A few particulars are given of the proposed St. Louis and Chicago Railway, on which the speed of 100 miles per hour is to be the normal rate. The general arrangement appears feasible, but we should like to have a few more practical details of the construction.

Chapter VII. is devoted chiefly to the efficiency of electric traction. The author regrets that so few practical tests have been made, but he has collected enough to show the values which may be expected. We see that in two instances the power given to the cars was only 25 and 37 per cent. of the indicated horse-power of the engine. This leaves an ample margin for improvement. In another case, where the regulation was carried out by resistance placed in series with the motor, it was found that 45 per cent. of the power given to the car was wasted in the rheostat.

The last chapter gives the working expenses on a number of well known lines, but the accumulator system is again conspicuous by its absence. The cost of upkeep is in each case dissected carefully and expressed in pence per car mile. The economy of electric traction can be seen from these figures, which will also be of assistance in preparing estimates for new lines. The author has wisely left out the comparison of electric traction with traction by other means, as all such comparisons are necessarily based on the condition of a particular line, and the general conclusions drawn are very apt to be generally misleading.

Altogether, we congratulate Mr. Reckenzaun on the amount of valuable information he has given in the first book on this subject, and trust he will find time to considerably enlarge the second edition, which should soon be demanded. The book has an ample index, and is well illustrated, but we think that titles placed under the illustrations would help the reader. We confidently recommend this volume to all practical men interested in traction work.

INSTITUTES v. JOURNALISM.

BY SYDNEY F. WALKER.

What may be termed the higher education of those who are actually practising any of the branches of engineering is mainly carried on by means of the two channels through which men who are making experience, or who are thinking out different problems connected with the work they have in hand, place the results of their thought and experience before their fellow workers. The papers read before the leading scientific and engineering societies, with the discussions which follow, form a record whose value can hardly be over-estimated. To be a member also of certain institutes, such as the Civil Engineers, and, in a lesser degree, the Mechanical Engineers and the North of England Institute of Mining Engineers, confers a sort of brevet rank which should be worth any number of testimonials, and should enable a man to take a good position in any part of the civilised world. The great care exercised by the councils of these institutes before admitting candidates as members is a far better security for their being masters of their craft than, as was very properly pointed out some years since, any form of registration or examination could possibly afford. Further, the world-wide reputation of these institutes, and the large area over which their *Transactions* are circulated ensure the writers of papers an audience of the very men they want to reach, and often brings them into correspondence with men who may be of considerable service to them in their struggles for success in their profession. But, unfortunately, many of the minor institutes, while imitating the older ones in many of their methods, are too often managed with a total disregard of everyone's convenience and of everyone's interest, except those of the members resident in London, and more particularly of a small knot of men who prac[illegible] rule them.

Institutes live by three things: By subscriptions, by papers, and by discussion. But in the case of many institutes, though they depend very largely for their revenue on provincial members, absolutely nothing is given those members in return beyond the *Transactions* and notices of meetings. The *Transactions* always come to hand months after the paper has been read, and often when all interest in it has passed away, while the members and non-members can read both papers and all that is supposed to be worth printing in the technical press at the time they are issued. The notices of meetings also are often practically worthless. A post card containing two lines to the effect that Mr. So-and-So will read a paper, say, on "Arc Lamps," conveys actually no information at all, unless the member receiving the notice is intimately acquainted with the work Mr. So-and-So has been engaged on. Such a notice is fairly passable for a local debating or naturalists' society, where it is very little trouble to attend the meeting, and where everyone knows what to expect from the member who is to read a paper or from the lecturer who has been engaged. But even the better class of those societies nowadays give considerably more information than is given by the notices quoted above. Usually a brief outline is given, under different headings, enabling those who think of attending the meeting to form a very good idea of what they are to hear. The leading institutes mentioned also give a very full abstract of each paper that is to be read, and will always furnish a proof if requested, or if it is thought that any particular member is specially interested in the subject.

The gravest offender of all the minor institutes in this matter is undoubtedly the Institution of Electrical Engineers. The fact of being a member or associate of the institute is no guarantee that the recipient of the honour is a *bonâ fide* electrical engineer. He may be interested in electrical engineering, say, by holding shares in some electrical company, or by keeping its books. In the management of the Institute, provincial members are altogether ignored. Practically they are told to pay their subscriptions, and accept with becoming gratitude the favours in the shape of the briefest of post-cardial announcements, *Transactions* at uncertain times, and invitations to dinner at very high prices. And the cream of the joke lies in the fact that a non-member can get all these, and be better served than a member. He can buy the *Transactions* at considerably less than the amount of his subscription. He can attend the meetings, if he likes, just as a member can. He can speak at the meetings, and he often does, to the exclusion of members. He can see in the weekly technical press, some days before he would receive his own brief notice were he a member, when meetings are to take place, and the subjects to be discussed. He can dine, too, when members do, if he likes to pay and go with a member friend.

The writer of this article, who has been watching the progress of the Institution of Electrical Engineers for some time past, because he hoped to see it come out of its present subordinate position, and take its place among the leading institutes, was much struck with the following. About a year ago he had occasion to complain of what he considered an act of discourtesy towards him. He was referred to the rules, and that was all that anyone could or would say or do. The idea of a provincial member complaining of discourtesy looked really too ridiculous, though he had belonged to the Institute for 16 years or so. In further reply, the writer gave it as his opinion that if members generally were treated in the same manner, the Institute would go down in numbers. He was told not to be at all afraid of that, as at least 200 new members were being elected annually. Not many months after, a proposal was suddenly made to increase the rate of subscription to new members. In the writer's opinion this was a step backwards. If anything, openings ought to be made to cover everyone who is *bonâ fide* working on some branch of electricity, so that the Institute may acquire the power that comes to any body which can speak in the name of the whole of those following a certain calling. The idea of a member whose own subscription it was not proposed to increase, and a country member, too, raising objections seems to have tickled the Council immensely. However,

there was a complete answer — a financial one. The Institute's revenue was not sufficiently in excess of its expenditure, and there seemed to be no means of retrenchment. Country members had stood a lot, but it might be supposed they would object to being done out of their notices, brief as they were, and of their *Transactions*, late as they come. London members could not be expected to give up anything. One might as well become a country member at once. Of course, this was not told the writer; he surmises it, as the fix seemed such a difficult one. But he ventured, like Oliver Twist, to ask for more information. In his opinion it seemed odd that with an increasing membership, and with country members so persistently ignored, that the proportion of revenue to expenses had declined. However, once more a complete answer was forthcoming. There were so many withdrawals from the Institute that it was absolutely necessary to put the subscription up.

Another thing, too, which struck the writer very forcibly when he attended a meeting some months since was the very large proportion of very young men, of which the audience appeared to be composed. The meeting-room was filled, but the men of full years, say, 30 and over, who were present were in a very decided minority. The Institute has also brought considerable ridicule on itself and has lost caste by the tone of its discussions. Striking personalities even find their way into the *Transactions*. Many speeches that are made are nothing more than advertisements of certain firms or certain companies. But the point the writer wishes to bring out, as forcibly as he knows how, is the fact that all which the minor institutes ought to do, and could do if properly managed, is being done far better, at considerably less cost and with profit to themselves, by the technical journals. The institutes dare not withhold their *Transactions* from these journals if they could. In fact, the favour, if any, is on the other side. To have their papers reproduced is to advertise themselves, that they are still alive, as nothing else can. And yet these papers produce, not only all the *Transactions*, but other articles upon important subjects, and valuable information in addition. And further, their columns are open to everyone who is interested in the science and can write intelligently.

It is well known that electric engineering will be *the* branch of engineering of the future *par excellence*; that it already threatens to eat up its older brethren, as Pharaoh's lean kine did; and that every year brings increased possibilities and a larger field. Surely, it is not too much to ask that those who are guiding the Institute which should be representative of the whole body of electrical industry should rise to their position, and should prepare to lead towards the great future we are all hoping for.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

III.—WORK AND HORSE-POWER.

(Continued from page 401.)

GAS AND OIL ENGINES.

Those who visited the Electrical Exhibition held at the Crystal Palace during the first half of 1892 and who inspected the Machinery Department, must have been surprised to see the great number of gas engines that were at work—gas engines of all sorts and conditions. There probably has never been such a display of gas engines of various types (more than a dozen) before; at all events, not in England.

The advent of the gas engine could not have occurred at a more opportune time than in conjunction with the advent of electric lighting; the one has to great extent furtheranced the adoption of the other, and *vice versâ*. The private electric light installations, such as in country houses, hotels, etc., called for a reliable source of small power which could be drawn upon at five minutes' notice, and did not necessitate constant individual attention. This want was supplied by the gas engine. On the other hand, it is safe to say that the adoption of electric lighting has been the means of considerably widening the field in which this kind of motive power can be used with advantage. The great number of gas engines of various types now invented is due to the expiry of patent rights in England of the fundamental principle of Otto's cycle, hitherto held by Messrs. Crossley Bros., and which expired in the summer of 1890. The idea of obtaining motive power by igniting explosive gases dates back to the seventeenth century, when Robert Street, in 1794, was the first to make a practical gas engine having a cylinder and a piston. After this, numerous attempts and inventions were made to produce a gas engine that would be of practical and commercial value. But it was not until the year 1876 that the internal-combustion engine assumed a shape that made it at once a reliable source of motive power and a sound commercial success. This important improvement was made by Dr. Otto, whose name is now famous all over the world. The manufacture of these engines was taken up in England by Messrs. Crossley Bros., of Manchester, who have made great improvements in detail and mechanical construction.

The Otto Cycle.—The method in which Dr. Otto uses the gas, and the operations that take place in the cylinder of the engine, is known as Otto's "cycle of operations," and in order to understand how a gas engine works, it is necessary to know what the "cycle" is. The cycle of operations consists of four distinct operations. We will imagine the piston at the top end of the cylinder ready to make its forward stroke. Upon moving forward, the admission valve is opened, and a mixture of coal gas and air is drawn into the cylinder after the piston. When the piston reaches the bottom of the cylinder the admission valve is closed, the whole of the cylinder space in front of the piston being now occupied by a gaseous mixture. Upon the piston making its return stroke it drives all this mixture in front of it, and as it cannot escape it is compressed, so that by the time the piston has reached the end of its stroke the gas exists under great pressure. These two strokes of the piston, one forward and one return, constitute one complete revolution of the flywheel. The third operation now takes place—that is, the ignition valve is opened, and the mixture fired. The explosive force gives an impetus to the piston, which consequently travels forward upon arriving at the end of its stroke. The impetus given to the flywheel tends to carry it round past the dead centre, therefore the piston is urged to make the return stroke. At the moment of returning, the exhaust-valve is opened, and so the fourth operation consists of the piston driving out before it all exploded mixture, which now escapes by the exhaust port. Upon arriving at the end of its return stroke the admission valve is again opened, ready to admit a fresh charge of gas and air, and so the first operation is ready to be repeated. These four operations constitute a complete cycle, and can be stated thus:

A. Admission of gaseous mixture.
B. Compression " "
C. Expansion " "
D. Exhaustion " "

The cycle produces two complete revolutions, so that an explosion takes place and an impulse is given to the piston once every two revolutions, or during every alternate forward stroke of the piston.

Combustion in the Cylinder.—When a gaseous mixture explodes, it means that the gases burn with very great rapidity, so that explosion signifies rapid combustion.

The intensity or force of an explosion depends on a number of circumstances, such as the composition and nature of the gases, their pressure, etc. The duration of an explosion is the time that elapses between ignition and the maximum pressure produced. The shorter this time is the more powerful and effective is the explosion. Further, this maximum pressure occurs, and therefore the explosive character ceases, when one-half of the total heat of combustion has been evolved. A rich gaseous mixture explodes more rapidly than a poor mixture. After ignition the whole of the heat of combustion is not evolved at once, but takes place gradually, combustion taking place more slowly the nearer the end is reached; for if this were not so, the shock would be so great that enormous pressure and strain would

be put upon the mechanism of the engine. Combustion and evolution of heat thus goes on throughout the whole length of the piston stroke. By making the combustion gradual in this manner, a more even and steady pressure is given to the piston. An explosion every revolution gives a more steady-running machine than one in every other revolution.

Efficiencies.—The power and efficiency of a perfect heat engine can be measured by the absolute temperatures between which it works. When mechanical energy is produced from heat energy, it must always be accompanied by the annihilation or disappearance of an equivalent amount of heat energy, and this is shown by the fall of temperature which takes place in the heat-producing body. The higher and lower temperatures between which the fall occurs are called the "limiting temperatures," and the greater the difference between them the greater is the power produced. From this it is clear that when a body does work it must lose heat or fall in temperature, just as a body of water, in order to do work, must fall from a higher to a lower level, or a current of electricity from a higher to a lower potential. The limiting temperatures indicate the "efficiency" of the perfect heat engine, and the greater the difference of temperatures the greater the efficiency. Take the case of an ideal steam engine, where the temperature of the steam on entering the cylinder is, say, 200deg. C., and on leaving is 50deg. C. The fall in the temperature measures the work that is done on the piston. First, however, the temperatures must be reduced to absolute temperature. Absolute temperature is – 273deg. C.—that is to say, a body at that temperature is supposed to have so little heat that it is fixed theoretically as zero; so that a body at the ordinary temperature of 0deg. C. is really at 273deg. C. absolutely.

The limiting temperatures absolutely are then (200 + 273) – (50 + 273) or 473 – 323.

Let the higher temperature be T,
" lower " t,

then the efficiency of any heat engine working between these two limiting temperatures can be calculated by the general formula—

$$\frac{T - t}{T} = \text{efficiency.}$$

Applying this particular example, we have—

$$\frac{473 - 323}{473} = \text{efficiency} = \cdot 31.$$

Hence an engine working between these temperatures can only utilise about one-third of the heat supplied to it, and this is the utmost efficiency, theoretically, that can be got out of it, judging it an ideal or perfect engine.

The steam engine in use to-day is very far from being perfect, and heat is wasted to a great extent, as the best made can only utilise 20 per cent., and if judged from the coal consumed the total efficiency is only 10 per cent., since 50 per cent. is lost in the boiler.

In a gas engine the cylinder is the furnace of the engine, and the fuel and the motive force are one and the same, whereas in the boiler the fuel is coal and the motive force steam.

According to Prof. Robinson, in his authoritative work on "Internal-Combustion Engines," the temperature of the exploding gases in the cylinder of a gas engine can be taken at about 1,600deg. C. just after the moment of ignition, although it is very difficult to find out what is really going on inside the cylinder, there being so many disturbing elements to contend with. As the gases burn and expand, the temperature falls, until just at the end of the stroke, when they are leaving the exhaust port, the temperature is about 400deg. C. This gives an ideal efficiency of

$$\frac{1{,}873 - 673}{1{,}873} = \frac{1{,}200}{1{,}873} = \cdot 64.$$

Like the steam engine, a great amount of this heat is lost in practice; the exhaust gases carry off nearly one half of the total heat available, while the water-jacket carries off another quarter. The following proportions are given by Prof. Robinson as to the probable way the heat is distributed:

Heat utilised by piston	23 per cent.
" carried off by exhaust	27 " "
" " " water jacket ...	50 " "
Total heat of combustion =	100

Comparing the total efficiency of the steam engine with that of the gas engine, a steam engine utilises, say, 10 per cent. of the heat evolved by the coal; a gas engine utilises, say, 20 per cent. of the heat evolved by the coal gas. So that a gas engine is twice as efficient as the steam engine. A very good steam engine uses, say, 2lb. of coal per brake horse-power hour, this being the utmost efficiency practicable; 1lb. of coal, when burnt, will evolve 14,500 heat units; 2lb. = 29,000 units. In a large-sized gas engine it may be taken that the consumption of gas per brake horse-power per hour is 22·5 cubic feet; 30 cubic feet of gas weigh 1lb., and evolves 20,000 heat units, 22·5 cubic feet of gas weigh ·75lb., and evolves 15,000 heat units. Therefore the gas engine only requires 15,000 heat units to produce 1 b.h.p., whilst the steam engine requires 29,000, or close on double.

The efficiency of the mechanism of a gas engine—that is, the ratio of the indicated horse-power to the brake horse-power—is high, and about similar to that of a steam engine. On an average it may be put down that the brake horse-power is 85 per cent. of the indicated horse-power or that 15 per cent. is lost in friction of the moving parts, etc. One pound of good anthracite coal will yield about 4·5 cubic feet of coal gas, so that in fairly large engines the consumption of coal per brake horse-power per hour is, say, $\frac{22 \cdot 5}{4 \cdot 5} = 5\text{lb.}$

The heat energy obtained from burning the gas obtained from 1lb. of coal is therefore $\frac{20{,}000}{30} \times 4 \cdot 5 = 3{,}000$ heat units, or only one-fifth of the heat energy obtained by burning the coal.

The Water-Jacket.—The great temperature attained by the exploding gases, about 1,600deg. C., and the great amount of heat that is absorbed by the walls of the cylinder, would have a most injurious effect on the cylinder, causing overheating, expansion, etc., and preventing lubrication, etc., unless it were protected in some way for the purpose. The cylinder is enclosed in a water jacket, somewhat like a steam-jacket round the cylinder of a steam engine; through this water-jacket a current of cold water is caused to circulate. To obtain a continual circulation of water a capacious tank is fixed as close as convenient to the engine, and at a level of, say, 6ft. above the floor. A pipe leads from this tank into the bottom of the water-jacket, and another pipe leaves the top of the water-jacket and returns to the water-tank. The water has thus a free passage round the walls of the cylinder, the great heat from which raises the temperature of the circulating water. The circulation is produced by the water leaving the jacket hotter than it enters it. In general, the water leaving the jacket ranges from 40deg. C. to 60deg. C., according to the type of engine, and the water entering should be a little above the temperature of the atmosphere. A suitable tank is always fixed up by the supplier of the engine.

Consumption of Gas.—It may be taken that a medium sized gas engine—say, 14 b.h.p.—will consume about 25 cubic feet per brake horse-power per hour, working at full load, when the gas is supplied at a good pressure, and is of a good quality. In districts where the gas is poor in its heat-giving properties and below the proper pressure the consumption will be greater. This is often the case in country districts or about small towns. The consumption of gas in a gas engine may be taken to vary inversely as the power of the engine. Taking a 14 b.h.p. as a medium and standard, we may put down 25 cubic feet per brake horse-power per hour at full load. Now as the power rises so the consumption of gas falls, and as the power falls so the consumption rises. The following tabulation will serve as a guide, although the figures given are only approximate, and may be slightly

higher or lower, according to the type of gas engine used, no particular gas engine being specified.

TABULATION III.

Brake horse-power	3	6	9	[illegible]	22	35	72
Cubic feet per b.h.p. per hour..	37	[illegible]	27	25	22	20	17

It is not advisable to work a gas engine up to its utmost power unless circumstances demand it; a fair margin should always be allowed. This is particularly so when it is working electric lights, because if an explosion is missed, as often happens, the engine becomes overloaded, and tends to pull up, and very often it must be eased before it can recover itself. Lately, gas engines of very large power have been put on the market, and with great success, sizes of 200 i.h.p. being manufactured. Engines of above 80 i.h.p. or about that power are made with twin cylinders. The very small sizes, say from 1 b.h.p. to 6 b.h.p. are made both vertical and horizontal, the vertical design being very useful where floor space is limited.

Advantages of the Gas Engine.—Gas engines are greatly in demand where small motive power is required, and their advantages on this score are not to be denied. They can be put down anywhere where a supply of gas is to be had, can be started in 10 minutes, stopped in one minute, and require very little attention—very different from the constant watching which a boiler and steam engine necessitate; no flue or chimney shaft has to be built, and the engine, having its furnace in its cylinder, occasions no dirt or trouble in keeping in order. It is not necessary to have a man on purpose to run a gas engine, except very large sizes, or where the plant is one of great importance, say in a theatre, etc., where great, if not serious, inconvenience would occur to the public in the event of anything going wrong. In country houses where they run an electric plant by a gas engine, the plant is usually placed under the care of the gardener or other ground man, and who only needs to look in every hour to oil up and see that everything is right; in a number of places the lights are run from accumulators or storage batteries, the gas engine running only during the day time to charge them with the dynamo, the lights being disconnected. Special oiling arrangements can be supplied with these engines for this kind of work, so that they can be run for 10 or 12 hours without attention.

Running Cost of Gas Engines.—An investigation will now be made respecting the probable cost of running a gas engine; one of 35 b.h.p. will be chosen, so that it will be about the same size as the 40-b.h.p. steam engine, whose cost was given on page 401, the maintenance cost being divided up in the same way as with the steam engine. A comparison of costs between gas and steam power can thus be made. The outlay for a gas engine yielding about 35 b.h.p., including foundations, water-tank, pipes, and fixing in working order, may be put down at £280. The running cost will be divided into two parts, as was done when estimating the running cost of a steam plant.

Therefore we have

Large Gas Engine of 35 b.h.p.

A.—INVARIABLE COSTS.

	B.H.P. per annum.	B.H.P. per hour.
Interest on outlay, £280 at 4 %	£0 6 4	·025 penny.
Depreciation ,, ,, 7½%	0 12 0	·048 ,,
Repairs ,, ,, 5%	0 4 8	·018 ,,
Attendance, two hours' time per day	0 8 7	·034 ,,
Total	£1 11 7	·125 penny.

B.—VARIABLE COSTS.

20 cubic feet of gas per hour for 3,000 hours, gas being 2s. 9d. per 1,000 cubic feet	£8 5 0	·66 penny
Oil, water, waste, and sundries	1 0 0	·08 ,,
Total	9 5 0	·74 penny

Giving total cost per brake horse-power per annum = £10. 16s. 7d
And ,, ,, ,, ,, hour = ·865 penny

As with the steam engine, let the gas engine only work for 1,500 hours per annum; when used for running electric lights from dusk to 10 p.m., another comparison can then be obtained respecting running costs, the working hours in this latter case being only half the former. The first part (A) of the cost will remain constant, while the second part (B) will vary in proportion; since 1,500 is half of 3,000, therefore the variable costs will be £9. 5s. ÷ 2 = £4 12 6
and the total will be £4. 12s. 6d. + £1. 11s. 7d. = 6 4 1
Giving the cost of 1 b.h.p. per annum .... = 6 4 1
,, ,, ,, ,, ,, hour............ = 0 0 1

Following up the comparison of cost of gas *versus* steam, we will now work out the probable cost of a 9-b.h.p. gas engine, this small size being taken to compare with the 10-b.h.p. steam engine, allowance being made for the lower efficiency, as was done with the small steam plant. The outlay for a 9-b.h.p. gas engine, high speed, and designed for electric light plant, may be put down at £160, everything complete. The running costs being as follows, the engine working 3,000 hours per annum:

Small Gas Engine of 9 b.h.p.

A.—INVARIABLE COSTS.

	B.H.P. per annum.	B.H.P. per hour.
Interest on outlay, £160 at 4 %	£0 14 3	·057 penny.
Depreciation ,, ,, 7½%	1 6 8	·100 ,,
Repairs ,, ,, 3 %	0 10 8	·043 ,,
Attendance, two hours per day	1 13 4	·133 ,,
Total	£4 4 11	·333 penny.

B.—VARIABLE COSTS.

27 cubic feet of gas per hour for 3,000 hours, gas being 2s. 9d. per 1,000 cubic feet	£11 2 9	·890 penny.
Oil, water, waste, and sundries......	1 5 0	·100 ,,
Total....	£12 7 9	·990 penny.

So that total cost per brake horse-power per annum = £16 12s. 8d.
And ,, ,, ,, ,, ,, hour = 1·33 pence.

This is just over 50 per cent., or half as much again as the cost per brake horse-power of the large gas engine; or by spending two and one-half times as much per annum for the large plant, four times the power can be obtained, since 40 × £10 = £400, and 10 × £16 = £160.

Letting the small gas plant run for 1,500 hours per annum, the figures work out as follows: We have £4. 4s. 11d., which remains constant, and £12. 7s. 9d., which must be divided by 2, because the value of B are in proportion to the hours. So the total costs will be £4. 4s. 11d. + £12. 7s. 9d. ÷ 2, or £4. 4s. 11d. + £6. 3s. 11d. = £10. 8s. 10s. per brake horse-power per annum, or ·4 penny per brake horse-power per hour.

When motive power is required for running electric lights on business premises, the time from dusk to 10 p.m. (which is 1,456 hours per annum including Sundays, and 1,248 hours per annum excluding Sundays), is in most cases too long, and calculations for much shorter hours might be acceptable. From dusk to 8 p.m., including Sundays, means about 742 hours per annum, or 636, excluding Sundays, and from dusk to 8.30 p.m., excluding Sundays, signifies close on 786 hours per annum. Taking half of 1,500, we have 750, and this number of hours will be near enough to judge of the cost of running from dusk to 8.30 p.m., excluding Sundays.

The results are as follows, 750 hours running:

Large steam plant per b.h.p. .. ... =	£6 5 0 per annum, and =	2·00d. per hour.
Small steam plant per b.h.p. ...... =	14 17 3 per annum, and =	4·75d. per hour.
Large gas plant per b.h.p. . ..=	3 17 10 per annum, and =	1·24d. per hour.
Small gas plant per b.h.p. ...... =	7 6 10 per annum, and =	2·35d. per hour.

(To be continued.)

Prescot and Knowsley.—The cable for the electric lighting of Prescot and Knowsley Hall has now been completed by the Insulated Wire Company, of Prescot. The generating plant is situated at Prescot. The mains to Knowsley Hall, over three miles distant, are concentric. There are two of these mains, each capable of supplying 1,000 lights, so that if any repairs are wanted on one main the supply will not be interrupted. With regard to Prescot it is proposed to place 12 arc lamps in prominent positions in the town, and these can be supplemented when required by incandescent lamps. A ring of three mains surrounds the town, one being for private supplies, the other for public lighting, and another for shops and factories. The Prescot Watch Factory is to be lighted with 1,500 lights, and other arrangements are in negotiation for the lighting of various residences in the district. The work has been carried out under the direction of Mr. S. V. Clirehugh, engineer to the company.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE IV.

(Continued from page 411.)

Now, as an example, I will mention the case of the city of Edinburgh. There it is possible to use the heights which surround the town for collecting the water. In the immediate vicinity of that town there is the hill known as Arthur's Seat, at a height of 800ft. above the sea. There is on this hill a loch already, called Dunsapie, which holds water enough to supply 1,000 h.p. for two hours. Anyone who is conversant enough with central station work will see that here there is the means of supplying sufficient power for doing the work of a large central station—in fact, driving one central station by means of the water power which could be derived from that reservoir; but with the utmost facility a dam can be built across a gully which there is near the summit of the hill, giving us a far greater height, and this dam would cost but little, owing to the natural construction of the hill; it would be invisible from all parts surrounding Edinburgh, save only in one direction, and even in that it would not be on the sky line, and would not be an injurious feature in the landscape, whilst to those who go up to the summit to enjoy the view, the lake which would be formed would be an extra attraction. There is really nothing in the beautiful features of the place to prevent that being done, and thus the amount of power which could be stored would be fully doubled. For working a station which requires the maximum of, say, 1,000 h.p., we do not require an average in many cases of more than about 150 h.p. What, then, we should have in this station would be engines and boilers for 150 h.p. continually working day and night, from week's end to week's end, employed in pumping water up through pipes to this reservoir on Arthur's Seat. In connection with these pipes, at or near their lowest part we should have turbines driving dynamo machines, for the distribution through the town. Instead of being obliged to have engines and boilers of 1,000 h.p. we should have them of only 150, thus saving an enormous amount in capital expenditure. If we do not require to build a dam, as we do not in the first instance, using the Loch Dunsapie which is there, the only serious item to consider, to be put against the boilers, is the pipes. These would come to something like £2,000, but the saving in capital expenditure on the whole is very great. But it is not only the saving of capital expenditure which is important; it is the annual saving in the coal bill. The pumping up of this water by an engine perfectly continuously can be done in the most economical manner that any work with steam engines can be done; whereas, on the contrary, we know that in central station work for electric lighting we have one of the most uneconomical methods of using coal possible. We can get 1 h.p. available on the turbines, including the losses in pumping up and the losses in the turbines, for certainly very little over 3lb. of coal per horse power per hour used in the boilers; whereas, in many central stations, as you know, they are going up to 10lb., 15lb., or even more of coal per horse-power per hour. There is then undoubtedly a most enormous saving in fuel besides the saving in capital expenditure, and for these reasons, wherever such a system is available, it will be desirable to adopt it rather than to put down the whole plant necessary for generating the maximum current which may ever be required. I worked out this pretty fully in the case of Edinburgh for my own satisfaction, and have already brought the matter before the authorities there, and I hope to see some such scheme adopted, not only there but in many other towns also where equal advantages are offered. In working out the figures I may say that the actual expenditure is very little more than half what it would be if we were putting down steam plant for the whole work, and the savings which are effected in attendance and fuel are, even when we are using coal for generating steam, very great indeed. It saves about one third of the expense, not including of course the expense of distribution of electricity, and so forth.

* Cantor Lectures delivered before the Society of Arts.

If I had to be contented with simply what I have told you up to the present moment, such a scheme would be of the utmost value in cases where it is applicable, but there is another source of economy which can be introduced, and for which this system which I have advocated is perfectly suitable. This leads me to the part of the subject to which I wish to draw your attention this evening, and that is the employment of destructors for utilising the refuse in towns—the ashbin refuse, which at present costs an enormous sum of money to be got rid of, and which, in many towns, is simply tipped in the outskirts, and becomes a source of disease and danger especially when the town expands, and building operations commence in the region which has been used as a tipping ground. The whole question of the disposal of town refuse is one of importance. It is one to which, I need hardly say, electrical engineers, as a general rule, have not paid much attention. I daresay there are comparatively few here who have really gone into the question of the use of destructors, and I should not be surprised if there are some present who have hitherto been ignorant of what a destructor was; in fact, a very well-known electrician last week, after I announced that I was going to speak about destructors, and the considerable importance that I attached to them, came and asked me, after the lecture, what it was I was going to talk about.

Several years ago, when I was advising the Vestry of Paddington about the electric lighting of their parish, I found that they were in a serious difficulty in dealing with their ashbin refuse, and I was led immediately to see the importance of studying the whole question. I then made a personal inspection of most of the destructors which were then in use, and I was so enormously impressed with the importance of the subject that ever since then I have neglected no opportunity of seeing the work which is being done in this direction in the different towns.

Let us see what the problem was that Paddington had to face. Every year they collected something like 20,000 tons of refuse of this character, and since the population of Paddington is 112,000, we may assume generally that something like this proportion exists in nearly all towns. It so happens that the proportion of ashbin refuse to population does not vary very much with the different towns. Now, it will strike you, as it has struck me as a very wise provision of Nature, when I tell you that if this refuse were properly burned, and if it were used in the most economical way, it would be found that (assuming the proportion of lighting required for such population to be, as has been very generally assumed, one lamp per head) the amount of refuse provided by any population is almost exactly as much as is required to supply the illumination by means of the electric light to that same population.

Now let us see what this refuse is which is collected every year in Paddington. Out of every 10,000 tons we find that ashes constitute 5,260 tons, breeze or cinders 2,880, what is known as soft core—viz., animal and vegetable refuse—1,420, hard core, which is pottery and that sort of stuff, 290, actual coal 15 tons, bones 25 tons, rags 42 tons, iron 35 tons, brass and pewter 3 tons, white glass 7 tons, and black glass 23 tons. These are the materials that have to be got rid of. I have given you these figures as I found them at Paddington, because Paddington is more able to give accurate information on the subject than almost any place I know of, because in Paddington, instead of simply taking away the refuse and dumping it somewhere or other, as is done in many towns, they found it was more economical to sort out the different materials in this way, and sell some of them for different purposes. They were able to get a sort of price for a great many things. Coal always had its use, and breeze and ashes could be sent to the brickfields, and they were able to recoup themselves to a certain extent, so that really the actual cost of getting rid of it in the parish of Paddington was only about £1,000 per annum. In other places it is very much more, but in any case the manner of getting rid of it was bad. There was a large proportion of stuff which could not properly be rendered harmless, but which had to be disposed of in some way. The quality of the refuse varies with the different towns. For example, in this you see there is no sludge of the streets, and no other objectionable

matter which may be found in other places. In Manchester, for example, out of 10,000 tons there are 6,450 tons of ashes and excreta, which are collected in pails, dust and cinders 3,455 tons, fish and bones 15 tons, dogs, cats, hens, rabbits, etc., 5 tons, boots, rags, hats, paper, etc., 5 tons, vegetable refuse 5 tons, glass, pottery, bricks, etc., 60 tons, old iron and tinware 5 tons. That makes the 10,000 tons. In addition to that, they have to dispose of slaughter house refuse and market refuse, and street sweepings, amounting to 2,900 tons, in addition to every 10,000. The aggregate quantity of burnable material is 70,000 tons. It is found that the quantity of coal which is collected in the ashpit refuse varies with different times of the year, and with different districts. It is more in the richer residential districts, and it is also more in winter. In summer there is more vegetable stuff, which is less combustible, and there are some places in which the ashes are exposed to the rain, in which case the combustibility is affected. But then see another wise provision of Nature—the coal and cinders are more frequent in winter, when we want most light, and vegetables are less frequent then, and they are less combustible materials.

The history of the use of destructors is comparatively modern, and the very first ones that were attempted were not very successful. The cause of their failure was almost altogether due to insufficient draught, and in almost all cases where a great improvement has been made in them, it has been by the introduction of greater draught. In the first destructors the furnace was fed from the front, just as the ordinary furnace of a boiler is, but that has been completely done away with now. During the last 20 years, one type of destructor has been most generally used—that is, the type known as Fryer's destructor—which has been made by Messrs. Manlove, Alliott, and Co., of which I shall have more to say later on.

Fig. 1.

The first destructors which were put up on any scale were in Water-street, Manchester. Eight furnaces were put up, and these were the first that were any practical success. They consumed 28½ tons each per week of 5½ days. They were 8ft. 6in. by 4ft. 3in. wide, and 6ft. 3in. high from the firebars up to the crown of the arch; 5ft. of the length was occupied by firebars, and 3ft. with the hearth. There was a bridge at the back, and a descending flue down into the main flue for carrying off the gases.

The next place that was furnished with destructors was the Montague-street Wharf, Birmingham. These destructors have been in use for a long time, but they have been combined with the process employed there of converting excreta into profitable manure for agriculturists, and consequently the efficiency of the destructors has been considerably impaired. It was necessary there to keep up steam for the treatment of the excreta, and steam was got up from these furnaces by putting the boilers directly over the furnace. In consequence of this, the combustion is very imperfect. The large cooling surface of the boilers impedes the combustion in an effectual degree. In most cases where boilers have been used to generate some steam, the boilers have been put away, and after the gases have passed through the flue they then pass by the boiler, and the error has been in the opposite direction. At Birmingham the fault is placing the boilers on the furnace, so that there is no proper combustion; in many other places, take Southampton, for example, as a notable case, the boilers are put in a place where they cannot benefit from the maximum heat.

After these destructors had been introduced, the Fryer destructor came into more general use. Fig. 1 shows this destructor. The furnaces there are 9ft. long, 5ft. wide, and covered by a firebrick arch 3ft. 6in. high. The furnace has an inclination of 1 in 3, 4ft. of the bottom being a firebrick hearth, and the other 5ft. of firebars. The furnaces are arranged in two long rows, back to back, with a large flue underneath and between the rows, as shown in section in the diagram; and the air is admitted beneath the firebars. At its upper end the furnace is divided in two longitudinally by a short vertical wall. On one side of this division the hearth is inclined at a greater angle than the rest, as shown in the left-hand furnace on the diagram, and immediately over this is the opening through which the refuse is shovelled down, after being tipped over on the top from the carts which carry it, the hole being shown covered by a flat cover. On the other side of the dividing wall is the opening to a flue leading from the furnace to the main flue, as shown in the right-hand furnace on the diagram. Each furnace then has two outlets at its upper end, side by side, through one of which the refuse is fed from above; the other forming the exit through which the products of combustion pass to the main flue. Besides these there is, in a few of the furnaces, another hole right over the hottest part of the furnace (shown in the left-hand furnace on the diagram), which is generally covered, but can be opened when required. This hole is usually called the mattress-hole, and is used for putting in infected bedding and other material, such as carcases and other slaughter-house refuse, and other such like matters which have to be utterly destroyed. The main flue is sometimes made extremely large, so as to allow dust to settle, and baffles are sometimes introduced into it to increase the facility of the dust settling. Sometimes at the end of the flue there is a very large chamber put for the same purpose, through which the gases pass before entering the chimney. These are the chief points in connection with the Fryer destructor.

One of the chief defects of this destructor is that it is possible for the air which is admitted to blow towards the flue and carry half burnt stuff down into the flue. But the danger is not only from half-burnt stuff being carried down, but there is also another serious point—viz., that the fuel which is at the upper end of the furnace is, of course, being heated up by the flames in the furnace, and consequently giving off injurious and most objectionable gases at that comparatively low temperature, and instead of being burnt in the furnace they may be carried over into the flue immediately with the utmost facility, and become a source of great annoyance to the neighbourhood. In such a type of destructor there are always cases where objectionable and offensive fumes are perceptible, and not only objectionable smells, but unburnt material, consisting generally of a kind of scaly, shiny slag, in minute filaments, is seen to fall in the neighbourhood of the destructor, because this type of furnace does not allow of its being thoroughly burnt. I need hardly say that the higher the temperature in a furnace the better is the destruction of material, and not only is it desirable to have a high temperature, but also to have all the gas passing over that part of the furnace which has the highest temperature. I might give a considerable amount of further instruction from the study of many destructors which have been put up, but I will only mention one appliance which has been built to several destructors, and that is what is called a cremator. It was first introduced by Mr. Chas. Jones at Ealing. It consists of a furnace, in which coal is generally used, and over this furnace all the gases are passed before they go to the chimney, in order to burn the organic matter of the gases which have been allowed to pass through the furnace. I can only say about cremators—although I have seen a great many built—that they are very seldom to be seen at work except when there is a deputation coming to examine them, because the cost of working them is far too great.* If anything in the shape of a cremator were to be used at all, I would suggest that the gases ought to be passed a second time through the furnace, from under the firebars.

* Mr. Jones informs us that this is not true at Ealing, that the cremator at Ealing has been burning night and day for seven years, except, perhaps, a fortnight in the year for repairs; and that the additional cost is quite immaterial.

Since there is 80 per cent. of air in the gases that come out of the chimney, it is perfectly clear that we could get good combustion in a furnace, if those gases were fed under it.

(*To be continued.*)

TRADE NOTES AND NOVELTIES.

TEMPERED COPPER.

As copper in its various forms constitutes a vital material of all electric apparatus, and especially that of dynamo-electric machinery, all improvements relating to the manipulation of copper may well claim a prominent position of interest to elec-

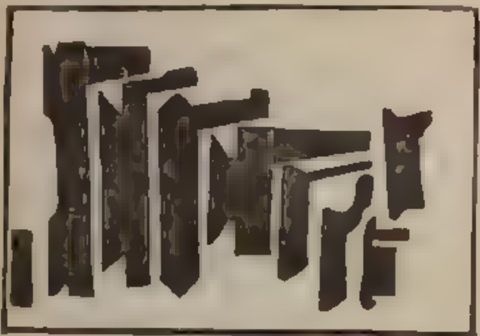

Fig. 1.

trical engineers. The solution of the problem of discovering a process by which the life of this important metal could be prolonged, has much occupied the time of investigators. Mr. Alner Thomas's investigations led him, first, to a method of casting pure copper without alloys of any kind, and free from blow-holes; and, second, to a method by which the copper so cast can be hardened sufficiently for all mechanical uses, and imparted a strength equal to that of ordinary steel, or, if desired, made as malleable as wrought iron, and capable of being welded or forged into any desired shape by any blacksmith. A company was formed, and Mr. G. Berend, of 61, Fore-street, has been appointed representative here. The company devoted a great deal of their attention and a large part of their works entirely to the manufacture of commutator segments and brushes; for in spite of the many attempts which have been made to supersede the employment of copper subjected to wear in electrical apparatus, the fact remains that at the present time no real substitute is available. Their metal, the Eureka Tempered Copper Company claim, combines these peculiar qualities which enables the commutator bar to withstand the action to which all surfaces transmitting heavy electric currents are subjected.

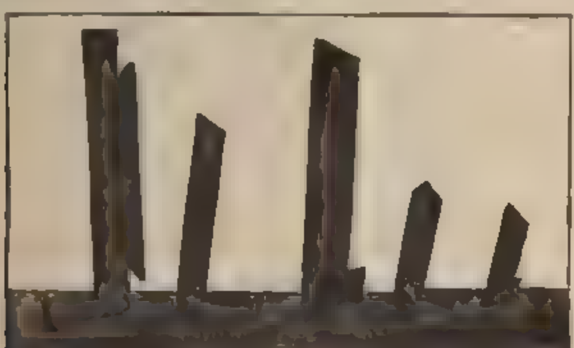

Fig. 2.

In Figs. 1 and 2 are illustrated a variety of commutator segments employed in various types of machines. Fig. 3 shows two well-known types of commutators, that to the left being the usual type employed with the Gramme and Siemens type of armature, and that to the right a Brush commutator. But there are still more important surfaces subject to wear on the dynamo—namely, the brushes, and in this direction also the metal has been used. Fig. 4 shows various types of brushes, from those with fine slits, up to the type embodying almost a solid construction, adapted to various types of machines. These brushes partake of the same nature as the commutator segments, in their wearing qualities, in toughness, as well as their conductivity.

The large wear met with in some of the practical details of electric railway work has also developed several important applications for tempered copper. Among these we may mention its employment in the gears employed to transmit the power from the motor to the car axle, and also for trolley wheels to take the current from the overhead wheel; its peculiar toughness gives it not only a long life, but the anomalous structure of tempered copper largely reduces the noise, which is so noticeable and disagreeable a feature in steel pinions. In the case of the Eureka tempered copper trolley wheels, its wearing qualities have also largely reduced the difficulties encountered by this necessary adjunct to electric railway work. Numerous tests have shown tempered copper to consist of copper 99·981 per cent. pure, with a tensile strength of 64,000lb. per square inch, and a compression strength of 189,000lb. to the square inch. A test made a short time ago by the Austrian Government Industrial Department at Vienna showed a higher tensile strength than many of the steels which had been tested there. Wire made from tempered copper is being largely used for all purposes where great strength is desired, and its purity renders its conductivity far greater than that of copper alloys. Its use for telegraphy and telephony, especially long-distance telephony, in the States is rapidly increasing.

Fig. 3.

The chemical analysis which has been made by Dr. F. A. Genth, of Philadelphia, of tempered copper in various forms, confirms that it is pure copper without alloy, and that no chemicals are added in the process of tempering.

the Eureka Company, but untempered; and B, tempered, being made after that bar had been tempered.

NEW COMPANIES REGISTERED.

Elieson Accumulator (British Patent) Syndicate, Limited.—Registered by Arnold Cunliffe, 6, Great Winchester-street, E.C., with a capital of £12,000 in £1 shares. Object: To acquire from C. P. Elieson certain patent rights relating to improvements in electric accumulation, in accordance with an agreement, particulars of which are not given; generally, to carry on business as manufacturers of and dealers in electrical apparatus and apparatus of every description. There shall not be less than three nor more than seven directors, the first being the first signatories to the memorandum of association. Qualification, £100. Remuneration to be fixed in general meeting.

BUSINESS NOTES.

Portsmouth.—The foundation-stone of the central station was laid yesterday.

Glasgow.—Electric light has been introduced into the large warehouse of Messrs. Wylie and Lochhead, in Buchannen-street, Glasgow.

South Africa. — Electrical pumping machinery has been ordered for the Durban-Roodepoort and Main Reef Companies' properties.

Fiume.—The authorities of Fiume, Italy, invite tenders for the construction and working of an electric tramway for passengers and goods.

Electric Heaters.—A system of electric heaters specially adapted for conservatories is being brought out by the firm of Olivet et Cie., Geneva.

Aberystwith.—The experiment with electric lighting for the Aberystwith Corporation has been satisfactorily carried out by Messrs. A. Hall and Co., of Liverpool.

West India and Panama Telegraph Company.—A dividend of 6d. per share is recommended by the Board for the first half of the current year, carrying forward £3,704.

Change of Address.—The offices of the Epstein Electric Accumulator Company, Limited, have been removed from 34, Cannon street to 19 and 21, Queen Victoria street, E.C.

Indo-European Telegraph Company.—The Board have declared an interim dividend at the rate of 5 per cent. per annum for the half year ended June 30 last, payable on the 1st proximo.

Wigan.—At a meeting of the Wigan Gas Committee last week, it was decided that application be made in the proposed Bill for powers to borrow the sum of £30,000 for electric lighting purposes.

Electrical Omnibus.—The *Daily Telegraph* of Thursday has a long article on electrical omnibuses, and announces that Mr. Radcliffe Ward's 'buses may be expected to be running in London within a fortnight.

Penarth.—The residence of Mr. Thomas Morel, Penarth, is being fitted throughout with electric light by Messrs. J. B. Saunders and Co., of Cardiff. An Otto gas engine, driving dynamo with accumulators, will be used.

York.—We understand that Mr. Crompton, desiring to resign his position as consulting engineer to the York Corporation in reference to the electric lighting scheme with a view to his firm being at liberty to tender, his resignation has been accepted.

Wrexham.—The local electric company at Wrexham is beginning to bestir itself, but there is considerable feeling in the district that the Corporation should take over the concession itself. The St. Pancras success is responsible for a good deal of this feeling.

Personal.—Mr. David Cook, manager, City of London Electric Lighting Company, Limited, who has for some months past fulfilled the duties of engineer as well as those of manager, has been formally appointed engineer and manager to the Company.

Anti-Sulphuric Enamel.—Messrs. Griffiths Bros. and Co. have a new specialty for the electrical trade, in the shape of a flexible shellac insulating varnish which does not crack or become brittle. This firm have a number of special preparations of use to electrical manufacturers.

Torquay.—Mr. Milne, one of the municipal candidates for Torquay, in addressing a meeting last Saturday, said the town was greatly in need of the electric light as the streets were very badly lighted, and he thought the water from the reservoirs could be utilised as motive power.

City and South London Railway Company.—The receipts for the week ending October 23 were £865 against £756 for the corresponding period of last year, or an increase of £109. The total receipts for 1892 show an increase of £1,212 over those for the corresponding period of 1891.

New Swindon.—The New Swindon Local Board have carried a resolution to make an offer to the local gas company. They had considered the cost of electric lighting, but it was found that it would cost £10,000 outlay to light a radius of two miles, and this was considered too expensive.

Chiswick.—At the Chiswick Local Board meeting last week the clerk, in his report, read a lengthy communication from the Board of Trade with reference to the contract with Messrs. Bourne and Grant for electric lighting in Chiswick. The consideration thereof was referred to the Electric Lighting Committee.

Bilston.—At the monthly meeting of the Bilston Town Commissioners, it was resolved that two more lights be placed in the Market Hall, and Mr. Hill remarked that as there had been another slight breakdown in the supply of electric light to the market, it would be necessary to obtain either duplicate machinery or accumulators.

Factory.—We had several enquiries some time back for site and buildings suitable for electric manufacturing shops. In our advertisement columns this week such an opportunity is disclosed, of a mill at Stamford hill, with ample steam power, 3,000ft. area of floor space, water and gas ready, and benches can be arranged suitable for manufacturing or experimental work.

Cambridge.—At the electric lighting works now in course of construction, an accident occurred on Tuesday morning by the falling of a quantity of brickwork in the furnace-room. Several workmen were more or less injured, and one, W. Burgess, of Chesterton, who was extricated with difficulty, had to be taken to the hospital, having sustained a severe scalp wound.

Torpedo Patents.—The whole of the patents and patent rights of Gibben's torpedo inventions are for sale, with building, show-room, mines, electrical table and apparatus, batteries, office furniture, and goodwill of the Submarine Mining and Torpedo Company, Limited, in liquidation. Application for cards to view to be addressed to Mr. F. Thorn, 37, Walbrook; Showrooms, Westcombe Station, S.E. Railway.

Steam Turbine Alternator.—We understand that Prof. Ewing has concluded his report upon this combination, and has obtained extremely interesting results as to economy. It is said that the result shows an economy equal to the best compound engine, or 15lb. of steam per indicated horse power, with 100lb. boiler pressure. The report is accompanied by curves, the whole of which we hope to give in our next issue.

Waterford.—The *Waterford News* exclaims against the policy of the Town Council, who, a few weeks ago, objected that they would not be able to raise the £3,000 necessary for electric light, are content to lose the £400 paid for the provisional order, the £400 a year saved over the cost of gas, and now ask for a large sum for a costly reconstruction of legal status as regards bridges and harbours of doubtful utility to the town.

Arlecdon.—At the Arlecdon and Frizinghall Local Board meeting, the question of the electric lighting was discussed, Mr. Boyd stating that the pressure gauge, which was ordered to test the pressure of their water supply, had not arrived yet, but he thought it would be there shortly. Circulars had been received from two separate firms, makers of the electric lighting apparatus, stating that they would be willing to undertake the work.

Extension of Premises.—Mr. R. W. Paul, of 44, Hatton-garden, E.C., has, owing to the increasing demand for the various electrical and physical instruments made by him, taken additional premises in Leather lane, to enable the firm to better cope with the larger trade orders. The new workshops have been fitted with steam power and modern machine tools, but the experimental workshops, test rooms, and office remain at Hatton-garden as before.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £3,486. The Board of this Company has decided that after placing £14,000 to the reserve fund and £6,610 10s. to the debenture redemption fund, the Directors would recommend, at the forthcoming meeting, a dividend of 3s. per share, free of income tax, being at the rate of 2 per cent. per annum for the six months ended June 30 last, carrying forward £1,662.

Burnley.—The Electric Lighting Committee of the Burnley Corporation are at present considering tenders for electrical plant for the lighting of the borough by the new illuminant. The central station for the generation of the electricity is to be situated in Aqueduct street, and the contracts for the buildings have already been let and the work commenced. Consumers will be required to provide their own lamps and fittings, and the wires will have to be fitted in accordance with special regulations issued by the Corporation.

Large Cargo Steamer.—The steamer "Samos," the largest vessel yet built on the Wear, and indeed the largest dead weight cargo vessel in the world, was successfully launched from the yard of W. Doxford and Sons, Limited, Pallion, before a large and interested concourse of people on Saturday. The vessel which is built of steel, and classed 100 A1 Lloyd's, is 465ft. long, 52ft. breadth, and 36ft. depth, has a gross register of 6,400 tons, dead-weight capacity of 9,250 tons on 25ft. draught, and gross displacement of 13,600 tons. The vessel is to be lighted throughout with electric light.

Edison Electric Company.—Mr. Philip S. Dyer, European agent of the Edison General Electric Company, writing from 34, Victoria street, Westminster, informs us that on account of the recent consolidation between the Thomson-Houston Electric Company and the Edison General Electric Company of America (now called the General Electric Company of New York), the European business of the Edison General Electric Company will be transferred on and after November 1st, to 7, Rue du Louvre, Paris, and the future business will be carried on from that office by Mr. E. Thurnauer, who, after that date, will represent in Europe the Edison General Electric Company, which company is part of the General Electric Company of New York.

Montevideo Telephone Company, Limited.—The report of this Company for the year ending July 31 shows a profit, including £470 brought forward, of £6,879, after providing for all working expenses in Montevideo and London, and after writing off £129 for proportion of preliminary expenses and £50 for depreciation of furniture at head office and in Montevideo. A considerable reduction has been effected in the general working expenses. In Montevideo the net decrease as compared with last year is £2,000, and in London £406. This latter item is almost entirely due to the reduction and final extinction of the managing director's salary, Mr. E. F. Powers having resigned this position. The Directors recommend that £5,000 be placed to reserve account, and the balance of £1,879 carried forward.

Chamber of Commerce.—At the meeting of the London Chamber of Commerce last Friday, after a good discussion, the

following resolution was ultimately passed. We have elsewhere commented upon the action of the section of the Chamber of Commerce, therefore we need do no more than give the resolution and the names of the committee appointed as follows: "That a sub-committee of the section be appointed to consider the whole question of the regulations of the Board of Trade, to confer with the Institute of Electrical Engineers, to suggest a course of action, to collect information, to submit witnesses, and to report from time to time to the section." The following gentlemen were afterwards appointed as the sub-committee: General Webber, and Messrs. Raworth, Ferranti, William Grey, Pott, Wharton, Garcke, Bayley, Erskine, T. Parker, Gordon, Swinburne, and Crompton.

Bolton. As a result of the visit of a deputation the Bolton Electric Lighting Committee have decided to recommend the system in use at Oxford as the most suitable one for Bolton. The Electric Lighting Committee will meet during the course of a few days to receive the final report of the sub-committee, and also to consider a number of tenders which have been sent in. The system proposed to be adopted will also be capable of driving the trams in the event of the Corporation deciding to take them over at the expiration of the lease next year. The accumulator system will be used. It is not intended to entirely substitute gas by electric light, but the committee consider themselves justified in proceeding with the matter, seeing that applications have already been received from shopkeepers and owners of large works in the town for over 2,000 16 c.p. lamps. The committee's report will be published.

Taunton. The following calculation of loss at the Taunton works is given by the *Somerset Express* ("open to amendment"). Taking Mr. Potter's statement that the net loss on the working for 1891 was £376, we have also Mr. Kapp's estimate of repairs and renewals as follows: Buildings, £40; steam and dynamo plant, £230; batteries, £100; street mains, £100; arc lamps, £20; total, £490. These are the figures of Mr. Kapp, the expert called in by the Town Council. This makes £836 on the wrong side. Nothing is yet put down for a redemption fund, though, from a business point of view, it ought not to be overlooked. Add to the amount already arrived at, £700 interest and instalment on loan of £14,000 and £300 to £400 paid for street lighting over and above the price charged for gas, and we get, says the writer, £1,800 or more for the electric light over and above the cost of lighting the town with gas.

Bromley. The Electric Lighting Committee of the Bromley Local Board have reported that at their meeting on Oct. 11 they considered the steps to be taken for giving effect to their electric lighting order, and they recommended that the clerk and the surveyor be instructed to draw up and issue a circular to householders to ascertain the number of householders willing to take electric lighting on circuit, as suggested by Prof. Kennedy, and the approximate number of lamps required. The clerk reported that the Highways Committee would recommend the Board to proceed with the negotiations for the purchase of a piece of land in the Station road, a portion of which would be available for the erection of an electric lighting station. A letter was read from the Local Government Board transmitting a copy of a letter from Mr. H. J. Lansbury, who stated that the period specified in the first schedule of the provisional order had now expired, and enquired whether an extension of time had been granted. As the order was not granted until July, 1891, the period specified did not expire until July, 1893, and the committee recommended that the clerk be instructed to reply in accordance with the facts.

Windsor. At the meeting of the Windsor Town Council last week a long discussion was held on the position of the electric light company. It was explained that the contractors, Messrs. J. E. H. Gordon and Co., were carrying on a certain portion of the work as a pioneer installation. Mr. Dyson proposed that as the Board of Trade had no power to grant an extension of time the Board be requested to revoke the provisional order. Mr. Drewe moved an amendment that the Council regret that the electric light company have not satisfied the Board of Trade that they are in a position to fully and efficiently discharge the duties and objects of the provisional order, but in order not to prejudice the action of the Council in future the town clerk give notice to the Windsor and Eton Electric Light Company, under section 14 of the order, that the Corporation disapprove of the company opening and breaking up any of the streets or highways or continuing any other works until they have satisfied the Board of Trade as required by section 7 of the provisional order. This amendment was carried, no one voting against it, the Mayor and other members having left the chamber. Mr. Soundy then moved that a committee of the non-interested members of the Council be appointed to confer with the electric lighting company and report to the Council. This was also carried.

South Staffordshire Trams. In a few days nine miles of the South Staffordshire electric trams will be at work on the overhead conductor system. The preparatory work is almost complete, and experimental runs have been made along the entire route. A large power station has been erected between Darlaston and Wednesbury, containing three large dynamos driven by three compound condensing engines of 150 i.h.p. The districts which will be worked by the electric cars are those between Wednesbury and Bloxwich, Darlaston and Walsall. The feed cable, which is of solid drawn copper wire, is about ⅜in. in thickness, No. 0 B.W.G. It is suspended from the projected bracket of a series of iron poles placed on the sidewalk of the roads against the kerbstones, and carried at a uniform height of 21ft. from the ground. Underneath it runs a trolley wheel which is projected at the end of an arm attached to the roof of the cars. In this way connection is established between the lines and the motors, which are placed out of sight beneath the floor of the car. The pressure of the current conveyed along the feed wire does not exceed 300 volts, which is the utmost the Board of Trade will allow in England. The cars are constructed upon the bogie principle and have only two wheels at either end. Both the motors are of 15 b.h.p. The return circuit is made through the rails and the earth to the generating station. The switches and brake levers on the cars are fixed under the steps at either end, and the driver stands in front in whichever direction the car may be traveling. Electricity is also employed as illuminant, and both inside and out the seats are constructed upon what is known as the garden principle, with reversible back rests. The construction of the line has been carried out under the superintendence of Mr. Alfred Dickenson, C.E.

Eastern Extension Company. The report of the Directors of the Eastern Extension Australasia and China Telegraph Company, Limited, for the half year ended June 30, 1892, states that the gross receipts, including Government subsidies, have amounted during that period to £246,988, against £254,878. The working expenses, including £26,430 for cost of repairs to cables and expenses of ships, absorb £79,282, against £71,177, leaving a balance of £167,706. From this is deducted £3,041 for income tax, £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving £132,771 as the net profit for the half year. Two quarterly interim dividends of 1¼ per cent. each, amounting to £62,500, have been paid for the half year, leaving £70,271 to be carried forward. An arrangement has been entered into with the Government of New Zealand for reducing the tariffs over the New Zealand cables from 3s. 6d. to 2s. per 10 words for inter-colonial telegrams and from 1s. to 3d. per word for international telegrams, the Government guaranteeing the Company against three-fourths risk of any loss that may arise from the reductions, and the Company bearing the remaining one-fourth. It has also been arranged for the Government of New Zealand to join in the Australian guarantee and receive the benefit of the reduced rates with Australia, but owing to the losses during the first year of the experimental tariff having been greater than was anticipated by the colonies, the guaranteeing Governments have requested the Company to increase the charges for ordinary telegrams by 9d. per word, making the rates between Europe and Australia as follows: 4s. 9d. per word for South and West Australia, 4s. 10d. per word for Victoria, 4s. 11d. per word for New South Wales, 5s. 2d. per word for New Zealand, 5s. 5d. per word for Tasmania, and 5s. 5d. per word for Queensland. The changes of tariff will probably take effect from December 1 next.

Bradford. The Bradford Town Council have agreed to sanction the application for a provisional order to expend £30,000 upon the extension of their electric lighting supply. At the Town Council meeting on Wednesday, Alderman F. Priestman, chairman of the Gas and Electricity Supply Committee, moved the adoption of the minutes of that committee. He said the minutes included a provision granting to the committee borrowing powers to the amount of £30,000 for the extension of works. The committee required something like £9,000 to complete part of the electricity works already sanctioned by the Council, the remaining money would probably be required for an extension in years to come. There was nothing of the sort coming up just at present. In fact, the committee had no intention of recommending extensions of merely prospective utility. The public were continually demanding increased supplies of electric light, and of course the committee would need capital if they were to cope with the growing demand. He hoped to see the day when the committee would have to come before the Council to ask for five times as much money as they now needed. He certainly hoped that the supply of electricity was going to be a distinctly progressive work. Some enquiry ensued as to the cost of lighting the town clock. This was stated to amount to £840 a year, at which Alderman Priestman expressed astonishment. The matter was one which really belonged to the Finance and General Purposes Committee, and no doubt the chairman of that committee had already considered as to what was the best course to take. There were many ways of reducing the cost of the illumination. Personally he was often puzzled to tell the real difference between the 8, 16 and 32 candle lamps. Perhaps the 32 candle lamps in use might, without inconvenience, be changed for 8 candle ones, or, on the other hand, the total number of lamps might be reduced. The minutes were approved.

Taunton. The Directors of the Taunton Electric Lighting Works, not being altogether satisfied with Mr. Kapp's report, Messrs. Laing, Wharton, and Down requested Dr. J. A. Fleming, of the University College, to report on their behalf. Generally speaking, it is more favourable than Mr. Kapp's, but the conclusions arrived at are much the same: the works and plant are equal to three times as much work as is now being done. If the output were increased to that extent the works might pay. The following is Dr. Fleming's summary: "1. That the system of electric lighting now in operation at Taunton is one which is, in my opinion, best adapted to the present requirements of the town. 2. That the plant is in very fair condition, and is of a thoroughly good type, and the general arrangements and site of the station have been made with all reasonable forethought for the future. 3. When the whole of the power available is being taken up, and some small additions made to it, there is no reason to doubt that it will be capable of producing the full output of which it is capable at a cost which will leave a margin sufficient to provide the necessary annual amount for the redemption fund for the first cost and for extensions necessary, if

it is taken over by the Corporation as it stands, at the figure which has been arrived at as its fair purchase value. 4. Taking it as it stands, and assuming that the necessary custom can be obtained (which is almost certain) to fully load up the existing plant, and provided that the minor improvements suggested, especially the use of a small alternator and the introduction of meters, are effected, I see no reason to think that the working of the plant daily from dusk to dawn will result in financial loss. On the other hand, the difference between the full gross possible revenue and total generating expenses should be sufficient to provide an annual contribution of £680 towards the redemption fund, and as the lighting extends should leave a margin of profit. 5. Having regard to the state of the plant, and its original total first cost—a statement of which I have been shown—and the fact that the proposed purchase price includes the freehold of the land, I do not consider that the proposed purchase price, which I understand is fixed at £9,300, is an unreasonable figure for the acquirement of a plant suitable for the supply of 1,500 16 c.p. incandescent lamps and 90 arcs. 6. If the arc and incandescent lighting is extended to the whole of the streets of the town, and if custom outside by private consumers can be obtained equal to a yearly demand of 100,000 units, I think that electric lighting might become a source of profit to the ratepayers."

Oxford.—Since the opening of the works of the Oxford Electric Lighting Company on June 18 last the progress of the business has been extremely favourable. Numerous applications for current have been received, and a large number of lamps are already connected with the mains. The public lighting of the streets in the centre of the city has been undertaken, and a number of the colleges, the theatres, hotels, and many places of business have been lighted. No electric supply company has started under more favourable auspices. The very perfect system of distribution has worked without a hitch, proving not only the admirable character of the machinery, but the great care with which the installation has been carried out. The chairman remarked on the occasion of the opening of the works that "the business of supplying electricity has passed its experimental stage, and has reached a development that there is little or no practical difficulty in furnishing a city with a supply of electrical energy which can be used for purposes of lighting, power, or traction, or even of cooking, of which you have seen illustrations presented to you this evening;" and, in fact, the economy of the system of supply promises to give a most favourable return to the shareholders of the company. The excellency of the machinery and the intelligence with which it has been worked has resulted, we understand, in an extraordinarily small consumption of coal for the output of electricity obtained. The Company's showroom has been supplied with a choice selection of fittings, especially adapted to the requirements of this city. The firms who have united in furnishing the Company's showroom are the following: Messrs. Benham and Froud, Limited; Laing, Wharton, and Down; Messrs. F. Osler and Co.; Strode and Co., Limited; and Frank Suter and Co.; besides cooking apparatus, motors, etc., by the General Electric Company, Limited. The applications for current received by the Company include the Corporation, for the lighting of High-street, Cornmarket-street, Queen-street, and St. Aldate's-street, with 16 Brockie-Pell arc lamps of 1,200 c.p. each, the price paid by the city being £27 per annum for each lamp burning all night, and £14 for half-night lamps; the contract is for three years. The theatre and principal hotels are lighted, and besides many of the tradesmen the following colleges take the light: Brasenose College, Hertford College, University College, Trinity College, Balliol College, Magdalen College, St. Mary's Hall. Since the commencement of the works the board of directors has been increased by the addition of Alderman Robert Buckell and L. A. Selby Bigge, Esq.; and Sir Henry C. Mance, C.I.E., has become chairman in the place of J. Irving Courtenay, Esq., who remains a member of the Board. The lamp-posts fixed at the top of St. Ebbe's and near the Martyrs' Memorial and other places were manufactured of wrought iron at Munich for the Company with the special object of suiting the architectural character of the city. The remainder have been manufactured by the Electric Construction Corporation, of Wolverhampton. In comparison with the lamp-posts erected in the City of London and other towns the design reflects credit upon the taste of the Company.

Dundee Station.—The *Dundee News* gives the following information relating to the work at the central station: "As it is expected that the central portion of Dundee will be illuminated by electricity before the New Year, some information relative to the construction of the works, as well as the position the city will occupy in reference to the illuminant as contrasted with other centres where it has been adopted, may prove of some general interest. The contracts for the works were accepted about the beginning of June, and work was begun at the central station in July. Satisfactory progress has all along been made—the main walls of the engine and boiler houses being now completed, and a commencement has been made with the roofs. The works consist of a one-storey range of offices facing Dudhope-crescent road, with a basement below for the storage batteries. Behind the offices are situated the engine and boiler houses. The engine house is 65ft. long and 25ft. 6in. wide, and it is handsomely decorated with enamelled brick, with a dado of coloured brick. There is also a freestone corbel for carrying the rails supporting the travelling crane. The engines, which have been contracted for, are six of the well-known Willans and Robinson type, and four of these are to indicate 135 h.p. each, and the remaining two will each indicate 60 h.p. The dynamos, which were provided by Messrs. Siemens and Co., London, are attached direct to the engine shafts, being fixed on the same bed plates, so that there is no belting or shafting of any kind. The boilers will be of the Lancashire type, and are being constructed by Messrs. Whyte and Cooper, Dundee. The same firm are also providing one of their air condensers, which will be placed on the roof of the boiler house. The arrangement is rather a feature of the Dundee electric works, and it should be mentioned that it is the only electric lighting station which has been fitted up with this class of condenser. Already the condensers have attracted the notice of electricians elsewhere, and enquiries have reached the station from time to time as to their mode of working. The switchboard, which will be placed in the engine-room, will be 24ft. long by 6ft. high. It is to be constructed on slabs of slate 1½in. thick, and on it will be placed the various instruments required for measuring and controlling the large currents which are to be dealt with. From the station the current will be carried by strips of bare copper supported in porcelain insulators in a concrete culvert to the distribution mains. Many of our readers have, no doubt, watched with interest the construction of these culverts during the six weeks that this work has been going on. These will extend from the lighting station to the Nethergate via Barrack-street and Tally-street, and to Murraygate by Meadowside-road, Panmure-street, and Commercial-street. Junctions will be formed between them and the distribution mains at the corner of Tally-street and Nethergate, at the top of Reform-street, and at the corner of Commercial-street and Murraygate. The distribution mains will consist, on the other hand, of cables insulated with vulcanised indiarubber and drawn into iron pipes. Considerable speculation has existed as to the manner in which the wires would be inserted into the pipes, having regard to the fact that the latter are laid before the wires. The method employed in getting the wires into their places can now be seen in operation. It consists of pushing a series of short bamboo rods connected by screws into the pipes in a manner very similar to that by which a chimney-sweep passes his brush up a chimney. Once the rods are through a rope is attached to the end, the rods are withdrawn, bringing the rope through the pipe, and these in turn serve to pull the cable through. An incident connected with the construction of the concrete culvert in Tally-street may be recorded. In the course of their operations the workmen dug up a considerable number of old bones, showing that the old parish churchyard must have extended over a considerable space beyond the present church grounds. Again, in Commercial-street the contractors in their excavations were greatly retarded, heavy blocks of stone—the remnants of old buildings—having to be cut through. Otherwise the work has proceeded without any special difficulty. The area within which the Gas Commission have at present parliamentary powers to supply electric energy is a small but compact one, comprising the centre of the city, so that the proportion between light supplied and lengths of street mains will probably be a very favourable one as compared with most other cities. Most of the London supply companies are charging from 7d. to 8d. per unit, although their output is a very much larger one than the Dundee works can ever hope to attain too. But against this it has to be remembered that their capital charges for the construction of street mains are immensely higher. It is expected that the cost for the Dundee works will not exceed £21,000, of which £7,500 is for the construction of street mains. In London, on the other hand, the cost of the mains vary from 50 to 75 per cent. of the total expenditure, so that Dundee occupies an advantageous position in this respect. The distribution mains being laid in iron pipes, it is, of course, impossible to make connections to these for the individual houses without breaking the pipes. Provision has, however, been made for this by leaving gaps in the pipes and constructing brick boxes there with covers in the pavement. At each of these points connections can thus be taken off to the adjacent houses. Where these boxes have not been provided the pipes will have to be cut to supply customers. As the work is being carried out by the Gas Commissioners, who have already a considerable clerical staff, it will not be necessary to provide a separate staff for the electric lighting works, and thus a further saving will be effected. This, of course, means a smaller capital expenditure, and it may therefore be hoped that the Commissioners may be able to make the works pay even at the low charge of 5d. per unit as fixed upon. The engine power at present provided for is sufficient for supplying 5,000 incandescent lamps, each of 16 c.p., and it must be gratifying to the Commissioners that already about 1,500 lights have either been contracted for or are in contemplation. Many of the large shops in the High-street and Nethergate have taken the light. The Eastern Club have negotiated for it, and it will no doubt be adopted in other large buildings. It is, indeed, anticipated that once the works are in full swing many who are at present holding back until they see the light introduced will become customers. The present system is the low-tension one, and therefore cannot be extended further than from 1,000 to 1,500 yards from the works. This would, however, include the whole of the residential district near the Barrack Park and the crescents behind the infirmary. No doubt the Commissioners will apply for the extension of their area in this direction provided they are warranted by a sufficient demand for the illuminant. The Commissioners are not precluded from supplying electricity to a much greater distance, as it will be remembered that in their original report the engineers proposed that the Perth-road district should be supplied by a high-tension current, which would be converted into a low-tension one at a sub-station before being delivered to consumers. This is a system which is now working very successfully in Oxford, where the whole of the current is produced at a station two miles out of the town, brought in on the high-tension system, and converted and distributed on the low-tension system. The question of the comparative

cost of electric light and gas light is a very important one to would-be consumers. Unluckily, it is a problem with so many indefinite qualities that it is almost impossible to state positively what should be the proper method of comparison. If both gas burners and electric lamps are assumed to be of the actual candle-power which they profess to be, and be placed in the same positions in a room or shop, and lighted for the same number of hours, the electric light at 5d. a unit would cost 1½ times as much as the gas jet supplied with Dundee gas at 3s. 9d. per 1,000 cubic feet. (In London the proportion on the same assumption is 2½d.) The above assumption, however, does not correspond to facts. The case is altogether different if we may believe Mr. W. H. Preece, F.R.S., electrician to the General Post Office, who, after a series of experiments on gas burners, ascertained that the ordinary house burner, from various causes, such as dirt, unequal pressure, etc., only gives 66 per cent. of its nominal candle-power. This is one element of uncertainty in the calculation. Electric light offers especial facilities for subdivision, and there is no objection to placing a lamp close to the surface it is required to illuminate, and thus a careful arrangement of the lights will often allow of a better illuminating effect being produced with a smaller total of candle-power. It therefore depends to a very great extent on the skill and experience of the engineer who fixes the position of the lamps whether the quarterly account for electric light will be higher or lower than the gas account used to be. Again, it is almost impossible to estimate beforehand what saving will be effected in the cost of cleaning and painting premises by the introduction of electric light. One example bearing on this point may be cited. Prior to the introduction of electric light into the Dundee Free Library the handsome wooden ceiling had to be cleaned and varnished every year, and yet it had still quite a dirty appearance six months after it was so dealt with. Quite a different state of matters has prevailed since the introduction of the new illuminant, the ceiling not having been cleaned for three years, and yet it looks quite fresh. While the lighting of Dundee has not been at any time a subject of complaint, it has frequently been remarked that many of our principal thoroughfares are not so well lighted as they might be. In the circumstances the step taken by the Police Commission yesterday to have the portion of the High-street in the vicinity of the Town House illuminated with electricity will be hailed with satisfaction. The Commission have entered into the arrangement as an experiment, but should it be successful the light will in all probability be adopted in several other of the principal streets. Before this time next year it may be hoped that all the main streets will be lit with arc lamps. The only other place in Scotland at present going in for electric energy is Glasgow, and it is to be hoped that Dundee will be the first to be lit up. One thing is certain, that much will depend on the success of the Dundee scheme in inducing other cities to have the illuminant introduced."

PROVISIONAL PATENTS, 1892.

OCTOBER 17.

18538. **A new construction of underground conduit for electric conductors.** Thomas Wallace, 65, Chancery-lane, London. (Complete specification.)

18542. **Improvements in certain brackets or supports for electric arc lamps, applicable also for supporting lamps of other kinds.** James Kershaw Grindrod, 18, St. Ann's-street, Manchester.

OCTOBER 18.

18602. **Improvements in electrical appliances for canes and analogous articles.** Stephen Douglas Smith and Oscar James Wells, 52, Chancery lane, London.

18661. **Improvements in electrical communication between lightships and other vessels, and for other purposes.** James Harold Barry, 26, Budge row, Cannon street, London.

OCTOBER 19.

18691. **Improvements in underground conductors for the distribution of electricity.** Sydney William Baynes, 37, Spring gardens, Manningham lane, Bradford.

18695. **Bannister's new and improved electric railway signal and point working system.** Charles Alfred Bannister, 40, Mornington road, Regent's Park, London.

18700. **Improvements in electrical ceiling roses.** Thomas George Poole and Woodhouse and Rawson United Limited, 88, Queen Victoria street, London.

18716. **Improvements in electric wire or cable conductors or conduits.** Alexander Kinnear Foote and Henry Richmond Potter, 70, Wellington street, Glasgow.

18732. **Improvements in the regulating devices of alternate-current arc lamps.** Joseph Sinclair Fairfax, 433, Strand. (Messrs. Schuckert and Co., Germany.) (Complete specification.)

18739. **Improvements in or relating to telescopic slides for electroliers, electric brackets, electric floor-lights, and the like.** George Frederick Sanders, 37, Chancery lane, London.

18763. **Improvements in and relating to electric apparatus for playing mechanical pianos, organs and other keyed musical instruments.** Alphonse Antoine Magnier, 45, Southampton buildings, Chancery lane, London.

OCTOBER 20.

18780. **An improved method of registering the value of an electrical current on one meter where the price per unit varies for different services.** George Harris Driver, 210, Euston-road, London.

18807. **Electrodes for secondary batteries.** Emile Andreoli, 16, Somerleyton road, Brixton, London.

18817. **Improvements relating to galvanic batteries.** John Alexander M'Mullen, 124, Chancery lane, London.

18844. **Improvements in dry cells or galvanic batteries.** Hugo Koller, 46, Lincoln's inn fields, London.

OCTOBER 21.

18847. **Improvements in alternating-current motors.** Henry Francis Joel, 44, Lavender grove, Dalston, London.

18866. **Improvements in and connected with the protection of electrical conductors and fittings.** Andrew [illegible] and Carrington Riddell Gordon Smythe, 5, Downes [illegible] rant, Kelvinside, Glasgow.

18868. **Improvements in unions for electric chandeliers.** Louis Ballet, 4, Corporation street, Manchester.

18878. **Improvements in the connections of the [illegible] of earthenware articles employed in connection with electrical switches, cut-outs, ceiling roses and the like.** Thomas Taylor and William Tunnicliffe, 8, [illegible] street, Birmingham.

OCTOBER 22.

18926. **Improvements in switch lampholders for electric lighting purposes.** Frank Geere Howard, 10, Berners street, London.

18965. **Process for the electrolytic decomposition of compounds of metals and sulphur.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Messrs. Siemens and Halske, Germany.)

18982. **Improvements in telephonic apparatus.** Edward Peake Davis, 55, Chancery lane, London.

18994. **Improvements in electromagnets.** Illius Augustus Timmis, 2, Great George street, Westminster, London.

NOTES.

Tesla.—Mr. Nikola Tesla is to deliver a lecture at the meeting of the National Electric Light Association at St. Louis.

House Lighting.—The title of Mr. Angelo Fahie's book is definitely announced as "House Lighting by Electricity."

Junior Engineering Society.—The presidential address by Dr. Hopkinson before this society takes place to-night (Friday) at eight, at the Westminster Palace Hotel.

Altona.—The State authorities of the city of Altona have granted a license to Herr Beringer, engineer, of Charlottenburg, to build an electric railway from Altona to Blankenese.

Plante Premium.—M. Gaston Planté left a legacy of 1,500 francs to be given as a prize to the person who makes an important advance in electrical science, and the French Académie des Sciences have accepted the responsibility.

Optical Telegraphs.—Experiments in optical telegraphy made in France on Mont-Valérien, with the aid of electrical apparatus, have demonstrated that it was possible to communicate with Rouen, a distance of 120 kilometres.

Institution.—The Institution of Electrical Engineers will open its session for the winter on November 10th at 25, Great George-street, Westminster, at 8 p.m., when a paper on "The Problems of Commercial Electrolysis," by Mr. James Swinburne, member, will be read.

Aluminium Electroplating.—The *Scientific American* for October 22 describes and illustrates some huge electroplating tanks erected at the Tacony Iron and Metal Company's works for electroplating with aluminium the great pillars and iron parts of the new City Hall of Philadelphia.

Smoking Concert.—The Electro-Harmonic smoking concert last Friday was a great success, Mr. Ganthony's amusing imitation of a phonograph being much appreciated. Mr. Gatehouse discoursed sweet music on the violin, and the part-songs and solos were received with rapturous applause.

Potential of the Atmosphere.—The readings of the instruments established by M. Mascart on the Eiffel tower serve to show that the increase in potential of the atmosphere with the height above the ground is a physical fact, and one likely to be of great utility in dealing with meteorological observations.

Mount Washington.—The carbons of the celebrated Mount Washington arc are those of Hardmuth, of Vienna; the positive one measuring 1½in., and the negative 1in. in diameter. The projector has a Mangin lens of nearly 15in. focus, and was made in Paris after a secret process by which the quicksilver of the reflector is not injured with the heat of the arc.

University Extension at Plymouth.—In continuation of the series of 12 lectures on "Electricity and Magnetism," Mr. H. L. Callendar, M.A., delivered an interesting lecture at Plymouth Technical Schools on Monday, on the chemical effects of the current. Striking experiments on electrolysis and electroplating were exhibited on the screen. There was a very gratifying attendance.

Village Lighting.—A small installation in the village of Liebenau, in Hesse, Germany, has just been completed by Messrs. O. von Miller and Co., of Cassel, for the mills of Baron von Pappenheim. The plant consists of a small dynamo, driven by the mill wheel, and 60 incandescent lamps. The latter are used for lighting the mills and also the principal street of the village, which, it is claimed, is the smallest in Germany that can boast of electric lighting.

A Methusaleh Lamp.—Mr. Ernest Kitson, of the Edison Company station at Bellefonte, Pennsylvania, has an Edison 107-volt 10-c.p. lamp, which he says was put in circuit April 1st, 1884, and has been in use constantly at an average of 13½ hours a day until May 30th, 1892, a total period of eight years and two months. This would give the lamp a total life of 40,000 hours—apparently the record up to the present. In addition, it is stated that during the last three years the voltage on the circuit has been 110 volts or over.

German Electric Tramways.—In the city of Gera an electric street tramway, designed and erected by the Allgemeine Company, of Berlin, on the overhead conductor or trolley-wire system, which was completed last spring, has seven miles of single track. Phœnix rails are employed for the surface permanent way, whilst for the overhead construction both metal girder and wooden poles have been erected to carry the conductor wires. The generating station serves not only to supply current for operating the tramway, but also for electric light and power purposes throughout the town.

Telephonic Communication at Flamborough Head.—The Trinity House, who are in charge of the lighthouses on the coast, have connected by telephone the lighthouse and fog-signal station. For some years two resident signalmen were located at the signal station, and a continual watch was kept for fogs by one or other of the men. The telephone has now been fixed so that in clear weather the signalman can retire, whilst the light keeper who is on watch has to observe when a fog arises, and then to communicate the fact to the fog-signal station without having to leave his post.

Electrical Standards.—A meeting of the Electrical Standards Committee was held at the Board of Trade on October 27. The committee discussed the report made to the British Association by the Electrical Standards Committee of the association in August last, and considered the supplementary report they propose to make to the Board of Trade. The following members were present: Sir Courtenay Boyle, K.C.B.; Major Cardew, R.E.; Mr. W. H. Preece, F.R.S.; Lord Kelvin, F.R.S; Lord Rayleigh, F.R.S.; Prof. G. Carey-Foster, F.R.S.; Mr. R. T. Glazebrook, F.R.S.; Dr. John Hopkinson, F.R.S.; and Prof. W. E. Ayrton, F.R.S.

Franklin Institute.—Papers were read before the Electrical Section of the Franklin Institute, Philadelphia, on the 25th ult., on "A New Ballistic Galvanometer, (*a*) With High Insulation and Graded Coils, and Constructed Closely to Theory; (*b*) With a New Method of Varying the Sensibility within the Widest Limits without the Use of a Control Magnet," by Elmer G. Willyoung. Also on "Some New Apparatus for the Most Exact Comparison and Adjustment of Resistance Standards and the Determination of Temperature Coefficients," by the same author; and "On the Measurement of Energy in the Three-Phase System," by Mr. Paul A. Winand.

Globular Lightning.—A curious instance of globular lightning is referred to in the *Meteorologische Zeitschrift* for September, 1892. On August 7, during a thunderstorm at Altenmarkt, near Furstenfeld, while the priest was administering the sacrament, the church was struck by lightning, followed by a loud explosion. A panic immediately ensued, and the congregation rushed out, notwithstanding the assurances of the priest that there was no danger. There was nothing to show how the lightning entered the church, but it is supposed it was by the conductor leading from the steeple. It is said to have been a

large globe, tapering towards the upper part, and after the explosion it left a strong sulphurous smell. The explosion was very loud and shook the building.

Accumulator Traction in New York.—The invasion of the accumulator into New York continues, and promises to grow serious. Nothing astonishes the American electrical engineer so much as the immense importance of secondary batteries in England except it be the backwardness of electric traction. We lately mentioned that a large order for accumulators had been received in England for a central station in New York. We now notice that accumulators for traction purposes are beginning to be used there also. The Waddell-Entz Company is to place on the Second-avenue line 10 cars of the regulation kind, 16ft. bodies, finished in highest style, equipped with Waddell Entz slow-speed single-reduction motors, driven by storage batteries of the same company. A power station, containing direct-driven dynamos and complete generating plant, will be erected at once.

Tea-Drying by Electricity.—The practice of electrical engineering is very different from other branches of engineering—for instance hydraulics and mechanics, inasmuch as, while the latter are fairly well defined in their scope, no one really knows what branch of business electricity will not next invade. And in this lies the great charm, and the great chance for young electrical engineers. At any time an entirely new field may open out lying quite outside ordinary practice. Of this we have a very good example in the business of tea-drying in Ceylon, now proposed, we see, to be carried out by means of electricity with a simple, clean, and economical process. Some gentlemen resident in Ceylon have brought the idea before certain influential electrical and mechanical engineers, we are told, in England, and the idea being favourably reported upon, may result in transforming the process.

Ring Lubricator.—A modified system of ring lubricators for dynamos has been brought out by M. Fabius Henrion, electrical engineer, of Nancy. The usual ring lubricators, now well known, consist of a ring of metal loosely hanging on the axle and dipping into a well of oil. This arrangement secures continuous lubrication, but at expense of oil, which is thrown off by centrifugal force, and also makes the box liable to become very greasy. M. Henrion's improvement, shown by drawings in the *Revue Industrielle* of October 22, has a well below the bearing partly filled with water, and on this floats some oil. The ring, which is pierced with round holes, rotates in a small chamber, passing through the bush of the axle. Some spider-leg wires lead off the oil drawn up by the ring. The ring itself is enclosed by an envelope, and the lubricator has been found to give great satisfaction.

Technical Instruction.—The Edinburgh School Board have taken a noteworthy initiative in introducing technical instruction in the shape of practical chemistry and manual training into the Sciennes Board School. Of the £700 voted by the Council, £350 has been applied in this school, under Mr. S. M. Murray, in fitting four rooms at the top of the building for technical instruction, and with the addition of these classrooms the school is now one of the best appointed in the kingdom. The apparatus includes the practical teaching of chemistry and electricity. Benches for 24 boys, and tables for physical experiments, are fitted up, and in the adjoining room, in a laboratory for 110 pupils, practical demonstrations are given. Other rooms are fitted for manual training in carpentry and wood-turning. A swimming-bath and a gymnasium is also fitted in the school, which now occupies a unique position in physical instruction.

Electro-chemical Decoration.—A process has been brought out by Messrs. F. Krantz and H. Zeissler for the decoration of metal objects by electro-chemical means. The metal object is first painted over with bitumen, and the design is reproduced directly by means of a photographic negative proof, or is made in the ordinary way on the bitumen coating and developed with turpentine. The object is then placed in an acid biting bath, composed of two parts of nitric and one of concentrated sulphuric acid, with three parts of water. When sufficiently bitten it is taken out, washed well to remove every trace of acid, and rapidly dried in a warm place. It is then placed in an electroplating bath composed of the following parts by weight: 12 of cream of tartar, 1 of carbonate of copper, 24 of water. The bath for other metals is obtained by replacing the copper salt by a salt of the required metal, for instance, chloride of silver or gold, or the ordinary electroplating solutions.

The Institution.—Our remarks upon the Institution's connection with the Press had hardly reached some of our readers before we received a communication from the secretary making a new proposal. We have, after consultation with some of our colleagues, decided not to accept the offer of the Council. It may, and possibly will, prove to be the case that we stand somewhat alone in our refusal. The reasons for declining are founded upon principle—with which some of our colleagues are in accord, though preferring to let matters take their chance, knowing that the proposal is one that will fail of its own inherent weakness. We have taken the liberty of doubting if the proposal really emanated from the Council, but is not rather the suggestion of an interested paper. Because we have refused to agree with the proposal, our readers need not, however, fear that they will be deprived of any account of what goes on at the Institution. The unauthorised programme is sometimes more effective in bringing about reform than the authorised, and at any rate permits more freedom of speech. No doubt we shall be ostracised in some quarters, but that penalty we can bear.

Physical Society, Glasgow University.—The programme of papers for the session 1892-3 is as follows:

Nov. 4.—President's Address.—James H. Gray, M.A., B.Sc.
Nov. 11.—Communications by members.
Nov. 25.—Paper on "The Attractions of Elliptic Cylinders." George A. Gibson, M.A., F.R.S.E.
Dec. 16.—Paper on "The Thermo-electric Power of Platinum and Mercury."—Angus M'Lean, B.Sc., C.E.
Dec. 23.—Paper on "The Viscosity of Air."—J. R. Erskine Murray, B.Sc.
Jan. 13.—Paper on "Time—Ancient and Modern Computations."—Magnus Maclean, M.A., F.R.S.E.
Jan. 27.—Paper on "Portative Electric Energy."—J. T. Niblett.
Feb. 10.—"Further Notes from the Board of Trade Laboratory." J. Rennie, M.I.E.E.
Feb. 24.—Lecture on "Some Illustrations of the Development of Mechanical Tissues in Plants."—Prof. Bower, M.A., D.Sc., F.R.S.
Mar. 10.—Paper on "The Liquefaction of Gases."—J. Brownlee, M.A.
Mar. 24.—Ninth Annual Meeting.
April 14.—Paper on "Capacity and Insulation Tests."—A. W. Meikle, M.A.
April 28.—Paper on "Electrical Engineering Laboratories." J. D. Cormack, B.Sc., C.E.

Leclanche-Barbier Cells.—The latest type of Leclanche-Barbier cells, now being introduced into England, are made in both wet and dry forms. The wet form has a positive element consisting of a hollow cylindrical agglomerate of carbon and peroxide of manganese, having a metal ring cast round the upper part fitted with a wooden stopper, through which passes the zinc rod. The zinc is h-

in position in the centre by a rubber ring. The two elements thus attached are placed in the ammoniacal solution in a glass jar having a rubber washer round the mouth. The weight of the elements pressing on this automatically seals the joint; the cell is, therefore, a closed one, and there is no evaporation of liquid to the complete suppression of creeping salts, which is so troublesome in the ordinary form of Leclanché cells. The construction gives greater efficiency, decrease in internal resistance by absence of rubber bands, etc., and greater facility for access. The Leclanché dry cells now also introduced possess all the advantages of the Leclanché and Leclanché-Barbier wet batteries. Their electrical output and durability are equal to those of the wet pattern having the same sized positive elements. They are essentially composed of a Leclanché-Barbier hollow cylindrical agglomerate cemented into an outer zinc case by a composition which, in itself, contains the ammoniacal solution. This composition hardens sufficiently to prevent any contact between the agglomerate cylinder and the zinc casing, but it always retains a certain degree of dampness. The orifice of the cylinder is closed by a wooden stopper to prevent undue evaporation from the interior. When the strength of the current falls its full energy can be restored by removing the wooden stopper and filling the cylinder with saturated ammoniacal solution, a portion of which is absorbed by the agglomerate and the cement. Among the advantages of this dry form of battery are the absence of all liquids, the fact that it is supplied ready for immediate use, and that it will work efficiently in any position, and occupies less space than the wet battery of equal power; but above all the great superiority over other dry cells that when its electrical force is diminished it can be immediately restored to its full power by resaturating it with ammoniacal solution, and this without interfering with its quality of "dry" battery.

Popular Electrics.—The Belfast commissioner still continues his interesting and careful descriptions of the various electric stations. A recent article was given to the description, with graphic details, of the West Brompton station of the House-to-House Company; and in this we notice a new simile to explain the production of electrical energy that we have not seen before—namely, that of the winepress. "The smallness of the staff required to work this station," says the commissioner, "is greatly due to the fact that all the electricity pressed out of the dynamo is all gathered together in one spot, at the switchroom." The dynamo is, however, more like unto a force pump—there we have the nearest analogy; and to produce, store, control, and distribute the energy is the object of the electrical engineer. The commissioner finishes his above-mentioned article by a little joke that, as the Brompton station is situate between a railway and a cemetery, it certainly is "between the quick and the dead." A well-deserved compliment is paid to Mr. A. H. Wood for his lighting of the Wild West Exhibition. The commissioner next describes Bradford central station, and has interviewed the energetic electrical engineer-in-chief, Mr. Baynes, who explained the beauties and advantages of the low-tension system as adapted in the most satisfactory manner by the North Country municipality. Mr. W. T. McGowen, the venerable town clerk, informed him of the Council's immediate intention to spend £3,570 on extensions to meet the increasing demand, and also that the Council have awarded a contract for the lighting of Kirkgate Market for £1,440. The number of customers for electric light has amounted to 200, requiring 20,000 8-c.p. lamps. The demand has also steadily increased for electricity as a motive power, motors even up to 20 h.p. having been installed. These are used for hoists, lathes, coffee grinders, roasters, and various other purposes; while electroplating—a trade hitherto unknown in the town—has been started. The account is very interesting and encouraging, and must give great satisfaction to those inhabitants of Belfast who, desiring to progress and to have the benefits of electric supply, were yet timorous as to the advisability of saddling the town with the expense. The example of Bradford, and we may add St. Pancras—both municipal stations, and both highly successful—will aid very greatly in enabling other corporations to make up their minds upon the subject; and Belfast may well be grateful to its enterprising paper in furnishing them with such complete information upon the subject.

Liverpool Overhead Railway.—One of the greatest electrical enterprises yet undertaken in this country is about to be opened, in the shape of the overhead electrical railway in Liverpool. Running along the line of docks in one of the most important shipping ports of the world, this line will serve a multitude of interests, and in itself will prove the forerunner of many similar undertakings. The total length of the railway, from the Herculaneum Dock at the south end to the Hornby Dock at the north end, will be 5¾ miles; and the whole of this, except the small portion north of the Alexandra Dock, will, it is expected, be opened next month. The trains will traverse this distance for five miles, all stoppages included, in 25 minutes, and there will be a five-minute service during the chief part of the day—probably from eight in the morning to five in the evening. Trains will commence running in the morning at five o'clock and cease at half-past nine, a 10 minutes' service being run from 5 a.m. to 8 a.m. and from 5 p.m. to 9.30 p.m. There will be 13 stations at first, others being opened as needed. It is expected that the fare will be a uniform one of 2d. for any distance. No collectors or tickets being needed, the passengers will simply pay at the turnstiles at any station and alight where they desire for the one fare. The first car was safely placed on the lines on Monday. Two of these cars will make up a train. Each weighs 14 tons, is 45ft. long, and has accommodation for 56 passengers—first and second-class. The cars will be practically the same as those on the Manhattan elevated railway at New York, except that they will have side doors instead of end doors with an outside platform. There will be a passage from end to end of the car, seats for two persons, each running the whole length on both sides. There will be a motor and a driver's box at each end, so that the train will run either way without the necessity of shunting. The current for the motor will be fed on the third-rail system, as with the South London line. The generating station, which is under the Lancashire and Yorkshire Railway at the Bramley Moor Dock, contains four horizontal side-by-side compound engines, each of 400 i.h.p., and each driving an Elwell-Parker dynamo, by which the necessary electric current is generated. The steam power is supplied from six 30ft. by 8ft. Lancashire boilers, working at a pressure of 120lb. to the square inch, a complete condensing plant being provided. On Wednesday the Water-street Station of the electric railway was visited by H.H. the Maharajah Gaekwar of Baroda and suite, who were accompanied by the Mayor of Liverpool (Mr. J. De Bels Adam), and were received on behalf of the Overhead Railway Company by Mr. F. Fox (for the engineers), and Mr. S. B. Cottrell (resident engineer and general manager). Trial trips of the cars, which are being made in Wolverhampton, will be run during the next few weeks, and it is hoped that everything will be ready for the opening of the line before the end of next month.

Battle Search-Lights.—There was evidently something of great interest to occur at Ealing last Saturday. Crowds had gathered round Captain Ronald Scott's house and grounds, where bands, horsemen, and a notable group of special war correspondents were assembled to take part in a battle by electric light. At 4.30 p.m. the 4th Middlesex West London Rifle Volunteers paraded in Ealing Broadway 350 strong, commanded by Colonel Somers Lewes. Arrangements had been made to have a sham battle on Horsenden-hill, and a company under Major Hopkins represented the enemy, the great object being to test the efficacy of the search-light projector in active field service. Captain Scott, who is an officer in the 4th Middlesex, had the management of the search-light in the hands of some of his assistants, and the experiments served to show that projectors need not be confined to stationary positions, but might be taken wherever artillery could be taken. The current was obtained from a set of accumulators, and a specially-designed carriage with broad tyres is to be used. On the eventful night, shortly before six, Major Riddell began the advance from Perivale Church. The difficult point was the bridge, and if the enemy could get past the day would be gained. The defenders, however, had all the latest resources of science at their command and the great search light flashing upon the ranks of the enemy revealed the brightly-illuminated forms of the grey-coated company. In actual war they would have been easy mark for fire. The light was flashed a little too soon for surety, and the enemy retired and took up a second line, but again were blinded by the glare of light from the projector, and stormed by rifle volleys. The defenders fell back and gave the attackers a chance to rush the bridge, when the light was turned on a mass of struggling human beings, and probably not half would have got over alive. However, the weight of numbers told, and when "cease fire" sounded the advantage was supposed to be in favour of the attack. But Captain Scott had proved beyond doubt the efficacy of his projector to the great delight of the numerous spectators and the satisfaction of the military men present. The battalion marched back to The Elms, Acton, where Captain Scott entertained his visitors. Experiments were then made with cloud writing by electric light. Words were projected upon the trees, buildings, and artificial clouds of steam. The face of Mr Gladstone was received with applause, and names of well-known advertisers were cast upon the clouds. Spectators could read clearly words thrown from the projector on the roof to distant belts of trees. The idea in these experiments is that, not alone for advertisement but for actual signalling in war, luminous letters and words might be satisfactorily employed. Captain Ronald Scott is to be congratulated upon the success of his initiative, and the great interest he has aroused in this use of the electric light. Captain Scott was ably assisted in his experiments by three of his works staff, Messrs. Tyson, Gibbons, and Edgelow.

The Lecturing Season.—When November fogs begin to fill the London skies, then is the time that the lecturer and the reader of scientific papers begins his serious work. The scope is widening. We have no longer alone the institution and the popular scientific papers, but we have the county council and the workshop lectures. No meagre field, these latter, for the budding aspirations of a coming man, and the audiences are inspiriting, which is not always the case with your real scientific audience, for those who attend are wishful of knowledge and bent upon using it. And there are reputations to be made in workshop lectures. Did not Dr. Fleming flesh his blade at Crompton's factory? His workshop lectures are still amongst the best he has done, and have proved an incentive to more than one good man. Other firms, from time to time, have followed this lead. It is now the time for directors, proprietors, and engineers-in-chief to consider the needs of their workmen and themselves. Many a worse move has been made than that of giving workshop lectures. Who knows, too, that besides the better knowledge of theory resultant therefrom, a budding Gramme, Kapp, or Ferranti may not come forth under the stimulus. We are yet not flush of good designers in the electrical world. Perhaps, after all, the greatly-felt need for lecturers who will lecture upon practical work is but an effect from the want of good text books. How clear and inspiriting a good lecture, how difficult to comprehend a book. The earnestest student must twist and turn his book, turn this way and that, and read over and over again for weeks before he masters his text-book. Did it not take Thackeray three months to read through a primer on chemistry? Possibly, nay probably, is this because no one has really discovered how to arrange a text-book in the truly logical fashion; a new kind of scientific text-book is badly needed, one based upon the idea that the reader need not, like the author, jump from here to there like a knight on a chessboard, but might read right through, and reading, understand. This "here and there" arrangement of facts and arguments is also, too often, the fault of the scientific paper. There are one or two offenders in this respect at our own institution. No one can tell for some minutes after the first break away of every paragraph, whither exactly the author is driving to; there is a curious crookedness about what in logic is termed the "dialectic" of their thoughts. Too often it is forgotten that the use of words by a speaker is simply to call up ideas, actual pictures, in a logical sequence in the mind of the hearer, and that the unity of scene of these ideas must be kept for the time being if the hearer is fully to understand. The greatest interest in a scientific subject will sometimes yield to listlessness and even petulancy if the writer of the paper have not mastered the elementary laws which regulate literary form. Science progresses, but it must go hand in hand with literature if its exponents are not merely to rest dumb artificers. In scientific theatre, hall, classroom, and workshop there is scope for advance, and the coming season should receive its advance in style as well as in scientific achievement.

Mansion Lighting in Scotland.—The following interesting account of a Perthshire mansion lighted by electricity is given in the *Dundee Advertiser*. "The base of Schiehallion, one would imagine, is not the likeliest place to look for the introduction of the newest appliances in connection with the electric light. Yet it is so. Mr. Bunten has just had the mansion-house on his beautiful estate of Dunalistair lit by electricity. Shortly after he became proprietor of the estate in May, 1891, he resolved to introduce the electric light. As Dunalistair is fully 10 miles from a railway station, and as the price of coal is necessarily high—between 30s. and 40s. a ton—the cost of driving the dynamo by steam power would have been very expensive. But Mr. Bunten soon saw that he had an efficient and a less expensive motive power ready to hand in the water which flows freely down the sides of Schiehallion, and he resolved to utilise it. The contents of three burns are discharged into a dam fully three-quarters of a mile from the mansion-house. The dam, which covers about a rood of ground, and is 14ft. deep, is fitted up with a filter bank to keep back the sand. From the dam the water is conveyed about 500 yards in 10in. iron pipes to the dynamo-house, which is situated on the banks of the Tummel, beside the woollen

bridge which connects Dunalistair and Crossmount. To accommodate the engineer and the necessary machinery, a model cottage has been erected. On the ground floor there is kitchen, scullery, and pantry on the one side, with dynamo-room on the other, while upstairs there are two bedrooms, pantry, bath, etc. In the dynamo-room, which measures 18ft. by 14ft., there are two turbines and two dynamos. The turbines are 12½ h.p. each, and arrangements are made so that one turbine and one machine can run, or the two together, if required. The dynamos are the Edison-Hopkinson patent, and were manufactured by Messrs. Mather and Platt. The current is led by two conductors from the dynamos to the mansion-house, a distance of between 400 and 500 yards, and there are branches from the house to the stables and laundry, about 200 yards beyond. The premises are fitted up on the distributing system with fully 300 lamps. With the exception of one Sunbeam lamp of 150 c.p. in the stable yard and 18 lamps of 5 c.p. each in the billiard-room, all the lamps are Edison-Swans of 16 c.p. each. In the roof of the dining-room a crystal bracket is fitted up with eight lamps, and by an arrangement of two switches either four or eight can be used as desired. Sockets have been fitted up throughout the room for portable lamps. In the library there is a crystal bracket with four lamps and a number of sockets. There are eight lamps in the front hall, six on the main staircase, five in the smoking-room, while in the billiard-room, besides the 18 lamps already mentioned, there are a number of side brackets. All the bedrooms are lit with adjustable crystal pendants, and besides there are sockets for portable lamps. The adjustable lights above the mirrors in the bedrooms are quite a new feature. Numerous lights have been fitted up in the passages and corridors. There are seventeen in the stable, five in the laundry, and eight in the dynamo-room and dwelling-house, beside one at the front door to light the bridge of the road. Messrs. Mavor and Coulson, Glasgow, fitted up the electric plant, while the turbines were supplied by Messrs. Silkes and Co., Kendal. The whole of the work was designed and carried out under the superintendence of Mr. Angus Murray, of the Anderson Foundry, Glasgow. Since the installation was effected everything has wrought most satisfactorily, and the light Mr. Bunten says he has found to make all the difference between comfort and discomfort in a country house in the dark wintry nights. The cost, including the price of the cottage, amounted to close on £3,000. By adopting water as a motive power the necessity for accumulators is entirely dispensed with, and an immense saving of money is effected. The capacity of the wires is sufficient to carry double the number of lights that have been fitted up.

Lithanode.—It is very interesting to watch the gradual development of a business from small attempts to greater and greater flights. A material is invented, like Mr. FitzGerald's lithanode, which has most if not all of the qualities which are required for an electric accumulator—solidity, lightness, great capacity; it is employed at first for a few portable batteries—we remember the little plates made in our presence a year or so ago, when we first drew the attention of electrical engineers practically to Mr. FitzGerald's inventions. Since then great strides have been made in the practical organisation of the business. Mr. J. T. Niblett, one of Lord Kelvin's old assistants, an exceedingly capable electrical engineer and organiser, has put his energies into the practical part of the business, and it is not too much to say that lithanode promises to become a standard article for electrical needs. We have the catalogue of the Lithanode and General Electric Company before us, which illustrates the present position of these batteries. Made from compressed protoxide of lead, with a chemical to make the spongy mass set solid, the lithanode can be formed of various qualities to give greater or less proportion of peroxide, the usual proportion being between 80 and 90 per cent. A non-oxidisable metal, platinum or gilded lead, is used for conductor, and with this arrangementan element is obtained practically free from local action, and one which will retain its charge for a long time, even when partly discharged and left in solution. The great advantages are large capacity for weight of material and solidity of plate, both advantages making lithanode particularly useful for portable batteries as cells for miners' lamps and for accumulator traction. Larger-sized cells are made of the Frankland-Lithanode type, blocks of lithanode being cast round with melted lead. Stock patterns of these are made with capacities ranging from 30 to 600 ampere-hours, capable of discharging at rates from 5 to 100 amperes, making batteries very suitable for private installation use. A special cell for station work is now being made, and will be capable of discharging at the rate of 1,000 amperes for a period of one hour without appreciable fall of potential. Where special lightness is required, the negative element is formed by compressing lithanode upon a double network of copper gauze, and an element is obtained of great strength and but half the weight of ordinary negative plate, giving a net gain of some 20 per cent. in the whole cell—no mean advantage for transport work. Great attention has been paid by the Lithanode Company to portable lamps, and a number of adaptations are to be seen at their showroom and works at 64, Millbank-street, Westminster. An extremely handy form of portable reading lamp, made in 2, 3, 4, and 5 cell sizes for runs of two to eight hours has a detachable lamp for use in the buttonhole for railway travelling; it can also be affixed to the battery in an upright or horizontal position, making a simple hand lamp or a lecturer's reading lamp, as desired. Fitted with non-actinic glass, it has been much appreciated by photographers for dark-room work. A smaller lamp with two cells in flat form will slip entire into an ordinary pocket; it has been much used by policemen, omnibus and tramcar conductors. A great future for these lithanode cells and lamps is for omnibus, car, and train lighting. Being small and solid, the cells can be easily and safely handled, and already many of the London omnibuses are so lighted by the Lithanode Company's cells with extremely satisfactory results. The lithanode cells have made themselves a special name in two important fields—namely, for miners' lamps and for theatre stage work. Miners' lamps are made in two sizes, weighing 4½lb. and 3½lb. respectively, steel-plate coated and strongly made. They have been well tested and have proved their usefulness. For stage work a number of specially light cells have been made for the fairies to wear on their backs, lighting a luminous star on the forehead. At the Crystal Palace pantomime these electric stars were used with very handsome effect. The Lithanode Company also make a small testing cell of zinc and lithanode a few inches high, with a potential of nearly 2½ volts each, which have been found extremely useful for making up testing sets. With 500 of these little cells an available pressure of over 1,000 volts is always at disposal for testing purposes, and the whole set goes into a moderate-sized cupboard. Such a set is illustrated in the catalogue. The company accept contracts on a maintenance basis, and as the merits of their wares are more widely known we may confidently expect continued increase of the usefulness of the lithanode.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC.MEM.INST. ELECTRICAL ENGINEERS.

IV.—GAS AND OIL ENGINES.

(Continued from page 433.)

Ignition Tube.—The gaseous mixture is fired in the modern gas engine by means of an ignition tube, and the following account will explain how it is done: The tube is a short piece of ordinary wrought-iron gas piping, ⅜in. to ½in. diameter and about 7½in. long, the top end of the tube being closed. The tube is placed over the flame of a Bunsen burner, and so made red hot, the lining of the chimney covering the tube, consisting of asbestos. The top of the chimney is closed by a perforated cover, so as to prevent any dust or foreign matter falling in; a tap regulates the amount of gas in the Bunsen burner, and in practice this tap must be adjusted so that the tube attains a cherry red heat, which can easily be seen by glancing down the chimney, and on no account must this degree of heat be altered. Any excess will quickly burn out the tube, which signifies stoppage of the engine. A caution must here be given not to look down the chimney more than necessary, and to do so quickly, since when a tube gives serious injury to the sight would result to anyone caught. Passage between the ignition tube and the interior of the cylinder is opened and shut by the movement of an ignition valve, this valve being operated by a lever, which is acted upon by a double cam on the screw shaft. When the piston is compressing the mixture, it is necessary that the communication between the cylinder and the ignition tube should be cut off, therefore the lever lifts the ignition valve, which enters an aperture, thus effectively closing the passage. To provide for any leakage of gas that may take place from the cylinder, a hole allows it to escape into the atmosphere. When the compression is finished, the cam allows the lever to drop, hence the valve drops on to its seat; the passage is now open, so that a quantity of the compressed gas from the cylinder rushes through into the hot tube, which ignites it at once; the burning gas being forced back re-enters the cylinder and ignites the compressed charge. Two chambers are for the purpose of receiving the burnt products of the gas which fires the charge, to avoid as much as possible any choking up of the passages by residuum, etc.

Life of Tubes.—The ordinary wrought-iron gas tube may be reckoned to last 30 hours, but this is not guaranteed, for some only last a few hours; on the other hand, some may last 60 hours. In running, it is advisable to change them every 24 hours of actual work. If the gas engine is not doing any particular work, when stopping would not signify much, such as charging accumulators in the daytime, etc., then the tube might be left in until it burnt out. Lately, Messrs. Crossley have put on the market a greatly improved tube; it is made of steel with some alloy, the exact composition of which is kept secret, and they will last twelve months. Concerning these tubes, the author has just been informed by Messrs. Crossley that one of their customers brought them a tube which had been in use from January to October, and was still in good condition after working 10 hours per day. The superiority and advantages of these prepared steel tubes over the wrought-iron tubes is thus evident. For it causes great inconvenience and annoyance when the electric light goes out suddenly through the failure of the ignition tube. The cost of these steel tubes is high, 12s. 6d. each, and 15s. with holder, whereas the iron ones are only 2½d. each; in addition, the steel tubes must be handled with great care, as they are extremely fragile, and the slightest knock would fracture them. But, as said before, where it is of great importance for the gas engine to run without danger of stopping, the high cost of the steel tubes is a trifle in comparison.

Steady Running, etc.—The latest and most improved form of Crossley's high-speed gas engine for electric lighting is fitted with their patent controlled tube ignition. These engines give a most remarkable steady drive, equal to a steam engine; this is owing to the two very heavy wheels on the engine, either of which can be used as a driving wheel; these wheels are also loaded with a mass of metal near their axis. Another reason for their steadiness is their high speed—250 revolutions per minute—so that two such heavy wheels rotating at this speed possess an enormous amount of momentum, and, therefore, the explosion of the charge does not tend to jerk the speed.

Governors.—A gas engine consumes gas exactly in proportion to the load, and this is effected by the aid of a governor. In the case of the above type, in the screw shaft, which works the valves, there is another cam, having three grooves cut in it—each groove promoting a different action. The governor as it rises and falls in response to the load actuates a lever which shifts to and fro, shifting a wheel into one of the grooves, and thus the revolving cam moves the lever to a greater or less extent. This movement of the lever works the admission valve, a strong spring attached to the lever tending to hold the lever down, and so keeps the valve closed when the cam is not acting. By this arrangement the amount of gas admitted into the cylinder is in proportion to the power developed.

In Tabulation 11, given below, the results of running costs, as calculated out for steam and gas engines, are collected together, so that the difference existing between the two can be seen at a glance. The large steam engine gives 40 b.h.p., and the large gas engine gives 35 b.h.p., these two sizes being sufficiently near for comparison; same with regard to the small engines, where the steam engine is 10 b.h.p. and the gas engine 9 b.h.p. The columns denoted by A give the price of 1 b.h.p. per annum, whilst the columns denoted by B give the price of 1 b.h.p. per hour in pence.

TABULATION 11.

Large Plant.

Hours per annum.	Steam A.	Steam B.	Gas A.	Gas B.
3,000	£10 0 0	·800 or [illegible]	£10 16 7	·86 [illegible]
1,500	7 10 0	1·200 or 1¼	6 4 1	1 [illegible]
750	6 5 0	2·0 or 2	3 17 10	1·24 [illegible]

Small Plant.

Hours per annum.	Steam A.	Steam B.	Gas A.	Gas B.
3,000	£19 11 0	1·56 or 1½	£16 12 8	1·31 [illegible]
1,500	16 8 6	2·60 or 3	10 8 10	1·6 [illegible]
750	14 7 3	4·75 or 4¾	7 6 10	2·[illegible]

Some interesting results are shown by this tabulation. It will be noticed that when running for 3,000 hours per annum the steam engine and gas engine are about on a level for cost, and that as the running hours are shortened so the cost of a gas engine becomes less than that of a steam engine. Coming to the smaller plant, we see that gas has a most decided advantage, even for long hours, and for short hours it is only half the cost of steam. We are thus led to the following conclusion:

With engines of about 40 b.h.p. running 3,000 hours, the cost for steam and gas are about equal;

As the power decreases, so gas will be less than steam.
As the power increases, so steam will be less than gas.
As the hours decrease, so gas will be less than steam.
As the hours increase, so steam will be less than gas.

Dowson and other Gas Producers.—A gas producer is an apparatus for manufacturing explosive gas or vapour. The fuel used may be divided into two classes: (1) coal, wood, etc.; (2) petroleum and other oils, fats, etc.

The best known gas producer used for generating gas for driving gas engines is Dowson's, the gas produced being named Dowson gas. This gas is made in the following way: Coal, or other suitable fuel, is burnt in a steam producer, the steam is mixed with air, and the mixture forced through an incandescent mass of burning fuel placed in the generator. The steam is decomposed into its constituent parts—namely, hydrogen and oxygen. The hydrogen passes

off, while the oxygen from the steam and from the air combines with the carbon to form carbonic acid gas (CO_2), this afterwards, mixing with more carbon, becomes reduced to carbon monoxide (CO), so that the gas produced consists of carbon monoxide, together with hydrogen, and small quantities of CO_2, nitrogen from the air being present in large quantities. Owing to the large quantity of carbon monoxide gas that is contained in Dowson gas, this gas must be used with great caution, since CO is a deadly poison, and an atmosphere containing, say, 2 per cent. of it would endanger life. The plant, however, is made very secure, and although used a great deal very few fatalities have occurred.

The heat of combustion of Dowson gas is one quarter of that given by an equal volume of coal gas, consequently four times as much is required to drive gas engines, so that where 20 cubic feet of coal gas is consumed per brake horse-power, more than 80 cubic feet of Dowson gas is required. The plant takes up very little room, and gas is manufactured at a very rapid rate. For example, a ground space of about 10ft. square would accommodate a plant sufficiently powerful to supply gas to a gas engine giving 45 b.h.p. Comparing this with the space a steam boiler takes, it is about on a par.

From tests which have been made, it is found that using coal to produce Dowson gas to drive a gas engine, only 1·3lb. of coal are consumed per brake horse-power per hour. This test was for an engine giving 7 b.h.p. A more recent test, where a Crossley Otto gas engine developing 170 i.h.p. was driven by Dowson gas, gave a consumption of coal of ·883lb. per indicated horse-power hour, and only 52lb. of water for everything—a most astonishing performance; this works out to ·08, or about $\frac{1}{12}$ of a penny per brake horse-power hour, using coal at 15s. per ton.

As an example of gas made from oils, fats, etc., we will take Mansfield's oil-gas apparatus. In this apparatus, the oil, or fatty matter, is vaporised in a retort heated by a fire of coal, wood, or other suitable fuel; the gas given off is passed through water to abstract all tar products, and is then purified by being passed over a mixture of slaked lime and sawdust. The kind of oils mostly used are those known as "intermediate," they have no unpleasant smell. It is found that 1,000 cubic feet of gas can be made from 10 gallons of oil, or one gallon will supply 100 cubic feet of gas. For large-sized gas engines the consumption of oil gas may be taken as about 10 cubic feet per brake horse-power per hour. Oil costs, say, 4½d. per gallon, and the cost of fuel in the furnace is about 1d. per 100 cubic feet of gas produced, and since one gallon will produce 100 cubic feet, hence total cost will be 5½d., or, say, 6d. per 100 cubic feet, allowing 10 cubic feet for 1 b.h.p., this comes to ·6, or ⅗ of a penny per brake horse-power per hour.

Petroleum Oil Engines.—Of late years petroleum oil has provided a most important and extensive source of fuel, and entirely supplies the place of coal in districts where that fuel is scarce and oil is plentiful, and every year this oil becomes more used. In South Russia, where the greatest petroleum wells in the world exist, the refuse of this oil is used in the place of coal in the furnace of the locomotives, the oil being stored in an oil-tank for the purpose, and is also used for steamers; 1lb. of petroleum oil will give out 50 per cent. more heat energy than 1lb. of coal, so that to give the same heat energy, oil fuel is 33 per cent. less in weight than coal fuel. In addition, it only occupies about one-half the bulk that coal does.

Another way of using petroleum for motive power is by vaporising it, and then exploding the oil gas, as in Mansfield oil-gas producers. But there is also a third way, and this is, perhaps, the most important, or at all events will become so, in every probability; this is by using the oil both as a fuel and motive force in the cylinder of the engine. This is illustrated by Priestman's petroleum oil engine.

The engine is very compact and entirely self-contained. The foundation of the engine contains a water-tank, supplying water to the cylinder jacket; this does away with a separate tank and piping. Underneath the engine, by the crank, is situated the oil-tank, the oil for a day's run being usually put in, while under the cylinder is placed the vaporiser; a side shaft works two pumps, the larger one being for compressing air, and the smaller one for circulating water round the cylinder. The working of the engine is as follows: the air pump forces air at a pressure of about 7lb. per square inch on top of the oil; a stream of oil is then forced along a pipe, and another stream of air along another pipe; both join and lead into the vaporiser, and then the air breaks the oil into a spray; whilst passing through the vaporiser the mixture of oil and air is heated by the exhaust gases from the cylinder. As the piston makes its forward stroke, it sucks in after it, by means of a suction valve, a quantity of oil spray and air. After compression this mixture is fired by an electric spark. The wires from an induction coil are led into the cylinder, the spark jumping across the gap between the two wires; the electric circuit is closed by the side shaft moving backwards and forwards, and so bridging across the two terminals, by means of a contact-piece. The burnt gases driven out by the exhaust port are utilised in heating the mixture passing through the vaporiser. The oil, when exploding, has the valuable property of lubricating the piston. Common petroleum oil is used, which can be obtained almost anywhere; this oil is particularly cheap in seaport towns, therefore oil engines should thrive in those places; an average price is 5½d. per gallon.

The amount of oil required to produce 1 b.h.p. per hour is proved to be less than 1¼ pints of oil; this will cost therefore ·86d., or ⅞d. One gallon of common petroleum oil, specific gravity ·800, weighs about 8lb. And since 1lb. of petroleum is equivalent to 1½lb. of coal in heat energy, therefore 1¼ pints of oil $= 1\frac{1}{4} \times 1\frac{1}{2} = 1·9$, or nearly 2lb. of coal; this is equal to $14,500 \times 2 = 29,000$ heat units to produce 1 b.h.p. per hour. So that the efficiency of the oil engine is about equal to the very best steam engine, as it utilises about 10 per cent. of the heat energy of the oil, and has half the efficiency of the gas engine using 22·5 cubic feet of gas per hour.

The way to start the Priestman oil engine is the following: First, the vaporiser must be heated by means of a hand oil lamp (a few minutes suffice for this) like heating the ignition tube of a gas engine. The air pump is then worked by hand by a lever for that purpose placed at the crank end of the engine (half-a-dozen strokes is sufficient for this), two or three turns of the flywheel, a couple of explosions, and the engine is off.

Common petroleum or lamp oil is perfectly safe to store and handle, since if a lighted match be dropped into a vessel full of this oil the oil will neither explode or burn, and the light will be quenched as if it had fallen into water.

The following tabulation gives the efficiency and cost of fuel per brake horse-power per hour for different motors:

TABULATION 12.

Motor.	Fuel.	Per B.H.P. per hour.	Heat units.	Efficiency.	Cost B.H.P. per hour.
Steam.	Coal.	4lb.	58,000	4·5%	·32 penny.
Gas.	Gas.	22·5 cub. ft.	15,000	17·2%	·75 ,,
Oil.	Oil.	1·25 pints.	27,550	9·3%	·86 ,,

Coal being at 15s. per ton, gas at 2s. 9d. per 1,000 cubic feet, and oil at 5½d. per gallon.

(To be continued.)

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE IV.

(Concluded from page 436.)

I will now speak a few words about the best arrangement of destructors which I have ever seen up to the present time, and that is one of the destructors which are used at Leeds. In 1878 the Corporation began, in an experimental way, with six cells at Burmantofts; in 1879, six more were put up at Armley-road; in 1882, four more cells at each of these places; in 1887, two more cells were put up at Armley-road, and in 1890 they built 10 new cells

* Cantor Lectures delivered before the Society of Arts.

at Kidacre-street. Thus, you see, Leeds has been steadily progressing. The first work was purely experimental, but they were thoroughly satisfied with the experiments, and they proceeded to continue the same work. At every step they have seen some improvement which could be introduced, and even at this present moment in connection with what I have just spoken of as the best destructor in existence, they are just going to put down a new destructor, and are totally going to introduce some new improvements. Here again they are going to have experimental work, and see how it does, and if it succeeds, as I think there is little doubt it will, they will proceed to build destructors on the improved plan. In these old destructors some steam was got up to drive a mortar-mill, the clinker being used to make the mortar of, and a considerable amount they have been able to sell. This clinker is always a source of trouble; one-fourth of the weight of the fuel is given back in that form. You cannot be burning iron pots and crockery without getting a certain amount of slag from it; nevertheless, it is found to be the cheapest way simply to put the whole stuff in as it comes from the ash pits, and burn everything, whether it is combustible or not, if I may use the expression. Consequently there is a large amount of slag, but this slag can be broken up and used for mortar, and it makes admirable mortar. It can also be used for road beds, road foundations, and ballasting, and when powdered and mixed with cement it can be made into artificial stones and paving slabs. The labour at each of these Leeds destructors is one foreman and engine driver, six furnace men, and one labourer. The whole place is perfectly clean, and kept in regular working order. Every pair of cells is charged every 25 minutes; they are banked at 1 p.m. on Saturday until midnight on Sunday. The damper to the boiler flue is closed at 7 p.m. on Saturdays. Everything is perfectly methodical. The fuel is carted in up an inclined road over a platform, and tipped upon the platform on the top of the destructor. In the diagram shown here of the Kidacre-street destructor, Fig. 2 (which I am able to give you through the kindness of the ...neer, Mr. Hewson, who has let me have the actual plans which were used in the construction), you will see that half the section shows the furnace, and the other half shows the cell flue, which is parallel to the furnace and intermediate between every two furnaces. You will recognise some resemblance to the Fryer destructor in this arrangement. The gases, however, before leaving the furnace, pass over the hottest part of the fire, and leave by a hole at the side of the furnace—marked cell flue in the left-hand section, and also shown in the right-hand section—thence passing along one of the cell flues into the champion flue, whence they pass on, it may be by the boilers, it may be by a by-pass to the chimney. This is the most important improvement that has been introduced by Mr. Hewson. Another great improvement on the old destructors is the addition of a forced draught. Instead of using a blowing engine, as they had plenty of steam from boilers which they did not want to use in any other way, to avoid having a steam engine to work, they have [illegible] the steam directly through a jet and through a funnel-shaped aperture (shown underneath the firebars), the jet of steam drawing air in through it, which passes through the firebars, and produces a fierce draught, thereby giving very much greater heat, and enabling us to burn a very much greater quantity of material in a given time. Five furnaces are on one side of the destructor, and there are five others behind these, and the cell flues in the middle between. The steam coming from the boilers is led to the funnel-shaped inlets for the air. The firebars are herring-bone shaped, and are capable of being rocked up and down by means of a handle, thus facilitating the disengagement of the clinker.

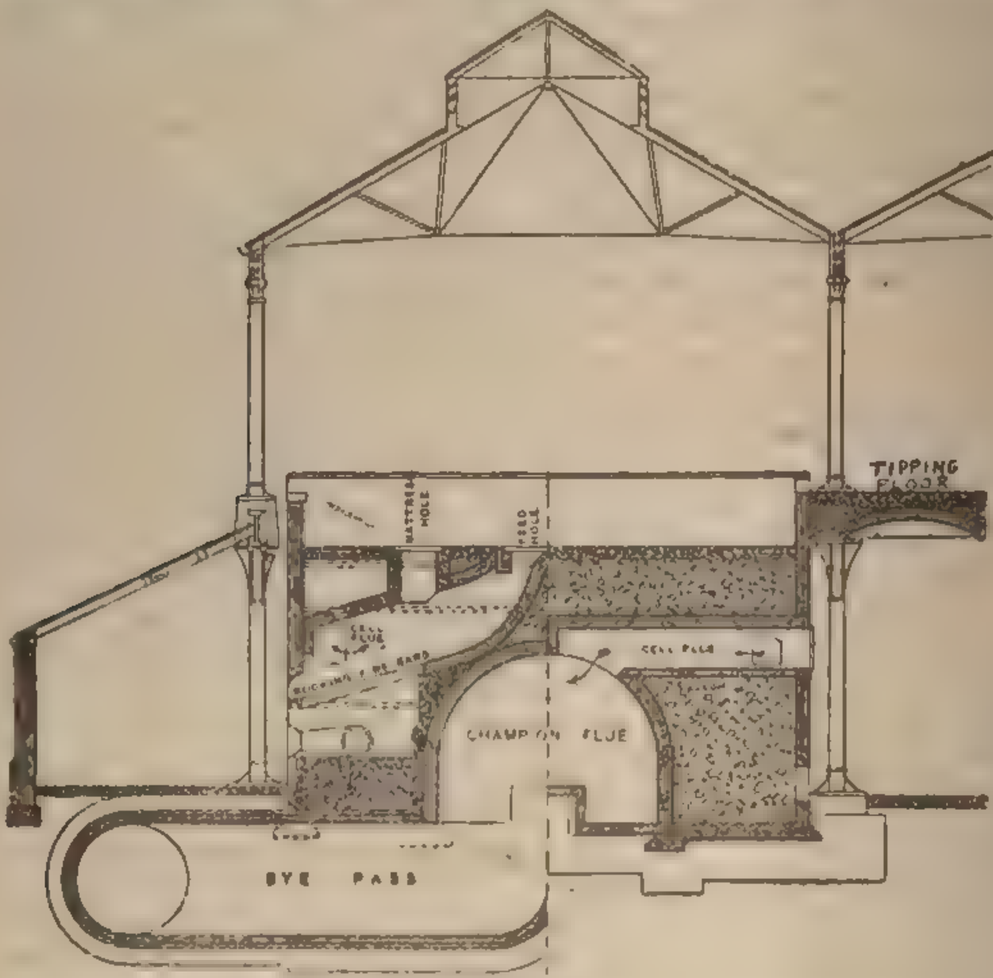

Fig. 2.

During a single year, up to 1886—that is, before the new destructor was built at Leeds—there were 20 cells, which burnt 35,248 tons of refuse. We may generally assume that each furnace is capable of burning about 34 tons a week. The refuse contains ordinary ashbin refuse along with trade and market refuse. Therefore, in addition to what I have mentioned as being found at Paddington, there was market refuse and other material of that sort, among which I may mention some totally different things

There were 11 cows burnt, 3 calves, 17 sheep, 4 goats, 298 pigs, 5 turkeys, 2 carcases of beef, 28 quarters of beef, 9cwt. of pork, 10cwt. of pickled tongues, 12cwt. herrings, 218cwt. shell fish, 1cwt. sugar, 285 dogs, 109 cats, 13 foxes, 1 sea serpent, 147 mattresses, beds, pillows, and bolsters, 7 blankets, quilts, and sheets, 36 pieces of carpet, 7 hearthrugs and mats, 33 pieces of clothing, 1 bedstead, 1 sofa, 1 chair, 1 bundle of rags. It is something to say that, without any complaint, the destructors at the high temperature at which they work were able to destroy all these objectionable things, which have been found so difficult to get rid of in any other way. The cost of working these furnaces for this one year before the new one were introduced was: For wages, £1,162; coal, oil, water, tallow, and gas, £181; implements and repairs, 227; rates, taxes, and insurance, £153; lime, for the mortar making, £78; total cost, £1,801; less mortar and old iron, which was sold, £395; leaving the total cost £1,406. Or, including interest, etc., a cost of 1s. 3d. a ton for destroying refuse. This is less than it would have cost to cart away the material and dump it, besides being, of course, far less objectionable, and the only healthy way of disposing of the refuse. The Leeds destructors which are going to be put up in the immediate future, have several improvements in the matter of more area; in the matter of washing smoke, to get rid of dust and other objectionable particles that go up the chimney; and the most startling and most efficient idea of automatic feeding. Mr. Hewson tells me that he has the intention of having the firebars formed in one continuous feeding belt, going along the whole range of the furnaces, the fuel being fed in at one end and carried along over one continuous furnace, being gradually burnt as it travels along. I am sure, judging by the success that Mr. Hewson has had in his past experiments with destructors, what he is going to do now will be very successful; and the smoke washing he has introduced is a plan which has proved to be the most successful mode of getting rid of smoke which has occurred to me.

Various tests have been made of destructors by pyrometers in Leeds. The temperature of the gases at the east end of the furnaces at Burmantofts was over 1,500deg. F.; at the west end, between the furnaces and the chimney stack, 1,150deg.; at the bottom of the chimney stack, 875deg., the furnaces being fed with air by an arrangement of steam jets, different to that in the new destructor, where they are considerably better arranged than has ever been the case before in the manner I have already described to you, the rapidity of burning being very much greater, and the temperature much higher. Dr Spottiswoode Cameron, medical officer to the Corporation, has given me valuable information in connection with the destructors. He has gone into these questions of the temperature and analyses of the gases, and he tells me that his experience is that the temperature measured with the pyrometer is very much a function of the observer, but they have had most careful men for measuring these temperatures, and in the new destructor the pyrometers do not read over 1,500deg. They are not capable of reading high enough temperatures to read the temperatures in this destructor, so that really during a great portion of the time the temperature is over 1,500deg. Mr. Alderman Ward has given some details of some tests which were made with the steam jets, and without the steam jets in this new destructor. The effect was, that while the steam jets were not in action the average temperature was 1,118deg., while the steam jets were in action the average measured was 1,464deg., but in a number of cases the temperature was higher than the 1,500deg. registered, because the pyrometer would not register more, so that you may be sure that the real average was over 1,500deg. Without the jets 6·2 tons were burnt in each cell per day; with the jets 6·7 tons per day. This is a marked improvement over the old experiments made in former times. Mr. Thomas Codrington, who made such an admirable report to the Local Government Board some years ago on furnaces, estimated the average temperature as follows for different places: In the Whitechapel district, 180deg. to 1,000deg., the average of eight cells being 490deg. At Ealing he found 855deg., 520deg., and 520deg. At Bradford, in the main flue, the temperature was 415deg. So that there is no doubt that in the Leeds destructor we have a much more valuable result, and it only remains to arrange for generating the steam in a proper manner to get a really good result. The residuary gases have been tested at Burmantofts, and the proportion in every 100 parts is: of air 81·67, carbonic acid 4·0, carbonic oxide 0·16, nitrogen 14·17.

Now, I could have given you a great many more facts about destructors which would have been very interesting, but I think I have said enough to show you that they will play a most enormous part in the industrial lighting of the future, and, at any rate, that the concluding subject of this course of lectures which I have delivered you is one of the most promising lines for engineers to study and develop as far as in them lies.

With regard to the other details of the lectures which I have drawn special attention to, I should just wish, in conclusion, to repeat to you one or two points to which I drew attention earlier. First, I wish to reiterate the fact that in large central station works on the alternating-current system, the plan which must recommend itself to engineers of the present day is to depart from the old plan, and to use low-tension secondary mains all over the district that is to be supplied; to have subsidiary stations with large transformers in them, with attendants to regulate them if necessary, or else automatic means of regulating them, so that we may have our machinery always at work at an efficient rate; and last, but by no means least, when we come to work in this way, and to put transformers into sub-stations, that probably the most efficient way will be to use alternations of much lower frequency than anything we have been dreaming of in the past; and for my own part I shall watch with interest to see what manufacturers will do when they see that this is the line on which work must be done. It will be interesting to see whether manufacturers will be ready to supply the machinery required for low frequency when that demand comes, as it undoubtedly must come in the immediate future. Low frequency is not only an advantage because large thick secondary mains can carry currents of low frequency efficiently, while they cannot carry currents of high frequency efficiently, but also because the currents of low frequency will be directly available for motors; and although I prefer to have motors on a separate circuit, there is no objection to using light motors, never going over 1 h.p. or so, on the lighting circuits; and for that purpose the low-frequency current will supply us with a solution of the problem immediately. We shall also be able to rectify the current, so as to use these slowly-alternating currents for charging storage batteries or to perform other electro-chemical operations. For all these purposes I have no hesitation in saying that that is the best means of modifying the existing practice in connection with alternate-current central station work.

With regard to continuous currents, and central station work at low pressures, all I have to say is that although I cannot see at the present moment that actual economy is introduced by the employment of accumulators in central stations, still they have an enormous convenience, and if they can be reduced in price they will be largely used for taking up part of the work at slack times, and also for taking up part of the work during the maximum output. At present, I cannot see that there is any economy in these two things. It is cheaper to generate your current direct, by means of a steam engine and dynamos, for these two purposes. But the value of accumulators is for regulating the pressure which you are to supply to your feeders; and so enormously important is it that something of that sort must always be used in central stations, that I have only to say that, in the operation, where you do not want to have a very large discharge of current for overcoming a breakdown in your machinery, if you are sufficiently satisfied with your machinery not to expect a breakdown, I would not use then the expensively made up accumulators. I would use nothing but simple plates of lead cut into a definite shape, without putting any oxide into them, or without any previous preparation of the lead, and without paying royalties for any patent rights. I would use the old Planté battery pure and simple, in the cheapest form in which it can be made.

I think these are the only points which I have mentioned in my lectures to which I wished to draw your particular attention, and I hope I may not find that I have made any mistake in drawing attention to these, as points which would deserve very great attention at the present moment

---

GEORGE WESTINGHOUSE, JUN., ON "NINETY MILES AN HOUR."

My attention has recently been called to an article relative to brakes and high-speed trains in which I was quoted as the authority. In consequence of the errors in the article referred to, and the importance of the questions raised, I desire, through your columns, to state some important facts bearing upon the subject, to which I am sure railroad officers will give careful consideration.

By referring to the celebrated Douglas Galton brake experiments it will be seen that, with the brakes in the best possible order, acting upon all of the wheels of one vehicle and up to their theoretical efficiency, it was only possible to reduce the speed at the rate of about 3½ miles per hour for each second the brakes were applied until the vehicle stopped; and it was further found, during these experiments, that the higher the speed the less the brake-shoes retarded the wheels with a given force applied to them; and that at 60 miles and upward the brake force to be thoroughly efficient would have to be at least double that now usually employed in daily practice at speeds below 50 miles. With trains of considerable length it was shown that with the brakes in the most perfect order possible, trains could be brought to stand from a speed of 60 miles an hour within about 1,200ft., the brakes in these cases acting upon about 95 per cent. of the weight borne by the wheels of the train.

With a *perfect brake*, acting upon all of the wheels of an express train running at 90 miles an hour, it will be seen from Table No. 1 that at the end of 10 seconds the train would still be moving at a little over 60 miles an hour, and would have travelled a distance of about 1,130ft. As a matter of fact, with the brake force now fitted to trains, the reduction of the speed of trains running above 60 miles an hour would, under favourable conditions, not exceed two miles for each second.

Table No. 2 will show the distance run during each second after the application of the brake, *under the best actual conditions*, and at the end of 16 seconds the train would be running 61 miles an hour, and would have travelled in that time 1,796ft.

It requires no more than to call attention to the fact that the human vision is limited to show the increased risk that is incurred running trains at 90 miles an hour, as compared with trains running at 60 miles an hour and under. A system of signals to provide for these high speeds would have to be absolutely perfect, and arranged at such distances apart that they would necessarily limit the capacity of the road for all trains that are run at a much lower speed, unless a double set of signals were provided, one for high speed and one for low speed.

The danger to a person crossing the tracks at a level with trains running at these high speeds would be multiplied many times, unless a system of gates were provided, with danger signals at nearly a mile from each crossing, which could only be lowered when the gates at the crossing had been properly closed; in fact, everything would have to be arranged so that nothing would be left entirely to the judgment of man.

It was the explanation of these points in a converation, concerning the running of running of trains at high speed by electricity, with a writer of a daily paper, who was interested in the subject, which probably formed the basis of the article to which my attention has been called. It may, therefore, not be out of place in this letter to state a few facts which will bear with force upon the question of substituting an electric locomotive for the present steam locomotive.

Electricity on Standard Railroads.—The modern passenger locomotive, for high speed trains, must be capable of developing at least 1,200 h.p., and it costs about 10,000dol.; that is, the engine, boiler, feed pumps, steam piping, and everything necessary to produce motion cost about 8dol. per horse-power. For the operation of a train by electricity, in place of one steam locomotive, there would be required the following principal items, costing, according to present prices of electrical apparatus, approximately the figures set opposite:

A stationary steam boiler, 1,600 h.p.	$16,000
A stationary engine, 1,600 h.p.	1[illegible]
An electric generator, 1,600 h.p.	2[illegible]
Motor for locomotive, 1,400 h.p.	32,000
	$81,000

In addition to the above there would have to be added the proportionate cost of the buildings and outside electrical construction for the transmission of the electricity from the generator to the locomotive.

There are innumerable places where electrical power will profitably supplant the steam engine, but I feel confident that the above figures, or any modification that may reasonably be expected, will be a most serious obstacle to the utilisation of electricity for moving standard railroad trains, even provided all of the mechanical details necessary for the transfer of electrical energy of 1,200 h.p. from a stationary to a moving object shall be satisfactorily worked out.

TABLE No. 1.

Speed	90	miles per hour
Feet per second	132	
Time lost applying brakes	1	second, with full application at end of second second
Reduction first second	0	miles.
" second second	1½	miles.
" each second after	3½	miles.

With the above condition, the following figures are almost accurate (fractions omitted):

Seconds.	Feet travelled.	Speed at end of
1st	132	90
2nd	131	[illegible]
3rd	126	[illegible]
4th	121 +	[illegible]
5th	116 +	[illegible]
6th	111 +	[illegible]
7th	106 +	[illegible]
8th	101 +	[illegible]
9th	96 +	[illegible]
10th	90 +	[illegible]

Total run 1,130ft. in 10 seconds

To obtain the above results upon dry rails and upon the level would require a brake force of at least three times the total weight of the train, and this should be properly distributed upon every wheel in the train, and there would be needed a device on each car to automatically reduce the brakeshoe pressure as the speed decreased.

TABLE No. 2.

Speed	90	miles per hour.
Feet per second	132	
Time lost applying brakes	1	second, with full application at end of second second
Reduction first second	0	miles.
" second second	1	miles.
" each second after	2	miles.

The best to be expected from present well-fitted trains, with brakes in perfect order, in speeds above 60 miles per hour.

Seconds.	Feet travelled.	Speed at end of
1st	132	90
2nd	131	89
3rd	129	87
4th	126	85
5th	123	83
6th	120	81
7th	117	79
8th	114	77
9th	111	[illegible]
10th	108	73
11th	105	71
12th	102	69
13th	99	67
14th	96	[illegible]
15th	93	63
16th	90	61

Total run 1,796ft. in 16 seconds.

—*Railroad Gazette*

PORTSMOUTH.

THE NEW ELECTRIC LIGHT STATION.

On Thursday last week the Mayor (Alderman T. Scott-Foster, J.P.) laid the foundation-stone of the new central lighting station, for the building of which Mr. T. W. Quick has the contract for £8,400. The contract was accepted on October 4, and the following day Mr. Quick commenced work on the foundations. The first thing to be done was to clear the site of the burnt *débris* which had laid there since the destruction of the music hall on Christmas Day, 1890. In getting out the foundations some difficulty was experienced, as the ground was honeycombed with cellars and excavations, but these were partly filled in, and eventually a level trench 10ft. deep was constructed. This to a depth of 7ft. was filled with a solid mass of Portland cement concrete, 4ft. wide, and then 3ft. of brickwork brought the foundations level with the surface of the ground. Upon this solid base the walls of the buildings will be raised, these extending from Gunwharf-road to St. Mary-street.

The station is in three sections. Adjoining the Board school in Gunwharf-road is the boiler- house, intended to receive five Lancashire boilers, the room measuring 56ft. by 50ft. The remainder of the frontage on this side is devoted to the coal-store, 31ft. by 56ft., above which rise the offices. A passage across the centre of the site is to be utilised for economisers in connection with the boilers, and behind them the engine-room will be constructed, a large apartment 100ft. long by 60ft. wide, with frontage into St. Mary-street. Between this and the engine-house the chimney shaft will rise to a height of 120ft., being of octagonal tapering form, with brickwork varying from 3ft. to 9in. in thickness. It is proposed to have a great concrete cube, measuring 20ft. each way, as a foundation, but it may possibly be found necessary to make the block deeper and even to adopt other methods to obtain perfect security should the excavations reach the bed of shifting sand forming the subsoil. The whole of the buildings will be of red brick, plain but not unhandsome, the plainness of the material being relieved by terra-cotta panels and mouldings. The offices, forming a storey over the coal-store, will cause that building to rise to a height of 50ft., the engine-house will measure but 2ft. less from the ground line to the apex of the roof, and the highest point of the engine-house will be 30ft. As an instance of the solidity of the building, it may be stated that the steps and staircases throughout will be of granite. The Corporation, we may add, have secured sufficient ground in Gunwharf-road to double the boiler accommodation, and the engine house is to be of such dimensions that the machinery can be duplicated without extending the building. Mr. Quick's contract is to be completed in six months, and it is being carried out with Mr. E. Price as clerk of works. The engineers associated with Prof. Garnett are Messrs. Waller and Manville, from whose plans the buildings are being erected.

The foundation-stone, which occupies a place in the wall facing Gunwharf-road, is a block of red granite, bearing the inscription: "This stone was laid by his Worship the Mayor of Portsmouth, Alderman T. Scott-Foster, J.P., October 27th, 1892." In a cavity below the stone were placed current coins of the realm, copies of local newspapers, and an illuminated document containing the following record: "This stone was laid by the Mayor of Portsmouth, Alderman T. Scott-Foster, J.P., in the presence of the following members of the Electric Lighting Committee: Alderman G. Ellis, chairman; Councillor R. W. Beale, vice-chairman; Aldermen J. Moody and A. Cudlipp, and Councillors G. Ashdowne, W. Avens, G. H. Dean, H. Kimber, H. Fuller, H. Croucher, R. Barnes, J. McAskie, W. T. Dittman, A. L. Emanuel, J. H. Corke, A. Ross, and W. L. Bamber; engineers, W. Garnett, J. E. Waller, and E. Manville; T. W. Quick, contractor; Alexander Hellard, town clerk; Philip Murch, borough engineer. October 27th, 1892."

ALDERMAN ELLIS said it was his privilege as chairman of the committee to ask the Mayor to lay the memorial-stone of the first electric lighting station built in the borough. His Worship, in his inaugural address at his election on the 9th of November last, expressed the belief that the electric light in the borough would become an accomplished fact during his term of office. Many delays had occurred, but they were not caused by the committee or by the engineers, but were entirely due to the inertia of the Local Government Board, and had it not been for the persuasive powers of Mr. Beale, their vice-chairman, probably the present Mayor would not have been able to perform that ceremony. The portion of land on which the buildings were to be erected comprised 1,850 superficial yards, and was quite adequate for all present purposes, but as electric lighting had spread most rapidly in other towns they hoped it would do so in Portsmouth, and they had obtained land on the other side should it be necessary to extend the buildings. He then proceeded to describe the building, remarking that the chimney-shaft would be a great feature in the work. It would be 120ft. high, panelled, and with cast-iron ornamental capping at the top. A second shaft of similar character would probably be built at some future time. Each of the five boilers would be 30ft. long and 7ft. 6in. in diameter, and to reduce the cost of labour—always an important item in electric lighting works—they proposed to have mechanical stokers and lifters, so that one man would have full command, and could coal all five boilers, which would give an indicated horse-power of 1,400. There would be two separate pipes from the boiler-house to the engine-room, so that in case of accident to either boiler there would be no possibility of a breakdown. In the engine-room two distinct types of engines would be provided, the object being to see what kind was best fitted to do the work, for they had to economise, as coal was exceedingly dear in this part of England. The first two engines would be a horizontal compound-condensing engine, with slow-speed alternators with rope driving gear; and Parsons turbo-generator, which made 5,000 revolutions per minute. The indicated horse-power was something over 1,000. The reason that that site was chosen was that they would require a large amount of water for condensing in these engines, and a salt-water pipe 1,000ft. in length and 14in. in diameter would be laid, the waste water being discharged into the Camber. Special care would be taken in fitting the switch-room, and in the test-room would be instruments of the best description, not only for testing the meters, but for seeing that every main in each street was in safe and proper condition every day. He believed that when the scheme was carried out Portsmouth would be the best lighted town in the kingdom, barring London. The street lamp-posts would carry 124 arc lights, each giving 2,000 c.p., and on each column there would be two brackets, each bearing an incandescent lamp, which would be lighted when the large lamps were extinguished at 12 o'clock. In asking the Mayor to lay the stone, he remarked that no man in Portsmouth could have done more than he had to bring this scheme to a successful issue.

A silver trowel, suitably inscribed, having been presented to his Worship by the contractor, the Mayor laid the stone, and after declaring it to be well and truly laid, said that in erecting that building they were rearing another monument of the progressive policy which the Portsmouth Corporation had been carrying on for the last 25 years. They had done what but few corporations had yet done—taken the initiative in the matter of electric lighting—and he saw no reason why they should not make it a success. He further ventured to prophesy that when the inhabitants saw the light the demand for it would be such that they would have to increase the supply. A dinner in commemoration of the ceremony was afterwards held in the Town Hall.

Ilford.—At the meeting of the Ilford Local Board, Mr. Jameson, president of the Ilford Ratepayers' Association, forwarded a resolution passed by that body inviting the Board to take steps to introduce the electric light into Ilford, and asking that the Board would receive a deputation upon the subject. The Chairman said he did not think they could very well refuse to receive a deputation, but what might come of it was a different matter. The Board would not take upon themselves to make private individuals a handsome present out of the ratepayers' money, and he believed the idea emanated from a servant of the company which supplied Chelmsford. It was agreed that the deputation be received at the next meeting of the Board.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free. Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. IX. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE STUFFY UNDERGROUND.

Unless the present writer is greatly mistaken, there is a hackneyed quotation from the classics to the effect, when translated, that "man is at once the cleverest and most stupid of animals." If classic authors never originated such a thought, they have been greatly over-rated; for most folks discover the truth of the assertion as soon as they cut their eye-teeth. Those who had money subscribed it of yore for the purpose of making large holes through the ground, so that quick transit might be obtained from one part to another without impeding surface life. So far, so good: these men were clever, but they proved very stupid, and as dense as the smoke and fumes in the aforesaid holes, when they did not—and their descendants do not—insist upon keeping the air within these holes, at any rate, as fresh as the air outside in the world above. Possibly the reason why greater care, for instance, has not been taken to ensure good ventilation upon the Metropolitan and District Railways may be that the directors of these lines consider the air so indifferent (and in November so thick) that the passengers down below are just as well without it. Those who prefer sulphur and steam to sulphur and air will not appreciate this joke; they will consider such a reason to be eminently practical, and will continue to enjoy the pleasures of the "steam sewer" as they now exist. But, fortunately, these good folks are in a big minority; most passengers are only too anxious to see improved methods brought into use, and it is for their benefit that the following details are given, in order to show what has been done elsewhere to remedy bad ventilation.

Taking up, therefore, the question of underground steam railways, the subject of perfectly ventilating these becomes one of cost entirely. The engineering difficulties—in spite of such formidable phrases as "churning the air," "increased tractive energy required," etc.—are not more than any well-trained expert would overcome at once. The question turns solely upon the willingness of directors—that is, the shareholders—to make a certain expenditure in order to improve the line, and therefore influence the traffic. On the London underground lines there seems a complete unwillingness to incur any amount whatever of expenditure in order to better ventilate the tunnels and so render transit more endurable to passengers. Baltimore—or rather the Pennsylvania railroad—has other views, and it is just now engaged in erecting a very complete installation for ventilating by means of electric energy the Baltimore and Potomac tunnel. The conditions existing upon this length of line are apparently just such as obtain, say, between Gower-street and Portland-road in the Metropolis, but the results in the two cases will be found to diverge somewhat widely. The Baltimore tunnel is built for two tracks, is semi-circular in shape, of a radius equal to 13ft. 6in., and giving a space of 22ft. from rail level to top of arch. Its length is 3,600ft. between portals, or just over two-thirds of a mile. About half-way a large and ornamental square ventilating stack has been built

to a height of 100ft. from the ground level, resembling in style and formation a Venetian campanile. From the base of this shaft is driven a short connecting tunnel about 20ft. long, in order to draw out the foul gases from the railway tunnel. At the base of the stack is fitted a circular horizontal fan, 15ft. 6in. diameter, which is driven by a half-twist belt from a countershaft. A 45-h.p. Thomson-Houston electric motor actuates the countershaft by means of belting, and the power to drive the motor is obtained from plant near the mouth of the tunnel, specially put down for the purpose. From the details given more or less officially with respect to this installation, it appears that the capacity of the fan—at a peripheral speed of 658ft. per minute—is sufficient to change the air of the whole tunnel in five minutes, supposing the velocity of the air to be about 42ft. per second, a quite reasonable amount. The energy required to actuate the fan may be calculated out from this as equivalent to some 20 h.p. There is apparently, therefore, a good margin for losses by friction, train resistance, etc.

Now here is the case of a steam railway tunnel of considerable length running under city streets, and accordingly well patronised by passengers. The directors of the line evidently think well enough of this traffic to consider its wishes, and, if possible, carry them out. Not only do they instal special plant for ventilating the tunnel in perhaps the best way possible, but in order to avoid the nuisance of having a steam engine and boiler in the centre of the city for the purpose of actuating the ventilation apparatus, they go so far as to erect the prime motor outside the more populous districts, and make use of the most flexible and economical power conveyor that they can find in the shape of electric energy for working the fan. The London steam undergrounds do not need altogether to go quite so far as this. The electric current is at their door—right along the line, and nothing would be easier than to build an underground chamber, with connection to the railway tunnel, for each of the worst lengths of these lines. An ornamental chimney shaft and a ventilating fan, worked by an electric motor supplied with current from the street mains, represent the sum total of what else is required. Most people possessed of common sense to a reasonable degree will say that, if these means were adopted to secure better ventilation upon the underground railways, they would feel inclined to sell their omnibus shares. Meanwhile they don't.

There seems no immediate prospect, unfortunately, of electric traction being employed upon these lines to replace the use of steam locomotives, otherwise the bottom would be knocked out of the arguments in this article, and its destination the waste-paper basket. Assuming it, however, to be saved from such a fate, and rewritten only, then it might be proved that even on electric undergrounds the need for efficient ventilation still exists. The great advantage would be that energy for working the fans could be obtained from the electric mains by which the traffic is operated. This is not (but ought to be) done on the City and South London Electric Railway; but that's another story.

PHYSICAL SOCIETY, GLASGOW.

The tendency of the times is seen by examining the programmes of the various societies and institutions connected with physical science. Of late years the old and present students in the physical department at Glasgow have formed themselves into a society, which keeps them in touch with one another and with the various developments that progression in matters scientific causes in the scientific world. We have from time to time given papers read and discussed before this society, and this year purpose to do so more systematically. Indeed, as all the members of the society know, an arrangement was long since come to by which this paper becomes the recognised organ of the society. Hence, there is no breach of confidence in giving some idea of the work of the forthcoming session. The presidential address will be delivered this evening by the president, Mr. James H. Gray, M.A., B.Sc., the subject being the "Electromagnetic Theory of Light." The author has performed a much-needed service in putting briefly and lucidly in this address the theory of Maxwell, and the various investigations that have since Maxwell's time been carried out, and are corroborative of that great man's views. Reference is made to the work of Poynting, in his now famous papers on "The Transfer of Energy in the Magnetic Field," and "The Connection between Current and Electric and Magnetic Inductions in the Surrounding Field"; also to the investigations of Lord Kelvin, Helmholtz, Hertz, Lodge, Prof. J. J. Thomson, Profs. Ayrton and Perry, and others, all of which tend to show the close connection between the propagation of light and of electricity. But the full text of the address will appear in our next issue. Meanwhile, of the other ten papers to be discussed during the session six of them are electrical, as will be seen from the programme given elsewhere.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BARE COPPER MAINS.

SIR,—A good deal has recently been written on the heavy leakages and other troubles due to electrolysis which have taken place in the underground mains system employed by several of the Paris companies. This has been attributed to the extensive use of bare copper conductors supported on insulators. We take this opportunity of pointing out that such troubles have not occurred in England, although the use of bare copper conductors has been very extensively adopted in London and in other towns. As we were the pioneers in the matter, we wish to explain the points wherein our successful English practice differs so very completely from the unsatisfactory practice that has been adopted in Paris.

Seven years ago, when we were responsible for the design as well as for the contract for the works of the Kensington and Knightsbridge Company, we proposed to the directors the use of bare copper conductors, and accepted all the heavy risk and money responsibilities which such a novel system of underground conductors would have entailed if it had turned out to be a failure. Now that its success has been proved, we consider we are entitled to whatever credit and saving has attended the system.

In working out our system of bare copper underground mains, we at an early date saw the absolute necessity of so

arranging the insulating supports that everyone of them could be instantly accessible for the purpose of being cleaned or replaced. We therefore devised means of putting our conductors under considerable strain so that the number of insulating supports could be reduced to about 120 per mile—that is, about 14 yards apart, instead of being spaced about two yards apart, as is necessary if the bare conductors are supported on mere notches in earthenware or other insulating bridges. Those who have examined our system in the West end of London, and elsewhere, will have noticed at intervals of about 14 yards the covers of the openings at which access can be given to every insulator. We use separate cylindrical insulators of the lipped or telegraph form, one for each conductor, which gives great insulating surface, and prevents the accumulation of moisture, and as a result we can guarantee a degree of insulation that is quite impossible when a large number of mere notched insulators are used, even when the latter are quite new. Our system, commenced seven years ago, has yielded unexpectedly satisfactory results. The means that we have adopted to prevent the access of water and gas have been perfectly successful, the insulation resistance of the whole system has been far higher than has ever been the case where continuously insulated cables were used, for reasons which will be readily understood by those practically acquainted with the maintenance of an underground network connected direct to the houses. All practical engineers in charge of such systems know that 90 per cent. of such leakage as exists on a supply company's system occurs either at the junction of the house service lines to the company's mains, or on the service lines themselves, just within the consumer's premises. As in our bare copper system, these junctions are made in the street boxes, and can be instantly examined or detached for testing purposes. It is found in practice that the localisation of leakages is greatly simplified, and hence the leakage itself greatly reduced.

If we are right in insisting that the culverts should be made impermeable to water and gas, and that the insulators should be arranged so as to give great insulating surface, and be completely accessible for cleansing and repairing purposes, it will be seen that the troubles in Paris can be readily accounted for. The Paris engineers came over to see our system during its early stages and copied it in some respects, but in others fell into the very errors that we had already avoided. They still continue to use a great number of insulators placed close together, these insulators being of a poor insulating quality, and the great majority of them being completely inaccessible. They take no pains to make their culverts impermeable to water and gas, and no arrangements have been made to enable them to inspect or clean their system. We think that the unsatisfactory results in Paris should be a warning to some English engineers who appear to think that the good results we have obtained can be equally well obtained by the use of mere notched insulators placed close together, but we very much fear that the great reduction of surface and difficulty in keeping these surfaces clean will cause a repetition of the Paris troubles. The fact, however, has now been proved beyond doubt that a well designed bare copper underground system is superior to any existing system yet tried for a low pressure distribution network. Such a system costs less for maintenance, testing, cleaning, and coupling up to than any other system with which we are acquainted.—Yours, etc., Crompton and Co., Limited,

R. E. Crompton, Managing Director.

Mansion House buildings, London, E.C.,
November 1st, 1892.

GAS-ENGINE ECONOMY.

Sir,—Doubtless, many on reading Mr Guy's excellent article on gas engines must have been struck with the great variation of efficiency between engines of large and small power. Of course, had it been a case of working a large engine at a small power, one could fully understand the loss of efficiency exemplified by the extreme figures given under Tabulation 10, but I fear Mr. Guy must have experimented on some very ancient form of 3 h.p. engine, or used some very poor gas to require 37 cubic feet per brake horse power. A reference to the gas engine trials made by Prof. Kennedy, at the instance of the Society of Arts, show that in a 6 h.p. (nominal) Atkinson engine the consumption per brake horse power at full load worked out 22·60 feet, including gas for ignition jet, and we find a Crossley 9 h.p. (nominal) working at 24·1 cubic feet per brake horse power. Any of your readers will, on application to the host of gas-engine manufacturers, be furnished with tests of their various machines, showing in all cases a much more limited and more economical range of consumption than that laid down by Mr. Guy.

I would also find fault with the amount put down for "depreciation," considering the allowance for repairs (3 per cent.). I do not think any user of a decent gas engine would find a necessity for providing 7½ per cent. for depreciation, in modern engines a new cylinder lining and an occasional setting up of the piston will keep your engine in first class condition for, in one case to my knowledge, 20 years (i.e., 10 years working night and day). Now let us see what we get with my figures.

SMALL GAS ENGINE.

					Per B.H.P.
A.—Invariable cost.					
Interest on outlay at 4 per cent.	£0	14	3	=	[illegible]
Depreciation on outlay at 5 per cent. ..	0	17	10	=	[illegible]
Repairs on outlay at 3 per cent.	0	10	8	=	[illegible]
Attendance..............................	1	13	4	=	[illegible]
	3	16	1		[illegible]
B.—Variable cost.					
24 cubic feet (might be 23) for 3,000 hours, gas being 2s. 9d.	9	18	0	=	79
Oil, waste, and sundries........	1	5	0	=	10
	11	3	0	=	89

Per B.H.P. B.H.P. per hour
So total annual cost = £14 19 1 = 1·113

Whilst making these remarks I would express my appreciation of the clearness and thoroughness of the [illegible] the articles, which are highly interesting.—Yours, etc.,

[illegible]

REVIEWS.

Electricity: Its Theory, Sources, and Applications. By J. T. Sprague. Third edition, thoroughly revised and extended. E. and F. N. Spon, London.

We remember the first edition of this book coming into our hands for review—not to review for a weekly electrical paper, because there was not one in existence. The world jogged on and the writer became connected with the first of the modern electrical papers, and the second edition of Mr. Sprague's book came into his hands for review. The third edition comes whilst connected with this paper, hence our opinion has been delivered before two constituencies, and now before a third. It is well within our recollection, without turning to the review, that in our first effort we were almost as fully in accord with Mr. Sprague as now. He has progressed in some directions, while in others he has remained more or less stationary. It will be unnecessary then at any great length to discuss Mr. Sprague's views, his work having been for many years before the public. When first published it inaugurated a new departure—it smote the scholastic opinions hip and thigh; indeed, although the latter have gradually accepted many of the opinions originally propounded or developed by Mr. Sprague, they have not accepted all, as a recent controversy with Prof. S. Thompson will prove. In this controversy, however, there was a lack of finality, both parties holding to the view that their opponent was beaten out of court. Mr. Sprague has always been a thinker, not a follower. He differs from modern physicists upon a fundamental point, and this means he differs with them entirely. Modern physicists explain all phenomena connected with light and electricity by means of an hypothesis involving the "ether." Mr. Sprague objects to this, and refuses to bow down to the Baal that requires an admission of all and sundry proper-

ties to an unknown "ether" in order to explain certain phenomena by its aid.

"A wise humility," he says, "will recognise its ignorance and a wise patience await fuller knowledge, rather than invent an artificial knowledge, which can only serve to disguise people's real ignorance from themselves, and to make them contented with it."

There is no humility among modern electricians: they formulate laws which are no laws, formulæ which require constants, and altogether a knowledge asserting, without admitting of contradiction, that what is is right—that is, so long as one of their sacred number does not suggest something different, when all follow the bell-wether. We fear that, although many of the heresies which appeared in the first edition have become orthodox, there still remain enough to keep Mr. Sprague outside the sacred circle and among the heretics. In fact, this one on the "ether" is enough, or we might refer to his preference to the old chemical notation rather than the new as a point of difference.

One or two more general references. We wonder somewhat that Mr. Sprague spared space to refer to the one and two fluid theories. For all practical purposes they are as dead as the proverbial doornail. Our wonder may not be so great when he tilts at those who, like ourselves, see more advantage in fostering the idea of the magnetic circuit and its phenomena by symbolism similar to that which serves for Ohm's law; yet it is evident that he does not here feel quite sure of his position. An elaborate paper, recently published in America by C. P. Steinmetz, is claimed to have solved any and every difficulty anyone may have had in accepting the law of the magnetic circuit. Perhaps Mr. Sprague will become more wholly converted to our views as time goes on. He knows that long before the term "magnetic circuit" was accepted as it is now, we strenuously upheld its reality. Ohm unmistakably gave us his law, and as unmistakably must the credit of insisting upon Ohm's law as applicable to the inductive circuit be given to F. C. Webb. Had Webb's book appeared 10 or 15 years later than it did, it would have been universally applauded. As it was, it served for waste paper, and the man's name is never heard except when some of his old friends insist upon his recognition. If proof were wanted as to the utility of adapting Ohm's formula to the magnetic circuit, it is forthcoming from the fact that every practical man connected with dynamo design uses it.

But were this paper as bulky as a quarterly review, it would not give sufficient room to touch upon all the controversial points which scintillate through these pages. It must suffice then if we give—as is the object of such notices as these—a fair idea of the contents of the book. The contents are divided into 15 chapters, and may be said to be in two divisions; the first eight chapters dealing more especially with theory, then follow six chapters on various applications, the fifteenth being on definitions and explanations of terms, concluding with a good index. It is in the first few chapters that Mr. Sprague's idiosyncrasies crop up largely, the practical part, however, being intensely practical, and in electrolytic work, for example, containing a large amount of information not to be found elsewhere. The first chapters deal with the different forms of electrical phenomena and measurement. Our references to this part will take all the space we can spare, and on the point we cannot go with Mr. Sprague. No doubt, logically, he might compel our adhesion, but expediently, no. We refer to his desire to expunge the term "resistance" and put in its place "capacity." He says, "Resistance is the arithmetical reciprocal of the conductance of the circuit—*i.e.*, of its capacity to permit the action we call current. Resistance becomes intelligible when thus considered, although it is an altogether different thing from what the term means in mechanics; the conception will be clear if we consider a conductor not as a whole, but in its components, as if built up of a number of unit conductors, all alike, side by side, and each passing equal current—that is, each having *unit capacity*, and offering *unit* resistance in the true sense of friction." This is all very well and very true, but it helps nobody to a better understanding of electric phenomena, and there is such a great desire nowadays for everyone to tinker at nomenclature, that unless it is to be revised once for all for a quarter or a half century, authors should be chary of introducing new terms. We will say nothing of conductance, voltance, and the terms first suggested, we believe, by Mr. O. Heaviside, for the simple reason that they are in a kind of half-and-half way already adopted.

In all these chapters there is a vast amount of information given, and given in a manner at once exhaustive and convincing that cannot be obtained elsewhere. The student of "mind" by carefully examining Mr. Sprague's original articles, and the various editions of his book, would have a capital study of "mental activity." In every case there is an obvious effort to delve to the bottom of things so far as a knowledge of older and more modern researches enables one to go. What is said is said after experimental test, and only adopted when so tested. We commend Mr. Sprague's theories, and his abundantly practical information, to every electrical student. The book is one which, whether we agree with its conclusions or not, ought to be carefully read and studied by every man who professes a desire to know something about electrical matters.

ELECTRIC LIGHTING OF SMITHFIELD MARKETS.

The function which the Lady Mayoress will perform to-day will be an exceedingly interesting ceremony. That event will be the formal inauguration of the electric light installation at the East, West, Poultry, and General Markets, known as the Central Markets, Smithfield. It will be remembered that some time ago Messrs. Julius Sax and Co. proposed to the Corporation of London to erect plant for the supply of electric light to the shopkeepers in these markets at a rate equivalent to that paid by them for gas illumination, and also to erect general lamps for lighting the avenues free of charge. That suggestion was accepted by the Corporation of London, and the company in question were commissioned to carry out the work, which is to-day partially completed. The temporary plant has been erected on a large space of vacant ground which Messrs. Sax and Co. have acquired immediately on the northern side of Charterhouse-street. This plant is arranged at a depth of no less than 40ft. below the street level, at the side of the arch or arches running over to the other side of the markets. It comprises a Davey-Paxman locomotive type boiler, and an engine of 50 h.p. by the same makers, driving an Elwell-Parker continuous-current dynamo, giving 200 amperes at an E.M.F. of 100 volts. From an improvised switchboard the current passes, by means of mains carried under one of the arches, straight to four distributing-boards erected in the markets. These boards, one of which is arranged in each market, distribute the current to some of the lamps in the various shops and avenues, and will eventually distribute it to all the lamps. Before proceeding further with this brief description, it may be as well to mention that, on the same site as that of the temporary plant, a permanent generating station will shortly be erected. This station, which will be built at the side of the Metropolitan Railway, which passes it, will have a separate set of rails leading up to it, so that the coal trucks for the supply of the furnace may be run direct into the generating station yard. This station, similarly to the temporary one, will be arranged 40ft. below the street level. This arrangement allows of the mains being laid conveniently along the arch into the markets, and thus avoids tunnelling. The station will contain six Davey-Paxman locomotive type boilers, six triple-expansion engines of 200 h.p. by the same makers, and six Elwell-Parker direct-current dynamos, each of 200 units.

The latter will be coupled direct to the engines, the E.M.F. being, as in the case of the temporary plant, 100 volts. This plant will supply no less than 8,000 incandescent lamps, ranging in power from 16 c.p. to 50 c.p., and this number has already been wired. To-day, 500 incandescent lamps of these varying powers will be started, 100 of which are of 50 c.p., and which are supplied by the company to the Corporation of London for the illumination of the avenues. Of these, 25 lamps are arranged in each market. As already stated, a switchboard has been erected in each market, at a

height of about 25ft from the ground, so as to be out of the reach of meddlesome persons. Two distinct circuits lead from each board. The 100 Corporation lamps, or rather the 25 in each market, are switched on and off by means of a novel arrangement. This consists in connecting the switch to a lever attached to two chains, which have rings at their lower ends. When it is desired to switch these lamps on or off, an employé, with a long pole having a hook at its upper end, simply pulls down either chain, thus extinguishing or putting on the current. The lamps in the shops are switched on or off from the same boards by means of keys, which are used by the employés, who reach the switchboards by means of ladders. The 100 lamps belonging to the Corporation are, as already mentioned, of 50 c.p., and these will be lighted to-day. They are suspended over the avenues in the four markets by means of wrought-iron piping carried on the cross beams, the leads passing through the piping, to which they are conveyed in ordinary wooden casing; the leads for the shops are similarly run. The lamps in the latter are partly arranged under the ceilings of the shops and partly outside, the leads from the casing being run to the lamps in wrought-iron piping. These lamps are throughout arranged in clusters of three, forming a lantern, which the company call "fairybeads." These lanterns have corrugated glass reflectors, gilded to throw yellow rays of light on the meat, whilst the avenue lamps have silver reflectors. This wrought-iron piping is, we may mention, completely insulated from the horizontal girders, from which much of it is suspended by means of ebonite washers and bushes. It is not intended to use any arc lamps, and the incandescent system is carried out on the simple parallel system, which, we are informed, is arranged so as to be capable of being converted at any time into the three-wire system.

The contract which Messrs. Sax and Co. have with the Corporation is for 21 years, the 100 50 c.p. lamps are supplied free of cost, and the current will be paid for by consumers at a rate equivalent to that which they paid for the same amount of gas light last year, but, if desired, payment can be made by meter.

THE ELECTRIC LIGHTING OF DANGER BUILDINGS.*

BY CHARLES FREWEN JENKIN, B.A., A.M.I.C.E.

The danger from ordinary electric lighting, carried out in accordance with such rules as those drawn up by the Phœnix Fire Office, will soon be able to be estimated from the statistics of the fire offices. It is probably very small, but is certainly not non-existent; and it must be remembered that for every fire of sufficient magnitude to come under the notice of a fire office, there must be many trifling cases of fire, overheating and sparking, any one of which would be sufficient, in a dusty powder building, to cause a disastrous explosion.

These considerations show the necessity for taking much greater precautions in danger buildings than in others. At the same time, the danger arising from electric light varies immensely in different classes of buildings, all of which may come under the definition of "danger buildings" as given in the Explosives Act. Probably the most dangerous buildings are those used for some of the processes of gunpowder manufacture, such as granulating and pressing.

This paper contains a description of the system of electric lighting, devised by the author, adopted in some of the danger buildings of this class, at the Royal Gunpowder Factory, Waltham Abbey. At that factory, as is often the case, the powder buildings are spread over a considerable tract of low-lying ground, covered with trees, and intersected with numerous water-channels. The trees are valuable as screens in the cases of explosion, and the water furnishes both motive power and safe means of transport. The buildings are light brick and wooden structures, partly surrounded, as a rule, by heavy traverses, designed to prevent an explosion from being communicated to the other buildings in their neighbourhood. Inside is the machinery. In "dusty buildings," when the machinery is at work, the whole house is filled with a cloud of powder dust, which settles over everything, and issuing from the doors and windows, covers the outside of the buildings and ground in the vicinity with a thin layer of explosive dust. In "non-dusty buildings" there is comparatively little dust, though there is in most machine houses enough to cover the interior with a considerable sprinkling, but not enough to cause any appreciable quantity to settle outside the buildings. In both classes of buildings there is always a considerable quantity of powder undergoing the process of manufacture. The layer of powder dust is sufficient to transmit ignition from any point within the limits of the "dusty area" where it may originate to the bulk of the powder in the building. The powder dust, then, is the chief cause of the danger, since the least spark, or other cause of fire, occurring within the "dusty area" will cause an explosion of the whole of the powder in the building. The distinction between dusty and non-dusty houses has been long recognised, but having regard to the precautions necessary to make electric light safe, the author slightly rearranged the classification according to the following definitions.

Dusty houses are those in which the operation carried on produce such an amount of dust that the outside of the buildings and the ground in the neighbourhood may become covered with a layer of dust sufficient to communicate any fire occurring within the dusty region to the interior of the building. The following buildings at the Royal Gunpowder Factory are classed as dusty houses: dusting houses, granulating-houses, breaking-down houses, press houses.

The neighbourhood of a dusty house—namely, the whole area over which explosive dust may collect in sufficient quantity to be dangerous—has been called the "danger area." (See Home Office "Memorandum on Electric Lighting of Factories and Magazines for Explosives," December 31, 1891.) The boundary of this area is necessarily indefinite. It depends on the rate at which dust escapes from the building, the nature of the ground, the climate, and particularly on the length of the longest spell of dry weather which may be expected. At Waltham, the author having consulted with the men of longest experience in the [illegible] fixed the boundary of the danger area at 50 yards from the nearest part of the building.

Non-dusty houses are those where there is never a sufficient amount of dust to cover the exterior of the building or the ground in the neighbourhood. The [illegible] buildings at the Royal Gunpowder Factory are classed as non-dusty houses: incorporating mills, moulding [illegible] stoves, magazines.

I. Dusty Houses.

If it were possible to keep all the electrical apparatus outside the "danger area," it would render the [illegible] perfectly safe. But it is clearly impracticable to light the interior of the building by lamps 50 yards from the nearest part of it. It is, however, possible to keep much of the apparatus outside this area, and to protect that part [illegible] it in such a manner as to render it extremely safe.

The appliances which must be inside the "danger area" are, obviously, the lamp and the leads to it. Nothing [illegible] should be allowed inside the "danger area." And further, it is not necessary to take even the lamps inside the building, for sufficient light can quite well be obtained from lights outside the windows. Before describing the precautions which must be taken to make electric light safe, a brief list of the possible sources of danger is given.

Sparks at any point within the "danger area" arise from (1) a broken wire; (2) connection between positive and negative leads; (3) the blowing of a fuse; (4) the action of a lightning protector; (5) the opening of a switch; (6) the breakage of a lamp; (7) lightning flash.

Heat.—(1) of the lamp itself; (2) at the lampholder [illegible] at any defective joint; (4) in the leads; (5) owing to leakage or partial connection between positive and negative leads; (6) owing to leakage to earth.

In order to avoid these dangers, the following precautions should be taken.

Sparks.—(1) The wires must be protected from breakage. If there are trees near, the wires must be taken underground, or they will be liable to be broken by [illegible]

* *From selected papers of the Institution of Civil Engineers.*

branches; (2) the leads must be kept apart and well insulated, or else enclosed in a dust-proof case; (3, 4, 5) fuses, lightning protectors, and switches must not be admitted inside the danger area; (6) the lamp must be protected; (7) lightning protectors must be placed close outside the danger area, to prevent lightning from being carried to the building by the wires.

Heat.—(1) The lamp must be enclosed in an outer globe, of sufficient size to keep cool; (2) suitable lampholders must be used, and they should be protected, like the lamp, from dust; (3) joints in the wires should, if possible, be avoided; (4) the leads must be thoroughly protected by fuses; (5, 6) first-class insulation, suitable for the special conditions, should be used; great care being taken in selecting the method of support for the wires.

With these conditions in view, the author arranged the following system: The main leads, which are carried overhead, terminate at a post, situated at least 50 yards from the building to be lighted, on which is fixed the switch-box, which contains all the fuses, switches, and lightning protectors used in connection with the building. The leads from this box, consisting of a pair of insulated wires to every lamp, are carried underground through iron pipes to the lamps. The lamps, which are all outside the buildings, are supported in front of the windows on lampposts of various forms, designed to suit the special circumstances of each case. The principle aimed at in the design of these is to provide a support for the lamp entirely independent of the building. In all cases the wires are carried up to the lamp enclosed in an iron pipe, on the end of which the lamp is fixed. The pipe used is wrought-iron steam-pipe, with ordinary socket joints, coated inside and out by Angus Smith's process. It starts at the switch-box, to which it is fastened by a flange, and runs underground to the building, where it branches, as required, to the various lamps. The size of the pipe is determined by the number of wires which it has to carry. The following table shows the sizes which have been found most suitable for different numbers of lamps, each lamp having two wires:

		Inches.
Lamps 1.	Inside diameter of pipe	1
" 2.	" " "	1¼
" 3, 4.	" " "	1½
" 5, 6.	" " "	1¾
" 7, 8.	" " "	2
" 9, 10.	" " "	2¼

Cast-iron "drawing-in boxes" are placed at all the angles of the larger pipes, and the same box is used wherever the branches leave the main pipe, except that a smaller box is sufficient at the junction of the branches leading to single lamps. Drawing-in boxes are not necessary at all the bends of the smallest branches; but where they are not used running joints are provided on both sides of the bends. The insertion of these boxes at the bends and branching points greatly facilitates the drawing-in of the wires. No tees or elbows are allowed, on account of the sharp edges which are left inside these fittings. The sharp edges left on the insides of the pipes when they are cut are carefully removed before the pipes are fixed in their places. Those ends of the pipes which are screwed into the drawing-in boxes are belled out slightly so as not to catch the wires as they are drawn in. The joints are all made with red lead, including those round the lids of the drawing-in boxes.

The leads to the lamps are single No. 16 copper wires, insulated with vulcanised indiarubber and lead-covered, supplied by the India Rubber, Gutta Percha, and Telegraph Works Company, with a guaranteed insulation of 300 megohm miles. No joints are allowed in the leads; but as the wire is made in long lengths, this causes very little waste. The wires are drawn into the pipes, after they are completed, by means soft spun-yarn ropes. The boxes, though small, give ample room to bend in the bight of the wires without kinks.

The switch-box is shown in Fig. 1. It is made of teak, of watertight construction, with either a wooden or a slate back on which the switches, etc., are fixed, and a sliding wooden front. The positive and negative leads enter the box through two Johnson and Phillips's fluid insulator "leading-in pipes," on opposite sides, and are joined to the two main fuses. The fuses are in turn connected through two lightning protectors to the two main switches. From the switches the leads divide, and are joined to the two rows of single lamp fuses. The lead-covered wires are connected to the other terminals of these fuses, and pass straight down into the iron pipe, the end of which is fixed to the bottom of the box. A wooden ring is fitted round the top end of the iron pipe to preserve the wires from being cut while they are being bent into position. The earth-plates of the lightning protector are connected to the iron pipe.

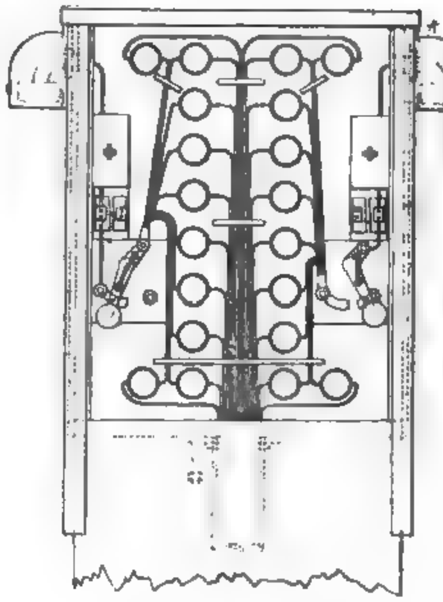

Fig. 1.

The lamp, Fig. 2, is a modification of that invented by Colonel Watkin in 1885. It consists of a cylindrical cast-iron piece, *a*, tapped to screw on to the end of the iron pipe carrying the leads and fitted with a nipple, on to which the lampholder is screwed. The outside of the piece *a* is screwed, and fits into the cast-iron piece, *b*, which forms a cover to the glass globe, *c*, to which it is attached by the copper straps, *d*. The joint between the glass and iron cover

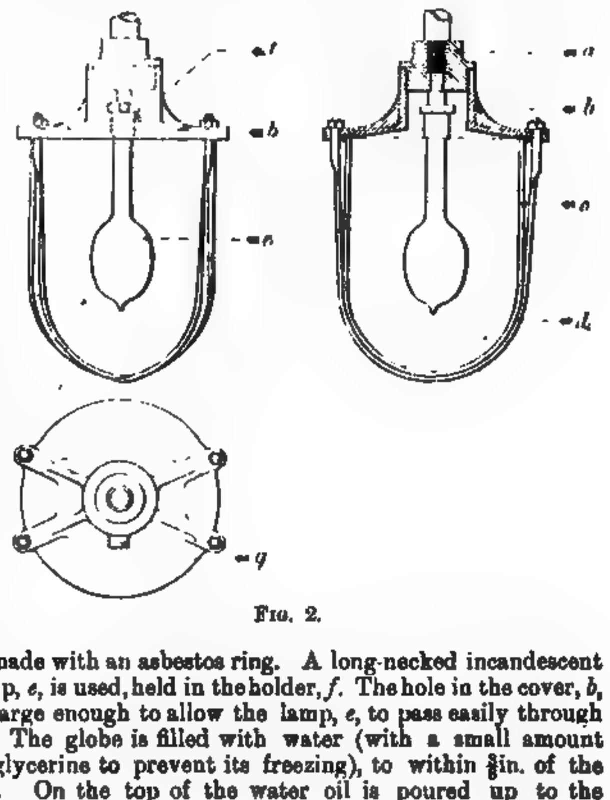

Fig. 2.

is made with an asbestos ring. A long-necked incandescent lamp, *e*, is used, held in the holder, *f*. The hole in the cover, *b*, is large enough to allow the lamp, *e*, to pass easily through it. The globe is filled with water (with a small amount of glycerine to prevent its freezing), to within $\frac{3}{8}$in. of the top. On the top of the water oil is poured up to the level of the filling-hole, *g*, which is afterwards closed with a screw. A part of one side of the globe is silvered on the outside, and the rest of that half painted with white enamel.

The details of the methods of attaching the lampholder, and leading in the wires, are shown in Fig. 3. The cast-

iron piece, *a*, is recessed slightly near the bottom; and the nipple, which is tinned, is run in with sulphur, *s*. Fitting loosely inside the nipple, and projecting above it, is the earthenware insulator, *t*, which has two small holes formed in it, through which the bare wires, *w* (the insulation having been removed) are threaded. It rests at the bottom, on the insulator, in the lampholder. Two small holes, *v*, are drilled in the sides of the lampholder, level with the top of the lamp, to allow the oil to enter and circulate. The incandescent lamp is kept cool, and dust is prevented from settling on it by the water. The oil greatly reduces evaporation, and prevents the condensation of water on the lamp cap and interior of the holder. This point is of great importance, since, if the plaster of Paris in the lamp cap gets wet, heat is rapidly generated, and the metal contacts corrode by electro-chemical action. The oil also serves as an insulator and cooling agent round the lampholder, and prevents dust from settling there. It likewise seals the asbestos joint. The object of the sulphur is to insulate the lampholder. The earthenware insulator is to preserve the insulation on the wires from the decaying action of the oil. The expansion of the water and oil with any air they may contain, and also the expansion of the air enclosed in the top of the lamp, cause the oil to rise slightly when the lamp is hot. This takes place without the oil coming in contact with the rubber insulation. The shape of the insulator is designed to prevent the creeping up of oil by capillary action.

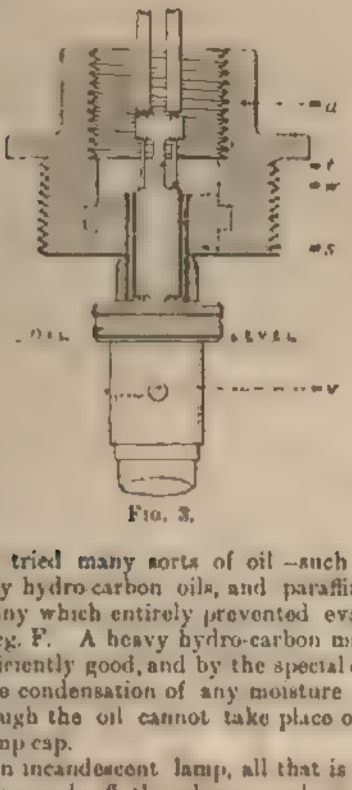

Fig. 3.

The author tried many sorts of oil—such as rosin oil, rape oil, heavy hydro-carbon oils, and paraffin wax—but failed to find any which entirely prevented evaporation of water at 140deg. F. A heavy hydro-carbon machinery oil was found sufficiently good, and by the special construction of the lamp the condensation of any moisture which does evaporate through the oil cannot take place on the wires, contacts, or lamp cap.

To replace an incandescent lamp, all that is necessary is to unscrew the cap, *b*, off the plug, *a*, and carefully lower the globe, full of water and oil. The lamp can then be changed and the globe replaced. The joint round the top of the globe is never broken, and there is no risk of spilling oil and water.

The author made a few experiments to find out what size of globe was necessary in order that no part of it should get too hot when the lamp it contained was run continuously. The maximum allowable temperature recommended by H.M. Inspector of Explosives in the "Memorandum on Electric Lighting of Factories and Magazines for Explosives," is 140deg. F. Four globes of different sizes were tested; the results were as follows:

Globe A, containing 8oz. of water, boiled in two hours.

Globe B, containing 130oz., attained a maximum temperature of 156deg. F.

Globe C, 200oz., attained a maximum temperature of 132deg. F.

Globe D, 192oz., attained a maximum temperature of 131deg. F.

The incandescent lamp in each case was absorbing 60 watts. The temperatures given are those of the surface layer of water in the globe; the temperature of the surrounding air being 60deg. F. Globe D is that adopted in the lamp above described.

A safety switching-off device is applied as follows. A weight is attached to the two main switches by a wire over a pulley, so as to open the circuit. A pull wire is run from the switches to some convenient point within reach of the building, by means of which the switches can be pulled in, raising the weight. In the event of any defect appearing in the lighting, the release of this wire will at once entirely disconnect the leads. If this wire, in course of time, breaks, the defect will show itself at once.

The author believes that these arrangements fulfil all the conditions laid down. The following points may be specially noticed: The wires are entirely enclosed in dust-tight iron pipes the whole way from the switch box to the lamps—that is, for the whole distance traversed within the danger area. The iron pipe will not only keep out the dust, but tend, in case of any short circuit, to develop it rapidly, and so to blow the fuse. There are no joints in any of the wires. The wires, being lead covered, are well protected against wet and iron rust. The drawing in of the wires is easily and quickly accomplished. The fuses are set to blow at four amperes, which is well within the safe carrying capacity of the wires, and far above the regular working current. Thus there is perfect protection, and the fuses are quite cold in ordinary work. The main fuses are only intended to act if lightning short circuits the dynamo. They are also very large for the normal current. The lamp globe, already described, affords complete protection from the danger of the lamp itself.

II. Non Dusty Houses.

In non-dusty houses, many of the sources of danger before enumerated do not exist.

Sparks.—There is no danger from sparks if they are kept clear of the building.

Heat.—There is no danger from heat if it is kept out of the building. The following precautions are then sufficient:

Sparks.—The wires need only be protected from breakage or short circuiting in the immediate vicinity of the house. The fuses, etc., need only be kept a few feet off the building. The lamp, which is necessarily very near the house, should be protected from breakage. A lightning protector should be fixed on the main leads at a little distance from the building.

Heat.—The same precautions, as in the case of dusty houses, are necessary, but only in the immediate vicinity of the building.

The following description gives the particulars of the method of lighting non-dusty houses: The main leads which are carried overhead terminate, as before, at a post situated at any convenient point near the building, to which is fixed the switch box, containing, in this case only, the two main switches, main fuses, and lightning protectors. The leads (insulated) from this box are carried overhead again on posts round the building, at about 6ft. from the outside wall. The same lamps are used, fixed, as before, on posts outside the building, in front of the windows. The connection between the leads and lamps is made as follows: One of the supporting posts for the overhead leads is fixed opposite every lamp; each of these posts carries a cast-iron fuse-box, containing two single lamp fuses. From this box a 1in. iron pipe runs overhead to the lamp, a distance of about 6ft. Branch wires are attached to the overhead leads, and carried into the fuse box, and connected to the fuses. From the fuses, two wires are carried in the iron pipe to the lamp. By this arrangement the leads are kept sufficiently far from the house to be safe, in case of their breaking; while the branches to the lamps, which necessarily approach the house more nearly, are completely enclosed, and also protected from mechanical injury. There is a fuse on every lamp, as before.

In conclusion, a few words may be said about some other classes of danger buildings. At Waltham Abbey there are, besides the powder factory, a gun-cotton factory, and a cordite factory. In the gun-cotton factory, since there is no dust and hardly any gun-cotton in a sensitive state,

no special precautions need be taken beyond those necessary in an ordinary house or factory, except that the acid fumes should be specially guarded against. Such lampholders as Messrs. Woodhouse and Rawson's chemical holder may be used. In the cordite factory, as there is no dust, the lamps may be taken inside the houses, but should be protected by suitable globes. Also the leads should be entirely enclosed. The fuses, etc., should be outside the buildings. A modification of the first system described may be used, carrying the pipes inside the buildings. The dry gun-cotton buildings should be treated like dusty gunpowder-houses.

TRADE NOTES AND NOVELTIES.

ELECTRIC TRANSFORMERS.

This invention of Messrs. Pyke and Harris's relates to high-tension transformers and other electrical power converters, with liquid insulation, in which a more or less viscous nature,

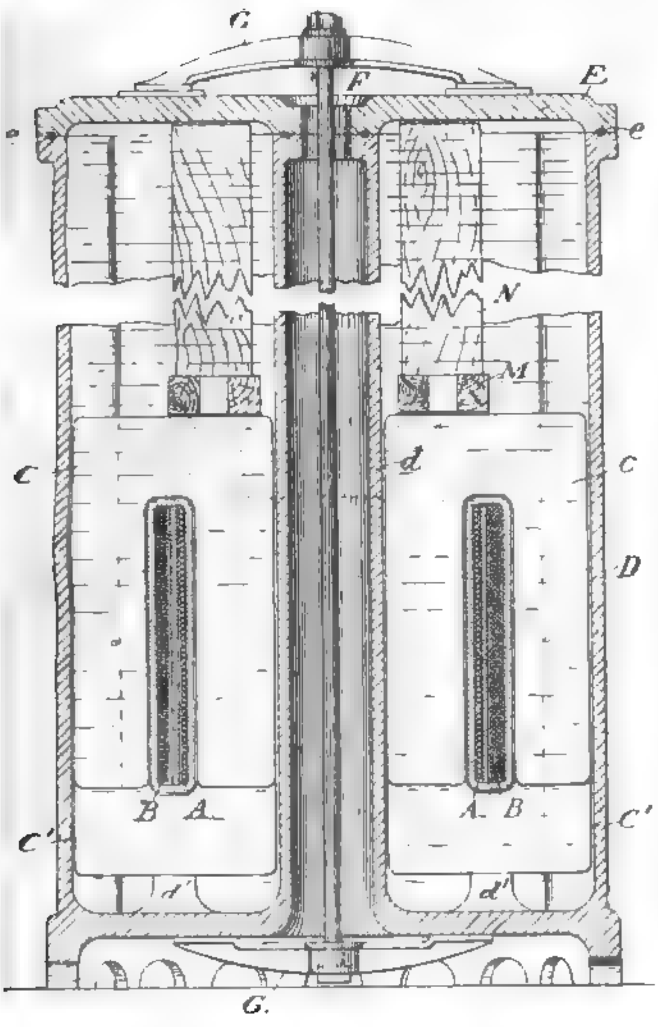

FIG. 1.

such as heavy petroleum free from all volatile distillates, is employed. The apparatus is constructed with all, or as much as possible, of the mechanical insulation of a permeable character. The transformer is placed in a container of earthenware, corrugated or provided with external ribs, serving at the same time as a cooling vessel, the height of which is about three times that of the transformer proper. The transformer consists of concentric coils of wire arranged so as to form a ring, which is arranged in sections, separated from each other by porous insulating material, which can be easily penetrated by the insulating liquid. The coils are held together by the iron of the transformer, which is arranged in saddle-pieces, placed vertically and radially, so that each set of plates enters one of the corrugations of the vessel. Each horseshoe plate encloses on each side a radial section of the coil. Each set of saddle-pieces is applied to the coil alternately from the top and from the bottom, and secured by corner bolts. The transformer has stood a very severe test, and by nature of its disposition it can be taken apart, new primary and secondary coils inserted, and the whole put together again in a very short time. Fig. 1 is a vertical section, and Fig. 2 half horizontal and half plan of the Pyke and Harris transformer. A is the primary; B, the secondary coil; C and C_1, the iron of the transformer; D, the earthenware pot serving as a cooling vessel, provided with an axial tube, *d*, reaching up to the top of the vessel; E is the lid, and *e* indiarubber packing rings placed in circular grooves between the vessel and the lid; G G are

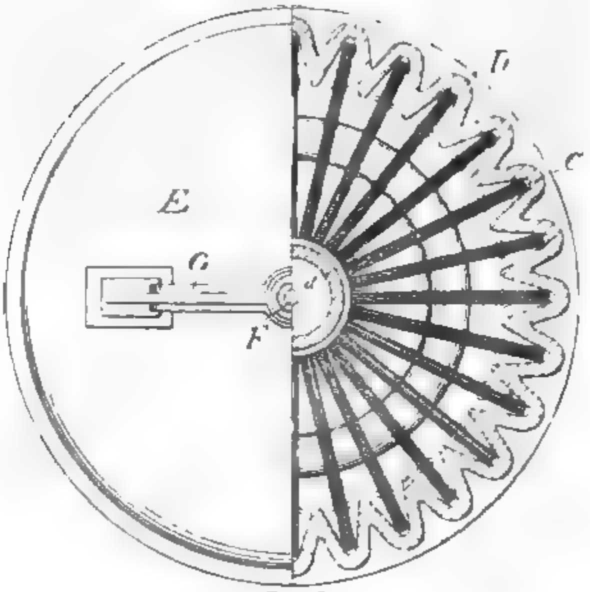

FIG 2.

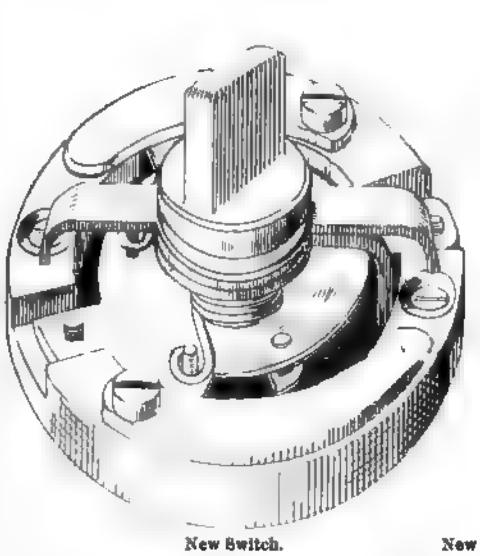
washers connecting the bolts with the vessel and lid; M is an insulating ring placed in the top of the transformer.

NEW BROCKIE-PELL LAMP.

We herewith illustrate a small globe lamp specially designed for use in shop windows and other indoor positions where little space is available. It is of the well-known Brockie-Pell type, manufactured by Messrs. Johnson and Phillips, and gives a steady light, with either continuous or alternating currents of five to 10 amperes when in parallel with 50 volts or upwards, or two in series with 100 volts and upwards, or any number in series. The first fifty of these lamps are in use at Messrs. Jones Brothers' new premises at Holloway, and we are informed are very successful.

A NEW SWITCH.

This is an automatic locking and unlocking quick-break switch, which in our opinion is superior to any which has yet been



New Switch.

New Brockie-Pell Lamp

produced. In an ordinary switch, fitted (as this is) with a spiral spring, which prevents contact being made between the break and the pole-pieces when the switch is off, the methods whereby the pull of the spring is overcome when the switch is turned on is merely the friction between the break-piece and the pole-pieces, and is, therefore, liable to break the current by slipping unless completely locked. It is also liable to arc in consequence of partial contact, but in order to obviate

these objections this switch is made. To the break piece is fitted an arm at right angles, which protrudes through the base of the switch. On the bottom of the base is attached a sliding bolt, which engages the arm when the switch is turned on and prevents the break piece from breaking contact with the poles. In order to keep the sliding bolt in position to engage the arm, a small spring is fitted in such a manner that when the arm passes the bolt the spring shoots the bolt forward; this constitutes the automatic locking arrangement. In an ordinary switch, as mentioned, the break piece is usually fastened securely to the spindle, which holds the switch handle, but in this switch the break piece is free to turn. Immediately under the break piece is fixed a circular cam to the spindle with a slot cut upon its edge of about one third of its circumference. This slot engages a pin in the break piece, so that when the handle is turned to make contact, the cam engages the pin, and causes the brake piece to turn with it, until the arm of the break piece has passed the bolt previously described. At the bottom of the spindle underneath the base is fitted another cam or small projection which engages the bolt, both these cams are fastened to the spindle. It will therefore be observed that when the break-piece is engaged by the bolt by means of its arm it cannot return to its original position without being released, and no vibration or violent jerking can remove it; albeit, the spindle is free to be turned back, and in so doing the bolt is withdrawn by means of the projection at the base of the spindle and the arm is released, and immediately this occurs the break piece flies off the pole pieces by the action of the spring connected with it. The switch is according to Richardson's patent, and is being put on the market by Messrs. Hurk and Edwards.

LEGAL INTELLIGENCE.

HOPKINSON v. ST. JAMES'S AND PALL-MALL ELECTRIC LIGHT COMPANY, LIMITED.

Alleged Infringement of Patent.

This was an action in the High Court of Justice, before Mr. Justice Romer, in which Dr. John Hopkinson, the well-known electrician and mathematician, applied for an injunction and incidental relief in respect of an alleged infringement of letters patent 3,576 of 1882 granted to the plaintiff for improvements in distributing electricity and in apparatus to be employed for that purpose.

Sir Richard Webster, Q.C., Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Hopkinson, Q.C., are for the plaintiff; and Sir Horace Davey, Q.C., Mr. Finlay, Q.C., and Mr. Roger W. Wallace, for the defendants.

Sir Richard Webster, in opening the plaintiff's case, said his client was a Senior Wrangler, a position which his Lordship would appreciate, and well known in the scientific and legal world. This, of course, did not entitle him to any privileges as a litigant, but it had some bearing on a case involving questions of patent law, with which Dr. Hopkinson was intimately acquainted. The rights under the patent in question had been disposed of by Dr. Hopkinson for a large sum, but he was still legal owner of the patent, as a trustee and was the proper person to sue for its infringement. Two inventions were covered by the patent. One only had been infringed, but both parts of the patent were attacked by the defendants, and it was open to them to say that a part of the patent claimed too much, though it was not suggested by the plaintiff that they had infringed that portion of it. The part alleged to have been infringed was that which covered an invention of great importance in electric lighting known as "the three wire system," which was used only in connection with incandescent lamps. There must in every system be a source of electricity, conductors, and lamps. This invention only related to the conductors. One of the commercial difficulties in the way of successful electric lighting was the great expense of large copper conductors, and in this respect the present inventor had effected a great saving. The three-wire system was invented almost simultaneously by Dr. Hopkinson and in America by Mr. Edison, and was applicable to the ordinary modes of generating electricity, whether by means of dynamos or secondary batteries. The pressure of the electricity was measured by volts, and there was a sort of analogy in hydrostatics, the volts being about synonymous with the pressure of the water. The quantity of electricity was measured by amperes, which might be said to be equivalent to the volume of water. The lamps used were on the multiple parallel bridge system, and the conductors, as a rule, were made of copper. A copper lead went from one pole of the dynamo and came back to the other pole. In multiple lighting there was no continuous commercial current unless the lamps were connected by bridging. Disregarding the terms plus and minus and positive and negative currents, the learned counsel said he should speak of the currents as the flow and return currents. Under the ordinary system there was an up and down bridging, as some of the lamps were off and on respectively. By putting on greater pressure Dr. Hopkinson was able to dispense with a large amount of copper in the conductors—in other words with a higher voltage he could do with less copper. When the lamps were "in series" the whole current passed through all the lamps; when they were in parallel there was a subdivision of the current. But under this old system there was not equal potentiality in the lamps. The pressure was required to be constant. Dr. Hopkinson's main invention consisted in connecting a third (middle) wire and coupling two dynamos in series, so that the middle wire only took back the balance of the current not required for lighting the lamps placed in parallel. The learned counsel then illustrated the changes in effect with the assistance of a model with miniature incandescent lamps, which he said was worked by an illustrious operator (Lord Kelvin). Under the new system the electric intensity could be doubled by adding only slightly to the amount of copper. When the lamps were turned off the balance of the current came back by the middle wire, and the illumination of the lamps left on remained unaltered. The learned counsel then went more elaborately into the details of the first invention with the aid of the specification, and said that if this part of the patent was good there was no question about infringement. There was no substance in the alleged anticipations. The second part of the patent, which was also attacked by the defendants, though it was not alleged that they had infringed it, was for the invention of a galvanometer for ascertaining in the engine room the potential at the far end of the conductor. The learned counsel then described this invention in detail, and concluded an address of some hours by saying that he attempted, without going into the matter scientifically, to explain generally what would be more particularly explained by the scientific witnesses, and that he protested against the opening speech of counsel being quoted to witnesses as if it were intended to describe the invention with absolute scientific accuracy.

Mr. Justice Romer asked how long the case was likely to last.

Sir Richard Webster said he hoped it would be finished in three days.

Sir Horace Davey said three hours ought to be enough to get rid of it, but

Mr. Justice Romer said he was not sanguine of disposing of a patent case in so short a time as three hours.

It was stated in court that no fewer than four Senior Wranglers were engaged in the case—viz., Mr. Justice Romer, Lord Kelvin, Mr. Moulton, Q.C., and the plaintiff.—*Times.*

COMPANIES' MEETINGS.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY, LIMITED.

The thirty-eighth ordinary general meeting of this Company was held on Wednesday at Winchester House, E.C., Sir John Pender, M.P., presiding. The Marquis of Tweeddale, on entering the room a little late, was warmly received, it having become known that his lordship was travelling in the Scotch express on the [illegible] especially to attend the meeting of the Company, of which he is a director.

The **Chairman**, in moving the adoption of the report, said that the gross receipts for the half year ended June [illegible] £216,988, showing a decrease compared with those of the corresponding period of 1891 of £17,[illegible], of which over [illegible] to loss on exchange, and the balance to the reduced rates [illegible] tralia. It was, however, proposed at the request of the [illegible] shortly to raise the tariffs to Australia by 6d. a word [illegible] diminish the loss arising from the guarantee arrangement [illegible] amounted to over £[illegible],000 during the first year of the experimental tariff. Personally, the Directors would have preferred [illegible] the 4s. tariff a little longer, in order that it might have been fairly tested, but as the colonies were all suffering from severe commercial depression, and had intimated that [illegible] the tariffs were increased they might have to cancel the [illegible] at the end of the second year, the Directors had had no [illegible] but to acquiesce in their views. This was the first time in [illegible] recollection that Governments had asked for the rates to be put up. The companies had generally been pressed all round to [illegible] them. He might say that when the rate was fixed at [illegible] advised the colonies very strongly to make it [illegible], the reduction being from 10s. The Company had now agreed to the [illegible] 4s. 9d., and he hoped that the traffic would be as large as [illegible] at 4s. If so, the loss would be so insignificant that he hoped [illegible] would in future go on satisfactorily, the benefit being very [illegible] in favour of the telegraphing public. The working expenses [illegible] the half year had been £79,281, showing an increase of £[illegible] over those of the corresponding period of 1891, but as the [illegible] expenses had been £9,041 more than for the same period of last year, those expenses over which the Directors had control really showed a decrease of £4,[illegible]. The usual interim dividends at the rate of 5 per cent. per annum had been distributed for the past half year, amounting to £[illegible], and the satisfactory balance of £70,271 was carried forward. [illegible] picked up cable a triplicate line had been laid between Penang and Singapore, costing £25,[illegible]. The Foochow-Shanghai section had also been strengthened during the half year by the [illegible] renewal and alteration of the line at the mouth of the Yangtse-Kiang river, where interruptions from ships' anchors were becoming frequent. The cost of this operation had been £[illegible], and with the cost of the triplicate Penang-Singapore it had been charged to the general reserve fund, which now stood at £[illegible], after they had expended £1,102,[illegible] out of revenue on cable renewals, duplications, etc., since the formation of the Company. This showed that, without increasing their capital, they had practically doubled the operating power of their system. They had really done more, because they had found out how to duplex their cables, which had given them an enormous cable power. The contract for laying a submarine cable between Acheen and the [illegible]

pany's system at Sumatra on account of the Netherlands-Indian Government had been successfully carried out, and the line had been opened for traffic. The cost of the work had, of course, been defrayed by the Government, and the line would, he hoped, eventually become a good feeder to the Company's system. They had the satisfaction to announce that the competition with which the New Zealand cables were at one time threatened by the Government of that colony had been averted, and an arrangement had been come to with the Government for reducing the charges over the New Zealand cables as follows: For inter-colonial messages, from 8s. 6d. to 2s. for 10 words; and for international messages, from 1s. to 3d. a word; the Government guaranteeing the Company against three-fourths of the risk of any loss which might arise from the reduction, the Company bearing one-fourth. The value of the traffic in question was £26,258, the Company's risk being £4,386 if no increase of traffic resulted. With an increase of 50 per cent., however—which would not be an excessive estimate for such substantial reductions—the Company's liability would be only £3,297. Their relations, therefore, with New Zealand were now thoroughly satisfactory, and he hoped that all the parties concerned would thus derive considerable benefit in the future. It had also been arranged for New Zealand to join in the Australian guarantee and receive the benefit of the cheap rates to Australia. The tariff between Europe and New Zealand would, therefore, be reduced from 10s. 2d. to 5s. 2d. per word for ordinary telegrams. The date for bringing the new tariffs into force had not yet been definitely settled, but it would probably be the 1st prox For the last 20 years the Company's relations with Queensland had not been satisfactory, and the Government of that colony had endeavoured in every possible way to oppose the Company. The sum which Queensland would have to pay to reduce its tariff to the same rate as that which prevailed in the other colonies would be only £1,000 a year. The principal reason for the hostility of the Queensland Government towards the Company was because the latter adopted another route instead of the Queensland system when telegraphic communication was first established with Australia 20 years ago. A short time since the merchants of London went in a deputation to the Queensland Minister of Telegraphs and urged upon him the desirability of his Government's joining with the other colonies in the guarantee referred to. So far, nothing had resulted from the deputation. He could only say that they had done everything possible to conciliate Queensland and to endeavour to induce the Government of the colony to take a different view. It was recently pointed out by a member of the Colonial Parliament that the inferior position which Queensland held in comparison with the other Australian colonies in this matter was prejudicial to her, and the Government were advised to put the colony on the same footing. The Prime Minister however, replied that the Government would not join in any agreement that would give any assistance to monopoly. The Government had made an agreement with another company for a cable to New Caledonia, and the Prime Minister said he thought that they would be defeating their own object by assisting this Company. He (the Chairman) believed that they had agreed to pay £2 000 a year towards the New Caledonia cable—a project from which he could not see that any benefit would result to the colony. If, on the other hand, the Queensland Government gave up the policy which they were pursuing towards the Company there was no doubt that they would very largely benefit the interests of the colony, and he had no doubt that the colonists would eventually insist upon this course being taken. In conclusion, the Chairman said he doubted whether he had been able on any former occasion to put a more satisfactory account of the position of the Company before them than he had done that day.

Mr. Francis A. Bevan seconded the motion, which was unanimously adopted.

MONTEVIDEO TELEPHONE COMPANY.

The annual general meeting of the Montevideo Telephone Company, Limited, was held on Monday at the offices, 96, Gresham House, Old Broad-street, E.C.

The **Chairman** (Mr. Herbert Ward), in moving the adoption of the report, said that during the year they had realised an increase of profit over the previous year equal to about 1¼ per cent. of their preference share capital. That profit was entirely due to economy in management. Mr. E. F. Powers had resigned the post of managing director, which resulted in a considerable saving. The London expenses had now been reduced to their lowest. The Board had earned a dividend, but they had expended the money in purchasing their central offices. The latest advice informed them that the lower portion of that property had been let for £254 per annum. Last April he visited Montevideo, and as the result of his investigations he was able to report most favourably upon the orderly management that prevailed, and also upon the general condition of the Company's property.

Mr. C. H. Sandford seconded the motion, which was adopted.

After a long discussion, the following resolution was agreed to, on the motion of Mr. Praed: "That a dividend at the rate of 3 per cent. per annum be declared upon the preference shares of the Company, such dividend to be not immediately payable, and that a committee be formed to agree with the Directors as to the best manner of carrying out or securing the payment thereof."

Eastern Telegraph Company.—The receipts for the month of October were £61,069, as against £60,784 for the corresponding period last year.

NEW COMPANIES REGISTERED.

United Electric Tramways, Limited.—Registered by Millington and Drew, 14, Great Winchester-street, E C., with a capital of £30,000 in 6,000 shares of £5 each Object: to acquire tramway undertakings in the United Kingdom or elsewhere, and to develop and work the same, either by horse, steam, electricity, or other power, and to carry on business as carriers of passengers, goods, minerals, and merchandise of every description; as omnibus proprietors, the business generally carried on by a railway company, etc.; to acquire concessions for the establishment of tramways, the installation of electric lighting or motor power, or other electrical installations, and all privileges connected therewith. There shall not be less than three nor more than seven directors; the first are to be elected by the signatories to the memorandum of association. Qualification: 50 shares. Remuneration: Chairman, £200; ordinary directors, £150 each; in addition, 10 per cent. of the net profits after payment of 8 per cent. dividend.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the week ended October 28 were £3,099.

Catalogue.—We have received a catalogue of patent dynamos from Messrs. W. H. Allen and Co., Lambeth.

Colchester.—The Colchester Council are making enquiries as to the cost of a provisional order for electric lighting.

Wolverhampton.—The tenders for Wolverhampton electric plant are required to be sent into the town clerk by Nov. 15.

Cuba Submarine Telegraph Company, Limited.—The receipts for the month of October were £34 more than for the corresponding period last year.

West India and Panama Telegraph Company.—The receipts for the half-month ended October 31 were £2,049, against £1,982, showing an increase of £67 as compared with the corresponding period last year.

New Swindon.—Mr. Morris is the member of the New Swindon Local Board who protests against the purchase of the gas works until full information is acquired as to the cost of an electric light installation, and his efforts ought to be aided by technical engineers.

Scarborough Telephones.—The Water Committee of the Scarborough Town Council have received an estimate for the establishment of telephonic communication between the pumping stations at a cost of £480, and an annual charge of £51. Further discussion of the project was postponed.

City and South London Railway Company.—The receipts for the week ending October 30 were £889 against £802 for the corresponding period of last year, or an increase of £87. The total receipts for 1892 show an increase of £1,299 over those for the corresponding period of 1891.

Staffordshire.—The Committee of the Staffordshire County Council reported at last meeting that the tender of the Electric Construction Corporation, Limited, Wolverhampton, for lighting the Werrington Industrial School by electricity had been accepted, and that good progress has been made with the work, the installation now being nearly completed.

Newport.—A sub-committee of the Newport (Mon.) Lighting Committee have been in London for the purpose of making enquiries with regard to the installation of the electric light adopted by the St. Pancras Vestry, which is regarded as the most successful installation by any municipal authority in England.

Bridgend.—A special meeting of the Bridgend Local Board was held in committee last week to consider the electric lighting question, and although the Committee was of one mind on the matter it was thought best to postpone a resolution to apply for a provisional order until the next ordinary meeting of the Board.

Chelmsford Fire Alarms.—At the Chelmsford Town Council last week it was agreed, on the recommendation of the Fire Brigade Committee, that electric bells be provided at the firemen's houses, with a central fire alarm at the Shire Hall, and that the lowest tender for carrying out the work, that of Mr. T. H. Dennis, of Chelmsford, at £41. 18s. 2d., be accepted.

Bowdon and Altrincham.—At meetings of the Local Boards interested, held on Monday evening, provisional agreements were come to with the Manchester Edison-Swan Company for the lighting of the whole district of Bowdon and Altrincham with the electric light. Powers will be taken both for streets and houses. A central station of large capacity will be put down.

Electric Schemes.—The *Western Morning News* has a long article on "Electricity as an Illuminant," noticing certain suggestive schemes in the North, more particularly in the little town of Nelson. This newspaper is very open to the advocation of progress in business, and its articles may perhaps serve as a challenge to draw forth further practical discussion of electric schemes for the West.

Pacific Cable.—The Queensland Government, Reuter says, has resolved not to join the other Australian colonies in the guarantee to the Eastern Extension Telegraph Company, by virtue of which the rates to Great Britain are greatly reduced. The reasons given by the Government for this decision are that the guarantee is calculated to interfere with the completion of the Pacific cable, and to assist a monopoly.

Crompton-Howell Accumulators.—A short time ago Mr. J. C. Howell, managing partner of the Llanelly Electric Lighting Company, secured an order from New York during his visit there to supply his patent accumulators to a New York central station, and several persons in the employ of the firm have left for New York, including Messrs. P. Powell, H. Cornish, F. Bell, T. Thomas, D. Davies, J. O'Brien, and H. Glascodine.

Russell and Co.—The firm of Russell and Co. has been formed to carry on the business of electrical engineers and contractors at 11, Queen Victoria-street, London, under the management of Lord Russell, lately of the firm of Swinburne and Co. They propose to list and supply every requisite that can be demanded for electrical work of every description, besides undertaking the contracting for supply and erection of any desired plant. The firm are about to issue a comprehensive illustrated catalogue of electrical plant and fittings.

City Lighting.—We hear that the Electrical Supplies and Fittings Company, Limited, are at the present time busily engaged in the City. Among the numerous installations that they have on hand at the moment are the Alliance Marine and General Insurance Company, Capel-court; the Royal Insurance Company, Lombard-street; Liverpool and London and Globe Insurance Company, Cornhill; Melchers, Runge and Co., Fenchurch-avenue; Ahrens and Co., Fenchurch-avenue; Farquharson, Roberts, and Phillips, Upper Thames-street; McEwan and Co., Lombard-street, etc.

Western and Brazilian Telegraph Company.—Including the amount brought forward from 1891 (£4,486. 18s. 2d.), the balance to the credit of the revenue account is £49,367. 18s. 3d., from which has to be deducted £12,489. 10s. for debenture interest and £6,610. 10s. for the debenture redemption fund, leaving £30,267. 18s. 3d., of which £14,000 has been placed to the reserve fund. This leaves £16,267. 18s. 3d. The Directors recommend the payment of a dividend of 3s. per share, free of income tax, on the ordinary shares for the half year, being at the rate of 2 per cent. per annum, carrying forward £1,062. 5s. 3d.

Heckmondwike.—The Electric Lighting Committee of the Heckmondwike Town Council reported at the last meeting that they had held an adjourned meeting on October 14, when a letter was read from the Co-operative Wholesale Society, Manchester, offering to take 600 lights at the rate of 6d. per Board of Trade unit. It was resolved to write to the different electric lighting companies asking upon what terms they are prepared to put down a plant at their own cost and supply the town with the electric light, giving the Board power to purchase the plant under an agreement at the end of a term of years. The minutes were approved.

Electric Launches.—We are pleased to learn that Messrs. Woodhouse and Rawson United, Limited, of the Strand Electric Launch Works, Chiswick, have just received an order from J. West, Esq., of The Albany, Piccadilly, for a handsomely finished electric launch, 35ft. in length, to be built in their best style, and to travel at a high rate of speed. The boat will be used entirely for pleasure purposes, and will add yet another to what is undoubtedly the best form of river locomotion. There is no doubt that the electric launch business is proving remunerative, and large number of enquiries are constantly being received by makers from all parts of the world.

Hull.—The Hull Corporation having applied to the Local Government Board for power to borrow £25,000 for laying down the first installation of electric light in Hull, Major-General Henry Darley Crozier, R.E., on 28th ult. attended the Hull Town Hall for the purpose of holding an enquiry into the matter. The proceedings were only formal, there being no opposition. The Mayor (Councillor Robson), Councillor Holder, chairman of the Electric Lighting Committee, the town clerk (Mr. R. Hill Dawe), and the borough electrical engineer (Mr. Lowis) were present. The details of the scheme were laid before the inspector, who afterwards visited the lighting station.

Lewes.—At the East Sussex County Council meeting this week, Major Edwardes will move that £200 be expended in electric light fittings for the County Hall. The following is the report of the sub-committee on electric lighting: "That, having had a consultation with the deputation of the Lewes Town Council and discussed the question of electric lighting, your sub-committee recommend that in the event of the Lewes Town Council establishing an electric lighting station or deciding to hand their powers over to a public company to be formed for that purpose, that the East Sussex County Council agree to take from them the electric current necessary to light the County Hall buildings, at a cost of 8d. per Board of Trade unit, and that the requisite fittings for the light be provided for the purpose, at a cost to be ascertained before finally deciding the question."

Leclanche Cells.—Messrs. Leclanché and Cie., of Paris, have appointed Mr. R. Aylmer, of 47, Victoria-street, Westminster, their sole concessionnaire for the manufacture and sale in Great Britain and the colonies of the well-known Leclanché and Leclanché-Barbier primary batteries. Mr. Aylmer informs us that as a guarantee the cells he supplies are genuine Leclanché batteries, Messrs. Leclanché and Cie. have accorded to him the exclusive right of using their trade mark. He sends us a catalogue of these cells, and special attention is directed to the new Leclanché-Barbier cylinder agglomerate batteries of both wet and dry type there described. These are M. Leclanché's latest patent, and are introduced into England for the first time. They have become well known abroad, and are there, it is stated, rapidly superseding all other forms of Leclanché batteries, as being by far the most efficient and economical cell yet produced.

Ammeters and Voltmeters.—It may be remembered that Messrs. Hodges and Todd were burnt out in their workshops some months ago. It did not take them long to start again, and what with the accuracy and cheapness of their instruments, added to the notice attracted to them, the firm have rapidly taken a good place in manufacturing for the trade. Business has increased, and now this enterprising young firm are, we are pleased to see, forced to move from 19, Kirby-street, Hatton-garden, to more commodious premises at 82, Turnmill-street, near Farringdon-street Station, and have largely increased their plant and machinery. The speciality of Messrs. Hodges and Todd are ammeters and voltmeters of both spring and gravity type, which they stock from 10 up to 500 amperes, and they also do a large business in manufacturing instruments, switches, and so forth for the trade. We wish them every success in their new premises.

Burnley.—The work on the Burnley central electric station has been commenced. The building will be of brick, relieved with terra cotta courses, and the boiler house will measure internally 54ft. by 48ft. It will contain two Lancashire boilers, 28ft. long and 7ft. in diameter, adapted for 120lb. working pressure, space being left for a third boiler. The boiler house will also contain fuel economisers and feed pumps. The generating room will be 60ft. by 48ft., and will contain eventually three engines of 125 i.h.p., driving three dynamos, and is to be provided with travelling cranes so as to facilitate any repairs or alterations to the machines. The station will also be fitted with a battery of accumulators from which the electricity will be supplied when the engines are not working. The distribution will be on the three-wire low-tension system, and the mains will be armoured and laid in the earth. Consumers will supply their own wires subject to Corporation regulations.

Crompton's Arc Works, Chelmsford.—The Chelmsford people are extremely proud of the electric works of Messrs. Crompton and Co., Limited, and when last week a huge new boiler was seen being drawn slowly through the streets to the works, public enthusiasm rose to a high pitch. It is an indication of the constant extension of the business of the Company. The boiler is a [illegible] steel Lancashire boiler by Penman and Co., of Glasgow. It measures [illegible] in diameter, and is of 240 h.p. It is fitted with [illegible] and water purifier, and will displace three temporary locomotive boilers. A new Willans and Robinson engine is also being [illegible]. The present machinery in the works supplies light for [illegible] 8 c.p. private lights, and the equivalent of 1,000 public lamps. The new engine is capable of supplying 3,500 8 c.p. lamps, and will therefore allow for 1,000 extension, when one of the existing engines will be also used. Space is allowed for the erection of a second large engine when the lighting requires this [illegible].

Lancaster.—The Lancaster Corporation are the owners of the borough gas works, and they have also powers under a provisional order to supply the town with the electric light. A sub-committee have been considering electric lighting projects, and have visited various installation stations in various parts of England. They have submitted a report, in which they recommend [illegible] of the low-tension system. The Brush Electrical Engineering Company, Limited, Messrs. Crompton and Co., Limited, and Messrs. Mather and Platt are to be invited to furnish the Corporation with a complete scheme and detailed specifications for the lighting of the borough, together with estimates of the cost at which they would be prepared to carry out such a scheme. The sub-committee's report was considered by the Town Council on Friday. Councillor Helme explained that the consumption of gas was advancing by leaps, and that unless the electric light was adopted a large expenditure would have to be incurred in connection with gas. The report was adopted.

Bath.—A report, which had been deferred from the last meeting, was presented in reference to electric meter testing, at the meeting of the Bath Urban Sanitary Authority last week. Its most important recommendation was that apparatus should be supplied to the inspector, Mr. J. W. Gatehouse, at an expense not exceeding £40, for the testing of private consumers' meters. At the Surveying Committee there was some opposition to this proposal. Mr. Sturges, who in moving its adoption, addressed himself to that point. The gas inspector, he said, was employed [illegible] apparatus be needed, and the expenditure proposed was sanctioned by the Local Government Board. Mr. Dyer said the [illegible] use of the gas inspector's apparatus came to the Authority, but as it was at present Mr. Gatehouse would keep all the fees. Mr. Moore said the gas inspector had a large salary, but Mr. Gatehouse was remunerated by fees. After further discussion, Mr. Sturges replied, pointing out that if they came to the conclusion that Mr. Gatehouse was overpaid by fees, they could alter the arrangement, as they had only a short time agreement with him. The report was adopted.

Leeds.—The Board of Trade have now given their formal approval of the system adopted by the Yorkshire House-to-House Electricity Company, Limited, for supplying energy under their provisional order. The system is described as a high-pressure alternating current transformer supply at constant pressure, to transformers fixed in suitable positions on consumers' premises, and the distributing mains consist of [illegible] and in cast-iron conduits under the footways where possible. The laying of these conduits is nearly completed so far as the area in the centre of the town, included in the company's [illegible], is concerned, about 5,000 yards having been laid. [illegible] applications for light are being received from owners and occupiers of premises in other thoroughfares, and this will necessitate extensions in the area of supply. The laying of mains along the route to Headingley will, it is expected, be commenced in the course of a few days. The company are meeting with an [illegible]

ingly good demand for the light, the applications already booked including almost all the leading banks, as well as public buildings, hotels, clubs, private residences, shops, warehouse, offices, etc. Strenuous efforts are being made to be ready for commencing the supply of current by the 1st of December next.

London Street Mains.—The Highways Committee of the London County Council at the last meeting reported that they had considered a notice, dated 14th October, 1892, from the Westminster Electric Supply Corporation, of intention to lay mains in South Bruton-mews, and a further notice, dated 28th October, of intention to lay mains in Ebury-street, Victoria-square, and Albert-street. The works proposed are unobjectionable, and they recommend that the sanction of the Council be given to the works referred to upon the condition that the street boxes shall be similar to those previously approved by the Council, and that the covers thereof shall consist of iron frames filled in with material to suit the paving. The Notting Hill Electric Lighting Company had given notices for mains in part of Notting Hill-square, and for mains in Observatory-gardens and avenue. The mains will be laid in three 2in. pipes, and the street boxes to be constructed will be of the pattern already approved in the previous notices of the Company. There is no objection to the proposed works, and the committee recommend that the sanction of the Council be given to the works referred to on due notice being given. They had also considered a notice from the Kensington and Knightsbridge Electric Lighting Company of proposed extension of mains in Hyde Park-gate, and agree also to these.

Peterborough.—The Peterborough Town Council have complained to the gas company "of the present and for some time past interior quality of the gas supplied by them." The company, in reply, say the gas is several candle-power above the parliamentary standard. The parliamentary standard is 14 candles, and the price is 3s. 4d. per 1,000 cubic feet. Well may the good people of Peterborough complain, in these days of electric lighting, at having to put up with 14-c.p. gas, especially at the price named. We notice also, from the local papers, that there is a well founded objection to the spoiling of the beautifully-painted ceilings in the cathedral by their exposure to the products of the hundreds of gas burners now used inside the building. The new organ, now being built for this cathedral at a cost of £4,000, will perhaps be the finest instrument in England, and electricity will be employed in its manipulation. This organ as well as the ceilings will suffer by exposure to the unconsumed carbon and other products of the great number of gas burners. We heartily wish, for the sake of this grand old monument, that those who are endeavouring to have the cathedral lighted by electricity may see their wishes carried out. We should think that Peterborough, with its compact business area, its good hotels and public buildings, and its 14-c.p. gas, would be a happy hunting ground for an electric lighting company, and the Town Council's complaint to the gas company would seem to show that any reasonable proposal, from a sound source, would be entertained by the powers that be.

Victoria-embankment and Bridges.—At the London County Council on Tuesday, the legality of the proposed electric lighting of the Victoria embankment and Westminster and Waterloo Bridges received attention. The Highways Committee reminded the Council that on 28th of June last the following resolution was passed: "That, subject to an estimate being submitted to the Council by the Finance Committee as required by the statute, it be referred to the Highways Committee to carry out, at a cost not exceeding £10,000, an electric installation with the necessary plant for the lighting of the carriageway, footways, and parapet wall of the Victoria-embankment, and that the Highways Committee do also confer with the Bridges Committee and the Parks Committee respectively, and report whether the plant can be established on a sufficient scale to enable Westminster and Waterloo Bridges and the Embankment gardens to be lighted from the same source." Upon the estimate being considered by the Finance Committee, doubt was expressed whether the Council could undertake the installation without first obtaining parliamentary powers for the purpose, and also whether the Council had power to erect works on the land under the Charing Cross railway bridge, upon which land it was proposed to place the generating works in connection with the electric light installation. The Highways Committee have, at the request of the Finance Committee, carefully considered these points, and have taken the opinion of counsel upon them; and the result is that they have come to the conclusion that, in order to prevent any risk of the action of the Council in this matter being called into question, it is advisable that the Council should obtain parliamentary powers to carry out the proposed installation. They accordingly recommended that it be referred to the Parliamentary Committee to take the necessary measures to obtain the sanction of Parliament in the next session, to the carrying out of the electric light installation on the Victoria-embankment and the Westminster and Waterloo Bridges. This was approved.

Belfast.—At the Belfast City Council meeting on Tuesday, Alderman Johnston proposed that the minutes of the meeting of October 13, so far as they referred to the question of electric lighting, be confirmed. Mr. Kelly seconded. Mr. Wellington Young said he had heard of what took place at the meeting yesterday. If he had been present at that meeting he would have voted against the proposal to accept £4,000 for the first seven years, and £5,000 for a second term of seven years. Mr. Masterson called Mr. Young to order. Mr. Young said he only made that statement in order to ask if there would be an opportunity of discussing the question. The Lord Mayor: Certainly. Mr. M'Cormick said he thought that the installation should be five times as large, and he would move that the minutes be amended by the insertion of 50,000 lights in place of 10,000 lights. Mr. R. Wilson seconded. Mr. Lindsay asked what powers had the Council of charging for the light, or of compelling its use. The city clerk said the Corporation had power to charge up to 8d. per unit. Mr. M'Cormick said he had advocated this installation three years ago. In Bradford an installation of 30,000 lights was put up, and there the demand was speedily more than the station could supply. What had taken place in Bradford he had no doubt would take place in Belfast, which was an equally progressive city. Dr. Steward supported. Mr. Andrews asked if there was anything in the provisional order that limited the extent of electric lighting. The city clerk said there was no limit. Mr. Masterton asked if there was any advantage in having a small installation; if it were cheaper to have a larger one than that proposed he would go for it. Alderman Bates pointed out that the installation proposed was an initial one. Mr. Ritchie spoke in favour of district stations. There was a loss of voltage by having a large central station equal to 5 per cent. every 100 yards. Alderman M'Connell asked what fund the money would come from. The city clerk said there was a balance of £70,000 on the gas account which could be utilised. Alderman M'Connell said he understood that it was not at present proposed to light the streets, the lighting proposed to be put up at once was for private purposes. After some remarks from Mr Robert Wilson and Mr. F Curley, Mr Wellington Young said most of them knew but little about electric lighting. What many of the public knew about electricity had been gained through the columns of a newspaper—he referred to the *Belfast Evening Telegraph*, which had given a great deal of attention to the question lately. The amendment was then put to the meeting, and lost by 20 votes to 11. Mr. Robert Wilson moved that the 10,000 light be increased to 25,000. Mr. Bennett seconded. The city clerk pointed out that it was not intended to start lighting the streets, because the cost would be three times that of gas. If the Gas Committee were instructed to light the streets with electricity they would carry out the directions. This further amendment was defeated by 21 votes to 7, and the motion of Alderman Johnston contemplating the establishment of plant for 10,000 lights was passed. The Council afterwards received a deputation from Cromac Ward to protest against the erection of further gas works, and to urge the establishment of electric light works.

Glasgow Tramways.—The conclusion arrived at by the writer in the *Glasgow Herald* who has been giving a series of articles on the tramway motor question is that horses should be abolished, cable should be used in the crowded streets, and electric traction in the quieter suburbs. The Tramway Trust seem to be intending to make a fair beginning, and have recently advertised for the equipment of certain quieter routes on the trolley system. They have been in communication with the Thomson-Houston system, and other firms will no doubt have a chance. Two routes are being proposed for experimental lines—one from Mitchell-street to Springburn, with a branch to Maryhill, 6¾ miles of double track; and the other to Springburn and Dennistoun, from St. Vincent-place only. The tube pole, he thinks, should not be used, the Milliken lattice-pole being far preferable. The *Herald* continues: "Whatever firm or company the Corporation employ to equip the electric lines, it would be well to get the firm either to guarantee that the working expenses shall not exceed a certain sum per car mile—say, for the first three years—or else get the firm to work the routes for such a period of time for a fixed remuneration. This would at once test exactly what the electric men are prepared to do in this country. It will be remembered that the Town Council got a guarantee for accumulator traction, and even with that they have not yet adopted it. The accounts, of course, should be under the superintendence of the Tramway Trust's accountant. In passing, we would say that the Trust should not definitely abandon all thoughts of electric accumulator traction. The enormous advantages of that system for quiet level routes, and in residential districts where no other system is practicable, have frequently been emphasised, and they should not be forgotten. We have mentioned some reasons for the especially bad results in Birmingham, and we think many of the causes are avoidable. The Electric Power and Traction Company of London still adhere to their offer to run accumulator cars at a haulage charge of 4½d. per car mile in Glasgow, or nearly 1½d. per car mile less than horse haulage presently costs. This is a guarantee, and cannot be lightly pooh-poohed. The stoppage of their small installation of cars in London has really nothing to do with the question. The cars were run to give the company information upon which to base contracts and offers, and that information having been got, their purpose was served. We therefore hold, especially in view of improvements always going on, that the Tramway Trust should not lose sight of the Electric Power and Traction Company's offer. Perhaps the Trust's hands will be full enough meantime with other work, but the turn of the accumulator ought to come. In this connection it should also be noted that the Electrical Power Storage Company, who manufacture accumulators, have now begun to advertise that they are prepared to undertake the maintenance and working of approved tramways equipped with self-contained electric cars at rates from 55 to 65 per cent. of the gross receipts. This is so good an offer that tramway authorities cannot afford to ignore it. It means a working expense of from about 10 to 20 per cent. less than the cost with horses. Glasgow has many lines suitable for accumulator traction, so that the Trust ought really to reconsider the matter. Enquiry can do no harm, and possibly Birmingham experience may only be a stepping-stone to success. We believe the idea of the Trust at present is that they can be getting the power station erected for the trolley wire lines, the machinery placed, and the poles set up, so that when the tramway company's lease expires in 1894 the electric line may be started with little delay. But the same course is open in regard

to the cable system. It appears that the Trust are still somewhat dubious as to the initial cost. In the end of last year the Tramway Committee obtained from Messrs. Dick, Kerr, and Co., the constructors of the London and the Edinburgh cable lines, an estimate of the total cost of constructing and equipping five miles, double track (equal to 10 miles single), on the cable system. The estimate was as follows:

Track, tube, and pulleys complete	£85,000
Engine room, machinery, stable, etc.	9,250
44 gripper cars (dummies)	5,280
Total	99,530

This included track rails and the causeway setts. If the Corporation supplied these the estimate would be reduced to £79,530. It did not include land. The same firm have just put in an estimate for another town for the conversion of 2½ miles, double track, from steam to cable. The equipment includes 20 large bogie cars with grippers on the platforms, and the estimate, including engine and boiler house, etc., complete, is £53,000. A large proportion of the existing track rails and setts will be used again. Now both here and in the case of the Glasgow estimate there is further proof that the cable system costs very little more than a horse installation for a heavy traffic, such as a car every two minutes. All who sympathise with the solid claims of cable traction will be glad that the Tramway Trust are seriously thinking of giving it a trial. We are convinced that with wise engineering, construction, and management nothing more is necessary, and we look forward to the time when Glasgow will have a system of cable roads comparable to some of those in America. We have dealt with the present position of the electric accumulator system in England. We have shown the great success of cable traction at home and abroad. The more or less dubious condition of electricity with the overhead wire for a fair traffic, together with its low first cost and efficiency as far as experience goes for suburban lines, have been pointed out. Its absolute unsuitability for heavy city work has been demonstrated. The position and prospects of mechanical power for British tramways have been sketched, and a glance has been taken at new inventions. The work to be done in making a change to the electric and the cable system has been indicated. All these studies point unmistakably to one conclusion, which may be briefly expressed in the phrase—cable for the city, electricity for the suburbs."

PROVISIONAL PATENTS, 1892.

OCTOBER 24.

19025. **Electricity meters and improvements therein.** Arthur Wright, 26, Park crescent, Brighton.

19061. **Electric railway systems.** William E. Irish, 9, New-inn, London. (Complete specification.)

19062. **Improvements in means or apparatus for enabling electric current to be derived from an incandescent lampholder and conducted to a lamp or other electric apparatus at a distance therefrom.** Sidney Alfred Hunter, 23, Southampton buildings, Chancery lane, London.

19076. **Improvements in or relating to microphone carbons.** George Septimus Hooker, 27, Martin's lane, Cannon street, London.

19077. **Improvements in or connected with mains or conduits for electric cables.** Joseph Aird, 27, Southampton buildings, Chancery lane, London.

OCTOBER 25.

19127. **Improvements in electric arc lamps.** George Joseph Philpott, 48, Gloster road, Brighton.

19146. **Improvements in insulators for electrical and other purposes.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (Johns Pratt Company, United States). (Complete specification.)

19169. **Improvements in or connected with telephone receivers.** William Phillips Thompson, 6, Lord street, Liverpool. (George Vaughan Benjamin, United States.) (Complete specification.)

19170. **Improvements in the production of chlorine soda, and other products by electrolysis, and in apparatus employed therein.** Henry Blackman, 55, Chancery lane, London.

19172. **Improvements in electrical apparatus for lighting and extinguishing gas lamps, and for indicating automatically whether the gas is lit or extinguished.** Axel Orling, 4, South street, Finsbury, London. (Complete specification.)

19184. **An improvement in incandescent electric lamps.** Oliver Imray, 28, Southampton buildings, Chancery lane, London. (The Westinghouse Electric and Manufacturing Company, United States.)

19194. **Improvements in telephones and in the application thereof to railway signalling.** Charles Langdon Davies, 24, Southampton buildings, Chancery-lane, London.

OCTOBER 26.

19222. **An improved apparatus for the production of electric currents, alternating in direction with great frequency.** David Salomons and Lazarus Pyke, 33, New Tothill street, Westminster, London.

19220. **Improvements in electric batteries.** Edwin Freund, 63, Queen Victoria street, London. (Ernest Freund, Austria.)

19236. **Improvements in and relating to the generation and distribution of electrical energy.** George Wilkinson, Mansfield House, Southport, Lancashire.

19242. **Improvements in cases for containing electric batteries and the like.** Alfred Oblasser and Charles Terry, 43, Southampton buildings, Chancery lane, London. (Date applied for under Patents Act, 1883, section 103, 2nd April, 1892, being date of application in France.)

19248. **Improvements in conduits for electrical conductors.** Charles Edmund Webber, 70, Chancery lane, London.

OCTOBER 27.

19282. **An improvement in or connected with galvanic batteries.** William Walker, 128, Colmore row, Birmingham.

19293. **Improvements in electric lock and alarm.** Robert Baumann, 52, Chancery lane, London. (Complete specification.)

19303. **Improved means for transmitting telegraphic signals through submarine and like cables.** Edward Henry Draper, 124, Chancery lane, London.

OCTOBER 28.

19385. **Improvements in or relating to the distribution of electrical energy and in maintaining the potential thereof.** William Lowrie, 433, Strand, London.

19386. **Improvements in or relating to the supply of electrical energy for propelling or lighting purposes upon electrical railways.** William Lowrie, 433, Strand, London.

19387. **Method of increasing the speed of signalling in submarine or subterranean cables, and the construction of such cables for this purpose.** Siemens Brothers and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Messrs. Siemens and Halske, Germany.)

19393. **Improvements in electric battery apparatus.** Thomas Froggatt, 55, Chancery lane, London.

19404. **Improvements in or relating to safety cut outs for electric generators, transformers and motor generators coupled in parallel.** John Smith Raworth, 6, Lincoln's-inn fields, London.

OCTOBER 29.

19451. **Improvements in voltaic batteries, electrodes, and connections.** Henry Francis Joel, 44, Lavender grove, Dalston, London.

19478. **Improvements in electrical apparatus for increasing the adhesion of the wheels of engines on railway rails.** Adrien Palaz and Victor Duboux, 45, Southampton buildings, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1891.

17220. **Commutating electric currents.** De Ferranti.

18256. **Electro deposition of metal upon the surface of glass, etc.** Ford. (Pottier.)

19020. **Telephonic switching apparatus.** Bennett.

20545. **Telephonic exchange signalling.** Bennett and McLean.

21018. **Electric arc lamps.** Schmidt.

21154. **Electrical lampholders.** Snell and others.

21246. **Dynamos.** Munro.

21399. **Secondary batteries.** Lake. (Müller.)

22404. **Coupling electric mains.** Bowden and others.

22695. **Electrical circuits.** Imray. (Westinghouse Electric and Manufacturing Company.)

1892.

11320. **Telephonic apparatus.** Vogt.

11426. **Electric switches, etc.** Dymond. (Strowger and another.)

13380. **Telegraph cables.** Bedwell.

15179. **Arm rests for telephone operators.** Bailey and others.

15833. **Telegraphic apparatus.** Thompson. (Bell.)

15864. **Electrical switches.** Atkinson.

NOTES.

Antwerp.—The contract between MM. Van Rysselberghe and Moris and the town of Antwerp was signed last week.

Swiss Telephones.—The length of the wires used by the various telephone systems in Switzerland is given as 13,340 miles.

Personal.—Mr. Sidney Hargreaves, consulting electrical engineer, is leaving for the Cape for the winter on account of ill-health.

Tempered Copper.—Over 500 different patterns of commutator bars and segments are now made by the Eureka Tempered Copper Company of America.

Degrees.—The course in electrical engineering is now acknowledged as part of the work leading to the Ph.D. degree in physics at the Johns Hopkins University.

Indian Telegraphs.—The Government of India have sanctioned the construction of a line of telegraph from Srinagar to Astor, by way of the Stragbad and Burzil passes.

Electric Railroad.—Mr. H. Ward Leonard is busy constructing an interesting electric railway for passengers and heavy goods traffic between Johnstown and Gloversville, New York.

Electric Motors.—Prof. Crocker, who has means of judging, says there are between 50,000 and 100,000 electric motors now in use in the States, as against about 1,000 only in the whole of Europe.

Belgian Exhibition.—The proposal, it is stated, has now been definitely adopted to hold the Belgian International Exhibition of 1895 in two sections—the one at Brussels and the other at Antwerp, the two parts being connected by an electric railway.

Berlin.—A report by Herr Cuno states that Berlin is now lighted by 2,916 electric arc lamps and 67,459 incandescent lamps. In addition to these there are 253 private installations—170 driven by steam and 83 by gas—which supply 3,287 arc lamps and 40,801 incandescent lamps.

Terrestrial Magnetism.—A French officer, M. Ribard, propounds his theory that the terrestrial magnetism is due to earth currents engendered day by day by the solar heat travelling round the globe, and that these currents being from east to west produce the magnetic effect.

Stealing Lamps.—The Southend piermaster has evidently been troubled with purloiners of incandescent lamps, for he reported at the last Board meeting that, amongst other articles missing, he had found 10 incandescent lamps missing from the wings, two from the lavatories, and five from the orchestra.

Meteorology.—At the meeting of the Royal Meteorological Society on the 16th inst., a paper will be read on the "Thunderstorm, Cloudburst, and Flood at Langtoft on July 3," by John Lovel, F.R.Met.S., and "On the Measurement of the Maximum Wind Pressure, and Description of a New Instrument for Indicating and Recording the Maximum," by W. H. Dines, B.A., F.R.Met.S.

Niagara.—Among the plans under consideration for the electrical transmission of power from Niagara are those of the Oerlikon Company; Brown, Boveri, and Co.; the Compagnie de l'Industrie Electrique, of Geneva; the General Electric Company, of New York; and the Westinghouse Company, of Pittsburg. No decision as to the system to be used has yet been definitely made.

Graphite.—If engineers knew all the good qualities of graphite, there would be twice the demand, thinks a technical correspondent. Mixed with oil drippings and smeared on bolts it effectually prevents rust even in the dampest places, but the graphite must be of good quality. It may be used for pipe joints, cylinder heads, and piston-rod packing, besides the lubrication of bearings.

North-East Coast Engineers.—On Saturday, a general meeting of the North-East Coast Institution of Engineers will be held in West Hartlepool, when papers "On the Combustion of Coal and Prevention of Smoke" will be read by Mr. J. R. Fothergill, vice-president; and "On a System of Mechanical Aid to the Investigation of Speed Curves," by Mr. J. Denholm Young, Wh.Sc.

Aluminium.—The Aluminium Company will soon have to change its name to the Sodium Company, it would appear. The trade in aluminium has been entirely revolutionised by electricity, and instead of selling at 20s. a pound, this metal is now supplied at 2s. The company have gone in for the production of sodium at their Oldbury works, and have been sufficiently successful to induce them to extend the works.

Rival Illuminants.—The chairman of the Southampton Gas Light and Coke Company, at the half-yearly meeting last week, said the company were not at all afraid of the electric light; the fact that they had increased the sale of gas by 4,500,000 cubic feet during the half-year proved that it had not injured them, and it appeared to him it was only one illuminant added to those already in use, and that there was plenty of room for all.

Southend Pier.—The Southend Committee have recommended that a sum of £5 should be divided between the two drivers of the electric cars on the pier for the efficient way in which they have driven the cars without accident during the season. It seems that last year there were several accidents, and the Pier Committee considered the matter, and thought it would be policy to hold out some inducement for the men to run with carefulness.

Technical Education. — An architect has been appointed by the Dunfermline School Board to prepare plans for a proposed technical school at a cost of about £4,000. A number of classes, which will be incorporated with the technical school, are at present being conducted, and it has been agreed to open a preparatory class in chemistry, and to appoint Mr. E. N. F. Hamilton, of Glasgow, teacher of steam and applied mechanics.

Trinity Engineer.—It was generally expected (says the *Observer*) that Sir James Douglass's successor as chief engineer at Trinity House would have been his son, who has aided him in several of his works, notably in connection with the Eddystone Lighthouse; but the choice of the Brethren has fallen upon Mr. Matthews, who was assistant to Sir James for many years. Mr. Douglas, however, becomes consulting engineer, with the reversion of the higher post.

Simla.—The question of lighting Simla with electric light, says the *Indian Engineer*, is under consideration, and it is proposed, if a practicable scheme is prepared, to form a company to carry it out. One of Messrs. Siemens's engineers has been examining the project for drawing the requisite power from the Sutlej; but on account of the expense this project is likely to be given up in favour of another, which would draw the power from the municipal water works.

Original Research.—The Royal Institution has received a grant from the Goldsmiths' Company "for the continuation and development of the valuable original

research which the society is engaged in carrying on; and especially for the prosecution of investigation on the properties of matters at temperatures approaching that of the zero of absolute temperature." A donation of £50 has also been received from Mr. F. D. Mocatta for carrying on investigations on liquid hydrogen.

York Courts of Justice.—The wiring of the new courts of justice at York for the electric light has just been completed for 450 lights. The work has been carried out by Messrs. Benham and Sons in a very satisfactory manner under the superintendence of Mr Sidney Hargreaves. The York Corporation are now putting down an 18-h.p. Otto gas engine to drive a Crompton dynamo, to light simply the police department, the prison cells, and fire station. The remaining portion of the building is not to be lighted until the general town lighting is complete, the tenders for which have been already received.

Train Lighting.—It is a great pity that the efforts of electrical engineers, given for so long to miners' lamps and omnibus lighting, cannot be turned seriously to tackling the problem of train lighting by separate lamps. In several cases trials have been made by the railway companies with dynamos carried on the train but these have not always achieved continued success. An instance of this is given on the Penarth section of the Taff Vale Railway, where it was found the distances between stations was too short to allow sufficient electricity to be produced to supply a good light when the train was at a standstill, and a return has been made to oil and gas.

Liverpool Overhead Railway.—The first train on the Liverpool Overhead Electric Railway was run on Tuesday, carrying the directors and their friends. The trip was very satisfactory, the behaviour of the main engines and dynamos being all that was anticipated, and the experiment indicated a very successful issue. There were present the chairman of the railway company (Sir William Forward) and the whole of the directors, as well as Mr. J. H. Greathead and Mr. Francis Fox, the engineers. The contractors (the Electric Construction Corporation, Limited) were represented by Mr. Thomas Parker, who received the congratulations of the whole of the party.

Lord Kingsburgh on Electricity.—On Monday, Lord Kingsburgh delivered the opening lecture of the Armitstead Course in Dundee, on the subject of "Electricity: Where Found, How Got, To What Ends." He was glad to learn that Dundee was to be the first large city in Scotland that would be thoroughly equipped with electric light. He hoped it would not be long before the inhabitants of Dundee would have something better to move their tramcars along than steam engines, because, in his opinion, they wanted cleaner and better power for the purposes of street locomotion. They in Edinburgh would live in hope, and he trusted the example of the city of Dundee as regards electric lighting would be very rapidly followed there.

Westinghouse Lamp.—The new Westinghouse lamp, about which so much is being said in America at the present moment, is understood to be a stoppered lamp with the holder and filament fitting into the bulb like the conical stopper of a chemist's bottle. It has been well tested, and the company promise satisfaction. This construction, it is maintained, will avoid the Edison patents, and is protected itself by the old Sawyer-Man patents, besides other newer patents owned by the Westinghouse Company. The result of this unexpected move on the part of the Westinghouse people will be watched with keen interest on this side, though there is hardly likely to be such spirited controversy between the owners of patent rights here as in the States, where already a large number of manufacturers are interested in the production of incandescent lamps.

Gas Supply to Electric Customers.—It will be remembered that the Carlow Gas Company took energetic action by refusing to supply gas to several householders who substituted electric light for gas in the lighting of their houses. Though not using the gas, they preferred to keep the meters, so as to be able to fall back upon the gas in case of a failure in the electric supply. At the Carlow Quarter Sessions the gas company brought an action against a householder to compel him to give up the meter, as it was the property of the company. The county court judge, without deciding the question that had been raised as to the right or wrong of the company refusing gas to the private consumer when he pays for what the meter registers, dismissed the case on the ground that the company had no right to remove the meter until they had first cut off the connection with their mains.

Separable Lamps.—The attention that is being drawn to the design of incandescent lamps so constructed that the filament can be removed and renewed will cause interest to be given to the new lamp of Mr. Frank Smith, superintendent of the lamp department of the Westinghouse Company. He has found that certain compounds of the alkaline with the silicon group of elements may be used to form the carrying stem. These compounds are soluble in hot water, and at the same time they have certain physical characteristics that enable them to unite with the wire under the influence of heat, making an airtight joint, and they also unite with the glass. In this way is formed a composite bulb, partly of glass, the remainder being soluble. Mr. Smith finds that the selection of the best compound depends largely on the composition of the glass. The greater the proportion of the alkali with reference to the silica, the softer will be the resulting compound. The compound, $4Na_2O.5SiO_2$, makes a perfect union with platinum wires, and will also unite with glass having a sufficiently low fusing point.

Reconstruction.—A legal point involving the meaning of the term "reconstruction" of a company came before Mr. Justice Chitty, in the High Court of Justice, last week, in the case of Hooper v. Western Counties and South Wales Telephone Company, Limited. The defendant was holder of nine £100 debentures, bearing interest at 5 per cent. These were redeemable at par in 1890, but there was a proviso that the defendant company might, at any time after the expiration of one year from the date of the debenture, redeem the debenture by giving three calendar months' notice to the holder, and paying to the holder £105 for every £100 capital secured with interest up to the date of payment. There was also a further condition that, if the defendant company commenced to be wound up "otherwise than for the purposes of reorganisation or reconstruction," the principal money secured by the debentures was to become immediately payable. The company amalgamated with the National Telephone Company in 1892, and all the debenture holders agreed to the proposed exchange except holders of £1,[illegible] among which was the plaintiff. Mr Justice Chitty took the view that the company had not undergone reconstruction, and dismissed the plaintiff's proceedings with costs.

Electric Photography.—Prof. W W Jacques, in a lecture before the German Technical Society of Boston, relates his experience in witnessing the operation of sending photographs over a wire by means of electricity. Without giving details of the apparatus employed, which he evidently believes to be genuine, he says "The laboratory consisted of two rooms. In one was an ordinary

photographic camera, a small developing-closet, and a table on which was a cubical box, having on one side a slit of sufficient size to receive a postal card. From this box two wires stretched across the room, and, passing through the wall, extended to a similar cubical box in the next room. I was given an ordinary postal card and asked to write a short note on it, and wrote, 'Good morning! How do you do?' This my friend photographed by electric light, developed, and dropped the hastily-made negative into the slit in the cubical box in the middle of the room. I went into the adjoining room, and there, issuing from the corresponding box on the table, was a piece of thin paper the size of the card, on which appeared a *fac-simile* of the words I had written: 'Good morning! How do you do?'" There would seem no reason, adds Prof. Jacques, why the sending and receiving boxes, instead of being in adjoining rooms, should not be placed one in Boston and the other in New York. The professor adds that he has spoken by telephone between Boston and Chicago, a distance of 1,200 miles. He looks with confidence to the development of a means of electric signalling between vessels at sea, and with anticipation to the discovery of a means of converting the energy stored in coal direct into electrical energy.

French Submarine Cable.—Some few particulars may be interesting of the submarine cable between Marseilles and Oran, manufactured and laid by the Société Générale des Téléphones of Calais—the first telegraph cable made in France. The core is formed of a seven-strand copper cable, weighing 48 kilogrammes (105·6lb.) per nautical mile, with the resistance, at 24deg. C., not exceeding 12 ohms. The insulating envelope is composed of three coatings of guttapercha, alternating with Chatterton's compound. The first coating of compound is placed on the copper core. The insulation weighs a minimum of 63 kilogrammes (138·6lb.) per nautical mile. After 24 hours' immersion in water at 24deg. C., the insulation test was to be between 300 and 1,500 megohms per nautical mile after two minutes of charge for both positive and negative charge, and after embarking was to be not less than 500 megohms per nautical mile. The cable was tested with 200 Daniell cells. The capacity per nautical mile was not to exceed 0·36 of a microfarad. The deep-sea part was armoured with 15 galvanised steel wires of 2½ mm. diameter; the wire to offer a breaking resistance of 78 to 80 kilogrammes, so that the cable had a breaking resistance of 5½ tons. The intermediate portion had 10 wires of 5 mm. diameter, the cable to offer a total resistance of 7½ tons; and the shore end had the same cable as the deep-sea part, covered with a serving of jute, and covered with a second armour of 11 large galvanised iron wires 7 mm. diameter, the total resistance to rupture being 22 tons. The cable was laid by the "François-Arago," on August 30th to September 3rd, the Société Générale des Téléphones thus successfully carrying out their first cable-laying operation.

City Lighting.—Complaints are being already made, we are told, in the City with reference to the charges for electric lighting from the mains of the City of London Company. We are not by any means convinced that there are fair grounds for these grumbles. The company have a great work before them, and are entitled to make conditions of use at first that may be possibly modified a little later on. It is complained that the work of installation is too much divided, and increases the expense to the consumer. The only division is between supply company and contractor. The fitting by the supply company itself is open to abuse, and has never been favourably regarded in this country. The charge of 8d. a unit is high, as things go, but every charge is high in the City; probably, however, it will eventually be reduced. The charge for meter rent is a necessity—persons would not like to take their supply without a meter. The condition that at least four lamps must be taken is evidently a wise one for a new undertaking, where the cost of laying on has to be considered, and the price for fitting for lamp and wiring complete at 30s. a lamp certainly does not seem an excessive amount. A firm who wished to save expense might do well to call in the services of an experienced expert, who for a moderate fee would arrange his lighting in 8, 16, 30, or 100 c.p., to save much expense both in first cost and in expenditure for current and lamp breakage, for this can be done to a much greater extent with electric light than some contractors are willing to believe. But beyond this we cannot acknowledge that the objections of City men to the expense of the electric light are tenable. The advantages they all know and, we hope, will soon experience.

The New York and Chicago Telephone.—The world has grown so accustomed to electrical marvels that the opening of a telephone line between New York and Chicago, a distance of very nearly one thousand miles, passes almost unheeded amongst the rush of other novelties. Even this enormous speaking distance is not the largest that has been successfully attempted, for speech has been transmitted between Boston and Chicago, a total of 1,200 miles. The noticeable feature of the New York and Chicago line was the quietness and absence of all induction and the clear-cut quality of the words, although the sound appeared only half as strong as on the short lines. The line is built of two No. 8 hard-drawn copper wires carried along parallel with each other, and transposed at certain intervals, or crossed diagonally without touching, in a kind of long spiral, creating electrical balance of induction. There are 45 poles to the mile, 35ft. high, the total number being 42,750. The distance is 950 miles, and there are 435lb. of wire to the mile, a total weight of 826,500lb. An important element in the success is the battery, which must be capable of maintaining constant high pressure for an extensive period. An improvement on the Fuller battery is used, consisting of a glass jar with a solution of bichromate of soda and sulphuric acid, made in the following proportions: Water, 10 gallons; commercial sulphuric acid, 25lb.; and bichromate of sodium, 8½lb. In the bottom of the porous cup is placed mercury, an amalgamated plate of zinc, and a saturated solution of common salt; a large plate of carbon forming the other pole. A wood cover prevents evaporation. The action of long-distance transmitters has also, it is stated, been improved by using a uniform size of carbon granules, sifted through a mesh. Chicago is shortly to be connected to Milwaukee and other cities.

Westinghouse Alternator.—A 500-h.p. alternator has been erected by the Westinghouse Company at Providence, working at 2,200 volts, with a guaranteed efficiency of 92 per cent. It is coupled direct to the horizontal engine, which runs at 90 revolutions only, and the armature, in order to comply with the new standard of 7,200 alternations, was made 16ft. in diameter. It is built up of wrought-iron E-shaped plates bolted to a heavy cast-iron flywheel. The projecting teeth are of T-shape and form pole-pieces, each tooth being surrounded by a simple lathe-wound coil held in position by insulating wedges driven in between the coils beneath the T-edges. The insulation of the machine is very high, being made safe for 20,000 volts. Any single coil can be replaced without disturbing the others. There is a small air space, ⅜in., between pole-pieces and surface of armature. The fluctuations of current

in the fields is secured by the use of two transformers placed diametrically opposite on the hub of the shaft, they are in multiple series, with the main circuit and their secondaries, one connected with a commutator on the shaft. The rectified currents thus derived varies with the load of the generator, for if the load is increased there is an additional flow of current on the mains, and a drop in the potential of the generator; the increased current sent through the primary of the transformers increases the secondary—that is, the rectified current—and as this latter is used to partially excite the fields of the exciter, the E.M.F. of both exciter and generator are raised, thus counteracting the drop on increased load. By this peculiar arrangement, an easy automatic regulation of the 500-h.p. alternator is obtained. The collecting rings are 28in. diameter. There are two sets of brushes—two for rectified and two for alternating currents. The field is supported on slides, and by means of screws can be moved along to give easy access for inspection and repairs.

Bradford Great Northern Hotel.—The Victoria Hotel, Bradford, has just been opened with some ceremony after its purchase and reconstruction by the Great Northern Railway Company, at a cost of about £40,000. From being a dingy and old fashioned hotel, it has blossomed forth into a magnificent and luxurious resting-place—one of the finest of the provincial hotels. Besides being artistically appointed and lighted throughout by electric light, some novel arrangements have been made for passengers' comfort. Among these is a mechanical apparatus for transferring luggage direct from the station to the bedrooms. Another great convenience is an indicator connected to the signal-box, which shows automatically, five minutes prior to the arrival of a train, the last station left, and the starting town—London, Liverpool, or Manchester, and so forth. The principal apartments on the ground floor include a large coffee room, a reading and writing room for general visitors, a similar room for business men, a stock-room for commercial travellers, and a billiard-room, with smoking-room adjoining. The large coffee-room has a floor of oak parquette walls panelled with a high dado of oak, ceiling treated in fancy plastering with an ornamental gold frieze, and the windows of stained glass; and the artificial lighting is by means of 83 electric lamps, each of 16 c.p. The reading and writing rooms close by and other rooms on the ground floor, including the billiard room, are similarly decorated, the billiard room being roofed with handsome stained glass. The balustrade to the staircase is of wrought iron, gilded and lacquered, and the ceiling is of a rich gold pattern. The hotel contains ladies' drawing-room, with the sitting rooms and private dining-rooms, on the first floor. There are in all 100 bedrooms, varying in size, the whole being lighted with electric light. There are nearly 600 lamps in all throughout the building, and the arrangements in every way reflect great credit on the enterprise of the railway company.

Society of Arts.—The opening address of the one hundred and thirty ninth session of the Society of Arts will be given by Sir Richard Webster, Q.C., M.P., chairman of the council of the Society of Arts, on Wednesday, November 16, at 8 p.m. Previous to Christmas there will be four ordinary meetings, in addition to the opening meeting. Mr. James Douglas will read a paper on "The Copper Resources of the United States," on November 30; and Mr James Dredge one on "The Chicago Exhibition, 1893," on December 7. At subsequent meetings, the dates of which are not yet published, papers will be read by Prof. George Forbes, F.R.S., on "The Utilisation of Niagara", Mr. Bennett H. Brough, "The Mining Industries of South Africa"; Prof. Francis Elgar, LL.D., "Transatlantic Steamships"; Prof. Frank Clowes, D.Sc., "The Detection and Estimation of Small Proportions of Inflammable Gas or Vapour in the Air"; Mr William Key, "The Purification of the Air Supply to Public Buildings and Dwellings"; Sir William Wilson Hunter, K.C.S.I., C.I.E., LL.D., "Ten Years of Progress in India"; Sir Edward N. C. Braddon, K.C.M.G., Agent-General for Tasmania, "Australasia as a Field for Anglo Indian Colonisation"; Sir Juland Danvers, K.C.S.I., late Public Works Secretary, India Office, "Indian Manufactures"; Mr. Edward J. Howell, "Mexico—Past and Present"; Mr Cecil Fane, "Newfoundland"; Mr. W. B. Percival, Agent-General for New Zealand, "New Zealand." The following courses of Cantor lectures will be delivered during the coming session of the Society of Arts: Prof. Vivian Lewes, "The Generation of Light from Coal Gas and its Measurement," on Nov. 21, 28, Dec. 5, 12; Dr J. A. Fleming, "The Practical Measurement of Alternating Electric Currents," on January 30, February 6, 13, 20; Prof W. Chandler Roberts-Austen, C.B., F.R.S., "Alloys," March 6, 13, 20; Mr. Lewis Foreman Day, "Some Masters of Ornament," April 10, 17, 24, May 1; Mr. C. Harrison Townsend, F.R.I.B.A., "The History and Practice of Mosaics," May 8, 15.

The Swiss Telephone System.—The American Consul-General at St. Gall describes the Swiss telephone system in a recent report as the best and cheapest in Europe. It is owned by the Central Government, like the telegraph system, and is under the control of the Department of Posts and Telegraphs. This has proved an advantage to the public, as the service is better and cheaper, the rates being lower than anywhere else in the world. In 1880 the first telephones were used in the country by a private company. This was at Zurich, the concession being for five years, the total number of instruments in use being only 144. Zurich only has now [illegible]. In January, 1886, the Government took over all the telephones, and in that year the profits came to 130,000f., in spite of reduced rates to subscribers and the expenses incidental to acquiring private rights. In 1887 the number of subscribers increased to 6,000, and long distance telephones connecting the Swiss cities as well as places in Germany were introduced. In 1888 the profits grew with the ever increasing extension of the system, and since that time the accounts have been merged in those of the telegraphs. The usual charge for subscribers is about £5 for the first year, £4 for the second, and about £3 thereafter. Eight hundred calls a year are allowed to each subscriber, all calls beyond this number being charged at a halfpenny each. Telegrams are received and delivered by telephone at a penny each, and as many of the telegraph and telephone offices are combined, and as many of the telegraphists are also telephone operators, the advantages and the economy are considerable. "The employés are better trained than in private companies, because their positions are secured to them, and there is a consequent natural pride in having their service good. Government responsibility, too, assures prompt attention, and, it is universally acknowledged in Switzerland, the management by the State has resulted in economy and a perfect service. Like the post and the telegraph systems of the country, the telephone system is owned by the people, and the State manages it with a single eye to the public good."—*Times.*

Henley's Cables.—The Henley's Telegraph Works Company received in 1885 the distinguished honour of the award of the only gold medal at the International Inventions Exhibition, and although this epoch-making year for electrical science is fast fading in the distance of the decade,

during which the most remarkable progress has been made in every direction, we find the celebrated Henley's Telegraph Works always keeping pace with the development of the industry. Their catalogue for October, 1892, just issued, though concise and statistical, probably contains the symbols of more carefulness, scientific accuracy, and thought than most other price-lists of articles supplied in the electric trade. It is a standing reminder of the way in which the trades depend upon one another to reflect upon the work which has to be put into this part of an electrical installation before it comes into the hands of engineers and contractors. Electrical engineers may make their own dynamos, switches, even engines, but not their own wire and cables. The company, known to all as Henley's, started in the very earliest days of telegraphy, has kept pace step by step with the demands of science and of commerce in their particular field, and the result is embodied in their catalogue of electric light wires and cables. The first class of electric light conductors is with insulation of vulcanised india-rubber taped; next, vulcanised rubber taped and braided; both types in three classes: 300, 750, and 2,000 megohms insulation resistance to the mile. The third kind of insulation is of pure rubber braided and compounded, one or more coats of pure rubber and braided, or with coat of felt and then braided. Details of the twin flexible cords are also given, as well as jointing material and wood casing. Separate lists, we may mention, are issued by Henley's Telegraph Works Company for concentric cables, lead-covered cables, steel-armoured cables, telephone cables, paraffined line wires, as well as for cotton and silk-covered wires for dynamos and instruments. The company draw the attention of those specifying for wires or cables to the importance of mentioning the thickness of both insulating material and outer serving for important cable contracts.

Allgemeine Company's Catalogue.—A very beautifully-printed illustrated catalogue has reached us from the Allgemeine Elektricitäts Gesellschaft of Berlin. This company, which is one of the best known and largest continental electrical engineering concerns, has branches at Breslau, Frankfort, Hanover, Cologne, Leipzig, Munich, Nuremberg, London, Madrid, and Bucharest. The work they undertake is generally of the largest and highest class, and comprising electric lighting, central station and other electric transmission of power, and the electric driving of machine tools, cranes, and other heavy machinery. The special types of high-speed and compound engines they employ in their installations are illustrated, as well as the various forms of dynamos and motors, types of which have been on show at their London branch, the Electrical Company, Limited, Charing Cross-road. The "Tudor" accumulator appertains to the Allgemeine Company, and is shown as used for electric lighting installations, or for tramway traction. Some very fine switchboards appear, as naturally becomes a company who have fitted up some of the largest central stations in the world, and measuring instruments of various kinds are represented. The company patronise the "Aron" meter and the Edison fuse plugs, and show a number of useful combinations of this latter. The "A. E. G." branch switch is of the quick-break type, and wall sockets of screw and plug kind, together with casing, sockets, and other fittings are illustrated in profusion. The "A. E. G." incandescent lamp is made by the company in the usual shapes and candle-powers. Arc lamps and standards, with swinging arms and other devices for lowering the lamps, illustrate street lighting, and then we come to some very interesting examples of the application of electric motors in the different branches of commercial and engineering work. Boring machines, both fixed and movable, are illustrated, and a fine full-page illustration of the company's engineering shop shows the portable boring machine in action. A lathe electrically driven is also shown, with an armature mounted as used in the works. An electric lift driven by one of the "A. E. G." motors, a huge electric carrying crane, and, finally, an electric discharging crane on the dockside, complete an illustrated review of work carried out by the Allgemeine Company which is an important demonstration of the extent of their productions in heavy electrical engineering.

Electric Lighting in Belfast.—Mr. John H. Greenhill, M.I.E.E., delivered a lecture, which was greatly appreciated, on "The Subject of Electric Lighting," in Belfast last week to a large and influential audience. The subject is a burning one in Belfast, and the lecturer was supported by Mr. Jas. Perry, C.E. (brother to Prof. Perry), Mr. J. Milne Barbour, and others, while the chair was taken by Prof. FitzGerald. Sir Jas. Haslett, Dr. Cecil Shaw, and many of the most influential men of the district were present. The lecturer gave a brief sketch of the history of electric lighting, illustrated with photographic lantern slides. He described the recent progress that had taken place in the introduction of the three-wire system and of high-tension transmission. He considered the continuous-current system would be best for Belfast, using storage batteries. He then proceeded to give a number of figures and details with reference to the proportionate cost. His conclusion was that 500 electric incandescent lamps lighted for 450 hours a year would cost £144. 17s. 6d. in a mill or works where more engineering power could be used for driving the dynamos. If the arc light could be used, as it could in the case of factories or shops having high ceilings and large space, the cost would not be more than half that amount. The cost of 500 gas lamps of equal value, basing the calculation on an expenditure of six cubic feet per hour for each lamp, and the price of gas at 2s. 7d. per 1,000ft., would be in the same amount of time—450 hours per year—£174. 7s. 6d.; and, adding £8 for incidental expenses, such as removal of burners, would bring it up to £182. 7s. 6d. Where lights were used for a shorter time, however, the case was very different, and the result came out most unfavourably for the electric light. Take 350 hours a year, for instance, in a shop or place where special power has to be supplied to drive the dynamo, and the cost would be some £220. 12s. And if the supply were taken from a central station the figures were still more startling, for taking it at 8d. per Board of Trade unit—it was contemplated, he believed, to charge 7d. in Belfast—the cost for the current alone for these lamps would be £284. 7s. 6d., and other expenses would bring the total cost up to £356. 7s. 6d., as against £220. 12s. If the consumer put in his own plant for driving the dynamo the cost of gas under similar circumstances to these last-mentioned would be only £165. 12s. 6d. He recommended private installations with gas engines when 40 lights were required for over 350 hours. After the lecture, Mr. James Perry, county surveyor for Galway, gave some account of the lighting in Galway Docks, where they used two arc lamps and some 50-c.p. incandescents. The *Galway Express* was lighted and would soon be run by electricity. Their central station cost £7,000, and costs £100 a year to run, being driven by water power and managed by two men only. Gas for lighting purposes he considered doomed. Mr. J. Milne Barbour gave an account of the use of electric light, 700 lamps, in a spinning mill, where there was a saving of 10d. per light per annum in favour of electric light.

THE ELECTROMAGNETIC THEORY OF LIGHT.*

BY JAMES H. GRAY, M.A., B.SC., PRESIDENT.

In bringing before you the subject of the electromagnetic theory of light, I propose to take up, as concisely and completely as possible in the time at my disposal, the main points in the theory, and the evidence that has been brought forward in support of it since it was first given by Maxwell 27 years ago. Of course it is only possible in this short paper to refer in the briefest manner to even the most elaborate work of some of our greatest mathematicians on this subject.

The motive which first induced the philosopher to postulate some medium which could be supposed to occupy all space, was doubtless the unsatisfactoriness of imagining such a thing as a vacuum. We find, however, that most of our students of Nature since the time of Newton have felt compelled to believe in the existence of an all pervading medium, unless they could reconcile themselves to the idea of action at a distance. Newton himself had undoubtedly a tolerably clear conception of such a medium, for he tries to explain gravitation by means of it, but, as he acknowledged, he had no experimental evidence of his theory, and so did not publish it.

It was left to the great Faraday to deal the death blow to the theory of action at a distance. To him all space in the vicinity of a source of energy was filled with lines and tubes of force. To him these lines and tubes had a real existence, just as the medium which we call ether had. He believed, as almost everyone believes now, that if energy disappears at one place and reappears after some time, it may be short, at another, it must have appeared in the interval at a succession of contiguous points between the two places. The energy must, in fact, have been propagated from the one place to the other, and the vehicle of propagation is the ether.

These splendid ideas were the foundation of the grand system which is now the groundwork of all our dynamical methods. This was the foundation of the splendid work that has since been done in this direction by several eminent mathematicians. They have taught us to look at all dynamical problems in a totally different way; for example, to look upon a wire conveying an electric current not as being wholly concerned in the conduction of the energy. They have shown that the energy is really conducted through the medium surrounding the wire, which only serves to dissipate the energy, and thus the conductor, instead of being the chief thing to be considered, is only of secondary importance. Probably the most extensive and valuable contribution to this theory of energy paths has been made by Prof. J. H. Poynting, eight years ago, in his two famous papers, "On the Transfer of Energy in the Electromagnetic Field," and "On the Connection between Electric Current and the Electric and Magnetic Inductions in the Surrounding Field." In these he not only points out that the energy may be so transmitted, but calculates out the actual energy paths. The work of Prof. Poynting, and the extensive work so powerfully done by Mr. Oliver Heaviside, did a very great deal to further the theory which, it cannot be doubted, Maxwell, but for his early death, would sooner or later have placed upon a strong theoretical and experimental basis.

At the same time, in the rush of enthusiasm with which the theory of an ether has been taken up and that of action at a distance abandoned, it is quite conceivable that we should be inclined to stretch the theory too far. The truly scientific man is almost essentially a rationalist. It seems to be engrained in his nature to try to find a reason for everything. This, no doubt, went a long way to make us give up the theory of action at a distance. It may be asked, however, if some are not pushing the idea of propagation in an ether rather too far. That one ether propagates heat, light, electrical and electromagnetic disturbances we at one time accepted without very much experimental evidence. Now we have ample evidence, but even at first we tried to explain existing phenomena by means of a theory, and did not require to invent both theory and phenomena, as, I fear, is being tried in what I am about to refer to. That the ether also propagates gravitation is very probable. Of late years, however, it has been compelled to do even more than that. In fact, according to some, we are to believe that it is the medium for propagating what are called "thought waves." Now, it would be rash to say that this is impossible, or even improbable, but it is certain that the experimental foundation of the probability of such a theory is practically *nil*. This theory of the propagation of thought waves was put forward for the purpose of explaining on scientific principles phenomena called "thought reading," "transmission of thought from one individual in one place to another in a place far removed from the possibility of direct communication," practised in its latest form by a sect called "Mahatmaists." Certainly, a scientific man, if he believed in this transmission of thought, could not, being a rationalist, attribute this phenomenon to anything spiritualistic, and he therefore must look for the reason of it. If thought transmission does exist (I have never had undisputed proof of its existence), then, certainly, such a theory does seem feasible, but the restrictions placed upon it by the believers in it—which are, in fact, that no one who does not believe in it can practise it—make it seem more or less improbable. The physical conditions necessary to cause thought-waves seem still to be most obscure.

Since energy can be transferred in different forms as energy of heat, light, electricity, magnetism, and electromagnetism, it would be necessary either to assume a separate ether for each, endowed with the suitable properties, or to endow one or more of these ethers with properties which would satisfy all these forms. Obviously if it is possible for one ether to satisfy all the conditions it would be most unscientific to assume more than one. That one ether was sufficient for heat and light had been long established, but to Clerk Maxwell it was left to demonstrate that this ether could also be made to propagate electric, magnetic, and electromagnetic disturbances. That Faraday had already conjectured this, we know, for he expressly says so, and that he found experimental proof is evident from his discovery of the rotation of the plane of polarisation by magnetic lines of force. Following after Faraday, Clerk Maxwell, in 1865, gave, as a result of his belief in the identity of the electric and optical ethers, the "electromagnetic theory of light."

Probably no more seemingly extravagant theory has ever been put forth, and had any but a great mind like Maxwell conceived it, it would most likely have been simply laughed at and passed over. As it was, it was regarded at first, and even till a few years ago, as more or less of a speculation, for, like Newton's theory, it had practically no experimental ground for its foundation.

Maxwell holds in his theory that light is an electromagnetic disturbance, and therefore the ether which propagates light also propagates electromagnetic disturbances. More strictly, the theory indicates a close connection between electric disturbances and light rather than an actual identity. Most believers in the theory now, however, feel convinced that they are actually identical, that light-vibrations are merely electromagnetic vibrations of very high frequency. We have thus an increasing frequency of vibration exhibited in electromagnetic, heat, and light-radiations.

Before going into particulars of Maxwell's theory I shall simply mention the other theories which have been devised to account for the phenomenon of light, and state the chief objections to them.

The emission, or corpuscular, need only be mentioned, as everyone knows that, whether or not the other theories be true, this one most certainly is not.

All the theories worthy of acceptance agree in two important respects—namely, that light is propagated in the form of waves, and that this propagation proceeds by means of transverse vibrations in a certain medium called the ether. The different properties attributed to this medium constitute the differences between the several theories.

The investigation of the true theory of light has occupied the minds of most of the greatest mathematicians since Newton first developed the corpuscular theory. Contemporary with Newton, Huyghens, in the end of the seventeenth century, gave, on the basis of the wave theory,

* Presidential address delivered before the Physical Society of Glasgow University.

a satisfactory explanation of reflection and refraction. His conception of the wave theory, however, was that the vibrations were longitudinal—that is, in the direction of propagation—and consequently he was unable to explain polarisation of light, a phenomenon which he himself discovered.

It remained for Fresnel to suggest that the light-vibrations were transverse, and to apply this assumption with great mathematical power to the explanation of polarisation. With Fresnel's theory, however, a number of unexplained difficulties still remained, the most notable of which was the explanation of dispersion—that is, of the different velocities of light-vibrations of different wave-lengths in the same medium. Cauchy, following Fresnel, assumed that matter was composed of molecules whose dimensions were comparable with the wave-lengths of the light-vibrations, and from this explained dispersion. He also supposed that with very long waves the velocity of propagation is independent of the period. Even with these assumptions, however, a complete explanation of the facts is not obtained. Green, discarding the "coarse-grainedness" of the ether, assumed that it was a continuous homogeneous substance, having the properties of an elastic solid, and applied the dynamics of elastic solids to the explanation of optical phenomena. According to this theory, however, there must be longitudinal as well as transverse waves. The former, therefore, we must assume, cannot affect our eyes as light, and also they must consume only a small fraction of the energy. We must assume for this purpose that the velocity of propagation of longitudinal waves is practically infinite—that is, that the ether is practically incompressible.

Besides not agreeing with experimental facts in the case of light polarised by reflection, Green's theory is in some parts quite inconsistent.

MacCullagh and Neumann, about the same time as Green, gave a theory in which they assumed that the light-vibrations were in the plane of polarisation, not perpendicular to it, as Fresnel held, and as is now pretty generally held, and the electromagnetic theory has proved. Since the velocity of propagation of transverse vibrations is given by $v = \sqrt{\frac{\epsilon}{\rho_1}}$ where v is the velocity, ϵ the modulus of elasticity, and ρ_1 the density of the ether, it will be possible to alter v either by altering both the elasticity and density, or by keeping the one constant and altering the other. Fresnel assumed that the elasticity was constant, and that the density altered with the medium. MacCullagh and Neumann, by assuming the density constant and the elasticity variable, arrived at results similar to Fresnel's.

The theories of Fresnel, Green, Cauchy, MacCullagh, and Neumann, based as they were on a pure elastic solid theory, were faulty in many ways, but have since been more or less modified and improved upon by Lord Rayleigh, Sir Geo. Stokes, Rankine, Lorenz, Kirchhoff, and others.

The theory that has been more satisfactory is one in which there is supposed to be a mutual reaction between the ether and matter. This theory has been worked out in different ways by v. Helmholtz, by Lord Kelvin in his Baltimore lectures, Sellmeier, Lommel, Ketteler, and Voigt. It would take up too much space here to consider even most summarily the several points in all the different theories, and it is, besides, unnecessary, for a detailed account and discussion of them can be found in Glazebrook's admirable "Report on Optical Theories," in the British Association Report for 1885. It must suffice here to state that neither the theories based solely on the dynamics of the ether considered as an elastic solid, nor theories in which the ether and matter are supposed to mutually react on each other, have been found sufficient to overcome all the difficulties surrounding optical phenomena. One of the most important difficulties that the elastic solid theories cannot get over is the want of indication of a longitudinal wave which the theories demand, unless the ether be incompressible. Also the phenomena of reflection can be explained most easily by assuming that the vibrations are perpendicular to the plane of polarisation, while the phenomenon of double refraction can be most easily explained by assuming that the vibrations are in that plane. The phenomena of double refraction also demand a most elaborate connection between the coefficients of elasticity of the ether. On the other hand, as Maxwell says in his splendid article on "Ether," in the ninth edition of the "Encyclopædia Brittannica": "The electromagnetic theory of light satisfies all these requirements by the single hypothesis that the electrical displacement is perpendicular to the plane of polarisation. No normal displacement can exist, and in doubly refracting crystals the specific inductive capacity for each principal axis is assumed to be equal to the square of the index of refraction of a ray perpendicular to that axis."

That the electromagnetic theory is a completely satisfactory theory is unfortunately not yet established, but it is the theory which has fewest assumptions and explains most. Indeed, all the phenomena that can be explained by the other theories can be as well explained by the electromagnetic theory, and, besides these, a number of objections to the other theories are avoided. The peculiar disadvantage of the theory, however, is the difficulty of realising clearly what electrical polarisation—or, as Maxwell calls it, electric displacement—is. Before mentioning what has been done in this direction, I shall take up that part of the theory which was first developed.

In 1865 Maxwell gave his theory, the substance of which is contained in the second volume of his "Electricity and Magnetism," Chapter 20. In Chapter 9, on the "General Equations of the Electromagnetic Field," he brings into prominence what he calls "displacement" currents. In a medium capable of conducting a current, he supposes the whole current to be represented by the sum of the ordinary conduction current and the displacement current. The explanation of the latter will be best made in Maxwell's own words: "When the E.M.F. acts on a conducting medium it produces a current through it, but if the medium is a non-conductor, or a dielectric, the current cannot {continue to} (the words in brackets are Prof. J. J. Thomson's) flow through the medium, but the electricity is displaced within the medium in the direction of the electromotive intensity." The rate of this displacement is, therefore, the current.

As, in Chapter 20, his chief object is to obtain the equations for the electromagnetic disturbance in media which are capable of transmitting light, he first takes the case of a perfect non-conductor, as his theory indicates that a good conductor of electricity is opaque, and a good insulator transparent to light-vibrations. He then gets three differential equations for the determination of the E.M.F.'s F, G, H along the three axes of co-ordinates,

$$K\mu\frac{d^2 F}{d t^2} = \frac{d^2 F}{d x^2} + \frac{d^2 F}{d y^2} + \frac{d^2 F}{d z^2},$$

and similar equations for G and H, where K = specific inductive capacity, and μ = the magnetic permeability of the substance. Now, these equations are precisely similar to those for irrotational motion in a homogeneous aeolotropic elastic solid. The equations for this case are—

$$\rho_1\frac{d^2 u}{d t^2} = M\left(\frac{d^2 u}{d x^2} + \frac{d^2 u}{d y^2} + \frac{d^2 u}{d z^2}\right)$$

etc., etc., for v and w, the displacements along the other two axes, where ρ_1 is the density and M the elasticity of the solid.

We see, therefore, that $\frac{M}{\rho_1}$ in the elastic solid corresponds to $\frac{1}{K\mu}$ in the electric problem. $\frac{M}{\rho_1}$ is the length-modulus, so $\frac{1}{K\mu}$ is proportional to the length-modulus of the ether. As a matter of fact, we have for the total displacement or strain across any closed surface $D = \frac{Q}{4\pi r^2}$, and for the force producing this displacement, $F = \frac{Q}{K r^2}$, where Q is the quantity of electricity on the surface. We have thus, from analogy,

$$\text{Electric elasticity} = \frac{\text{stress}}{\text{strain}} = \frac{F}{D} = \frac{\frac{Q}{K r^2}}{\frac{Q}{4\pi r^2}} = \frac{4\pi}{K}$$

We see, then, that $\frac{4\pi}{K}$ corresponds to M, and $\frac{1}{K\mu}$ corresponds to $\frac{M}{\rho_1}$, and we have, therefore, that $4\pi\mu$ is the electromagnetic density of the medium, and $\frac{4\pi}{K}$ the electric elasticity. So far, then, the electromagnetic disturbances have been treated in exactly the same way as if electromotive force were proportional to displacements in a homogeneous elastic solid, whose density is $4\pi\mu$, and elasticity $\frac{4\pi}{K}$. Now, μ and K both vary with the medium, and therefore the electromagnetic theory so far agrees with a simple elastic solid theory, in which not only the elasticity, as Fresnel assumed, and not only the density, as MacCullagh and Neumann assumed, but both quantities vary. As regards dielectrics, therefore, we might so far consider, on the electromagnetic theory, that electrical and light disturbances in them are simply displacements in the ether of the dielectric, this ether having its elasticity equal to $\frac{4\pi}{K}$ and its density equal to $4\pi\mu$. This would then give for the velocity of propagation of both disturbances $\frac{1}{\sqrt{K\mu}}$. This gives us at once the first test of the theory, since we know that light of all wavelengths travels with the same velocity in vacuum or air, for which K is unity and $\mu = \frac{1}{v^2}$ on the electrostatic system of measurement, and $K = \frac{1}{v^2}$, $\mu = 1$ on the electromagnetic system, v being the number of electrostatic units of electricity in an electromagnetic unit. It is therefore necessary that v should be rigorously equal to the velocity of light in vacuum. We find a very close though not perfect agreement, the velocity of light as last measured by Newcomb being $2{\cdot}99766 \times 10^{10}$ centimetres per second, while the value for v found by J. J. Thomson two years ago was $2{\cdot}9955 \times 10^{10}$. This small difference is quite within the range of experimental error.

(To be continued.)

THE COST OF ELECTRIC SUPPLY.*

BY DR. JOHN HOPKINSON, F.R.S.

The interests of an engineer are many sided. If he is to successfully use the forces of Nature for the service of man he must understand how those forces work; he must, in fact, be scientific. It may be that his ideas are arranged differently from the ideas of those who study science for its own sake, and without regard to practical applications, but if he is to succeed they must be so arranged that he can deduce from knowledge already acquired, knowledge which is applicable to new cases which have not as yet come under his observation. The engineer who can only do that which he has seen done before may be a practical man, but he will always belong to a lower grade of his profession. The scientific engineer is one who by his knowledge of Nature is able to deal with new engineering problems and provide useful solutions of those problems. But a practical man must be something more than a man of science, or rather he must look at matters from a different point of view. He cannot choose some feature of a problem, concentrate all his attention upon that, and leave other matters out of consideration, which is the process by which most scientific advance has been made; but he must always deal with the whole matter before him and leave no relevant question out. But an engineer may be scientific, inasmuch as he has knowledge of Nature and the power of applying that knowledge in new cases; he may be practical in the sense that the means he devises to attain his ends may be complete at all points, and not break down from trifling defects, and yet may find that there are other subjects which he has to consider. Our complete engineer must give his attention to commercial matters as well; he must know if, when he has devised the means to attain the ends in view, those ends when attained will result in profit. He must recognise the conditions which render an undertaking economical to work, and which secure that it shall bring in a large return. When it has been my lot to address engineers I have usually directed attention to some scientific point which I thought would be of interest to them. This evening I should like to go to the other extreme and deal with a purely commercial question, with a matter into which no science enters, and which relates entirely to pounds, shillings, and pence.

You are all of you familiar with the fact that the expenses of an undertaking may be broadly divided into two classes. On the one hand there are expenses which are quite independent of the extent to which the undertaking is used, and on the other, expenses which are absent unless the undertaking is used and which increase in proportion to the use. For example, the charges for interest on the construction of a bridge are the same whether that bridge is used much or little or at all, and the cost of maintaining the bridge is also practically independent of its user. The same is true in a large measure of a harbour or a dock. Such undertakings lie at one extreme of the scale. It is less easy to find good examples at the present day of the other extreme, as nearly all undertakings with which engineers have to deal require the employment of some capital, and there will be a fixed charge for the use of that capital, and for maintaining against the assaults of time the things in which the capital is embodied. But we can readily see, for example, in the case of a cotton mill, that if, on the one hand, there are expenses for interest and dilapidation which are independent of the amount of yarn actually manufactured in a given factory, there are other expenses for material and labour, and even for actual wear of machinery, which will be very nearly proportional to the output. Undertakings vary enormously in the proportion of these two classes of expenses, in some the expense is quite independent of the extent of the user, in others it is for the greater part proportional to the user.

But undertakings differ from each other in another respect. In some cases the service which the undertaking is designed to render can be performed at a time selected by the undertakers; in others, at a time selected by those to whom the service is rendered. In the case of most manufactures, it matters not if the thing made is made to-day or to-morrow, in the morning or the evening, for it will not be used for a month hence, perhaps. The thing can in fact, be extensively stored and kept till it is wanted. Other services must be rendered at the moment the person served desires. For example, the Metropolitan District Railway must be prepared to bring in its thousands of passengers to the City at the beginning of the day and to take them back in the evening, and for the rest of the day it must be content to be comparatively idle. In this case the service cannot be stored. The line must be of a carrying capacity equal to the greatest demand, and if this be great for a very short time the total return for the day must be small in comparison with the expense of rendering the service. In such a case it would not be inappropriate to charge more for carrying a person in the busy time than in the slack time, for it really costs more to carry him.

Let us see how these considerations apply to the supply of electricity for lighting. Electrical engineers now realise that they have to provide the same plant and no more to give a steady supply day and night as to give a supply for one hour out of the 24. They also now realise that if they are to be ready to give a supply at any moment, they must burn much coal and pay much wages for however short a time the supply is actually taken. Indeed, the term "load factor" proposed by Mr. Crompton is as constantly in the mouths of those who are interested in the supply of electricity, as volt or ampere or horse-power. The importance of the time during which a supply of electricity is used was so strongly impressed on my mind years ago, that in 1883 I had introduced into the provisional orders with which I had to do a special method of charge intended to

* Presidential address delivered before the Junior Engineering Society, Nov. 4, 1892.

secure some approach to proportionality of charge to cost of supply. Unfortunately, the orders of that day all came to nought.

A supply of electricity must be delivered at the very moment when the consumer chooses to use it, and as long as and no longer than he pleases to use it; it cannot be very readily or cheaply stored, and much of the cost of production is the fixed charge for plant and conductors. Furthermore, the provisional orders require that the supply shall be available at all hours; hence coal must be consumed and workmen must attend, though but few consumers are drawing a supply. The service of supplying electricity has from an economic point of view a great deal of similarity to the service of providing a breakwater for a harbour. A great deal of the expense is independent of the number of hours in the day during which the supply is used. To put it in another way, the cost of supplying electricity for 1,000 lamps for 10 hours is very much less than 10 times the cost of supplying the same 1,000 lamps for one hour, particularly if it is incumbent on the undertaker to be ready with a supply at any moment that it is required.

The actual importance of considerations of this kind can only be realised by examining figures. The figures may as well be estimated figures, because the circumstances vary from one neighbourhood to another. No criticism of the details of the figures will affect the general character of the conclusion. Let us then imagine a station capable of supplying 40,000 16-c.p. lamps at one time, with mains and spare machinery enough to ensure that the supply shall not fail, and let us see what the charge for running such a station will be: firstly, on the hypothesis that it is always to be ready to supply the 40,000 lights at half-an-hour's notice day or night but that the lights are hardly ever actually required; secondly, on the hypothesis that the 40,000 lights are steadily and continuously supplied day and night. These are the two extreme cases possible. In the former the load factor is nil; in the latter it is 100 per cent. If the charge is by meter at 8d. per unit in the former case, the revenue will be nil; in the latter it will be £730,000 a year.

We are going to divide the cost of supplying electricity into two parts: a part which is independent of the hours the supply is used, and a part which is directly proportional thereto, and we are going to estimate the amount of each element. It is for the purpose of ascertaining these elements that we consider two quite hypothetical cases, cases which can themselves never actually occur.

We must first have an idea of the capital outlay required. To provide the maximum of 40,000 lamps we need to deliver 2,500 units per hour, and we may estimate the capital outlay as follows:

Land	£25,000
Buildings	15,000
Boilers and pipes	14,000
Engines	24,000
Dynamos	15,000
Switchboard and instruments	2,000
Feeders and mains	50,000
	£145,000

Let us deal with the annual charge for each item of capital separately on the two hypotheses. The charge for land and for buildings, including repairs, is clearly the same in the two cases—say, at 4 per cent., £1,000 for the land, and at 10 per cent., £1,500 for the buildings. The boilers, engines, and dynamos will have a charge for interest, and a charge for writing off—or amortisation as the French call it—that is, for writing off the value of the plant before the time at which it becomes antiquated—exactly the same in the two cases. The boilers, too, will require exactly the same repairs whether they are merely keeping steam or whether they are generating steam continuously; but the machinery will certainly require more for repairs and renewals if it is all running than if a part only is running without load and the rest is standing ready for a load if required. I take 4 per cent. as the charge for interest, 3 per cent. for amortisation, 8 per cent. for repairs and maintenance. Of the repairs of engines and dynamos I assume that 2 per cent. will be applicable if the plant runs light, the remaining 6 per cent. if it is fully and continuously loaded. The expenses connected with conductors and switchboard, etc., will be exactly the same whether the current is passing or not; these I take at 15 per cent. The rates I put down at £500 a year. The account, then, for the fixed charges already enumerated would stand as follows:

	Running light.	Fully loaded.
Land	£1,000	£1,000
Buildings	1,500	1,500
Rates	500	500
Boilers	2,100	2,100
Switchboard and conductors	7,800	7,800
Engines	2,160	3,600
Dynamos	1,350	2,250
	£16,410	£18,750

We now come to a most important item in the account, the coal. There is no doubt that with uniform and continuous load a unit of electric energy—1⅓ h.p. for one hour—can be produced for less than 3lb. of coal; it is also pretty much admitted that with a load factor of about 12 per cent., but continuous maintenance of pressure, the consumption of coal in good practice is something like 7lb. That is to say, to keep the boilers warm, turn round the machinery for 24 hours, and deliver full current for 24 hours, will require 72lb. of coal per kilowatt; whereas, to keep the boilers warm, turn round the machinery and deliver current for three hours, will require 21lb. of coal. The boilers being kept warm, it will take 51lb. of coal to generate steam enough to give a unit per hour for 21 hours; 58lb. to give a unit per hour for 24 hours; subtracting this from 72lb., the amount required both to generate steam and keep the boiler warm, we may infer that to keep the boiler warm and merely turn the machinery in readiness to meet a demand will take about 14lb. of coal per day for every unit per hour the plant is capable of producing. In 1889, for the Society of Arts, tests were made of a Paxman compound engine, from which it appears that a boiler which when fully loaded consumed 40lb. of coal per hour, required 4lb. per hour to keep steam up to normal pressure when the engine was standing—that is, 10 per cent. of the coal used was used to maintain the steam pressure. Remembering that in addition we keep some of our machinery moving, this may be said to confirm the figures adopted. Thus, if the plant runs light all the year round, 12,775,000lb., or let us say 6,000 tons, of coal will be consumed. If the plant runs fully loaded 65,700,000lb., or let us say 30,000 tons, will be consumed. If we suppose the coal to be best smokeless it might cost 20s. per ton. Next we have water, oil, and petty stores—say, £600 and £3,000 in the two cases. Wages will be a little less if we run light than if we run fully loaded, and of course will largely depend on local circumstances; let us say £5,000 and £7,500 in the two cases. This gives us substantially all the expenses which have to be met, and our account will then stand thus:

	Running light.	Fully loaded.
Fixed charges	£16,410	£18,750
Coal	6,000	30,000
Stores	600	3,000
Wages	5,000	7,500
	£28,010	£59,250

Thus the cost of merely being ready to supply 2,500 units per hour at any moment throughout the year will be £28,010, and the cost of actually supplying 2,500 units per hour for every minute in the year will be £59,250. The undertaker therefore who incurs the liability to supply ought to receive £11 per annum per unit per hour from those on whose behalf he incurs the liability, and if he receives the £11 he need not charge more than ⅓d. per unit for what he actually supplies, to cover his expenses. That these figures are fair approximations can be seen as follows: According to this calculation the cost of supplying 2,500 units for one hour per day is £28,010 + 2,500 × 365 × ⅓d. = £29,277, and the charge for the service at 8d. a unit would be £30,410; it is doubtful if such a supply would pay. On the other hand, an indicated horse-power on such a scale could certainly be supplied continuously for from £12 to £14 per annum, and, according to this calculation, an electrical horse-power will cost just £18 per annum. No account is taken of expenses peculiar to companies, such as

directors' fees and the cost of forming the company. It will also be noted that it is assumed that accumulators are not used.

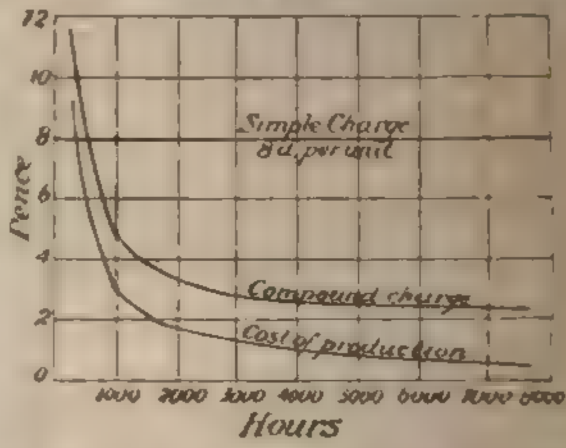
The charge for a service rendered should bear some relation to the cost of rendering it. If it is a matter of open competition the matter will settle itself, for no one will be long be able to supply some customers at a loss, and recoup himself by exorbitant profits from others. If the matter be a case more or less of monopoly, the adjustment is less certain, thus the Post Office charges ½d postage for a printed circular and 1d for a written letter, the two costing the Post Office exactly the same. What a boon to the public it would be if the Post Office would charge more for printed trade circulars, which in nine cases out of ten are a nuisance to those who receive them. The supply of electricity is not quite a monopoly; companies compete with each other, and there is always the competition with other methods of illumination, such as gas and paraffin. It is clearly to the advantage of the undertaker to secure all those customers whom it pays best to supply, and as far as may be to compel those who are unremunerative to adopt these other methods. The ideal method of charge, then, is a fixed charge per quarter proportioned to the greatest rate of supply the consumer will ever take, and a charge by meter for the actual consumption. Such a method I urged in 1883, and obtained the introduction into certain provisional orders of a clause sanctioning "a charge which is calculated partly by the quantity of energy contained in the supply and partly by a yearly or other rental depending upon the maximum strength of the current required to be supplied." In fixing the rates of fixed charge it must not be forgotten that it is improbable that all consumers will demand the maximum supply at the same moment, and consequently the fixed charge named might be reduced or some profit be obtained from it. There is no object in reducing the cost of electricity for lighting in the case of any customer much below the cost of equivalent lighting by gas, unless there are competitors in the field willing to do it, hence the current charge proportioned to the power supplied may safely be increased. In certain recent cases in which I am acting as engineer, the Board of Trade have sanctioned on my application, "for each unit per hour in the maximum power demanded, a charge not exceeding £3 per quarter, and in addition for each unit supplied a charge not exceeding twopence." It is sometimes said, as an objection to this method of charge, the public will object to pay a fixed charge whether they make use of their lights or not, and that, in fact, they will not pay it. The best answer that can be made is to give everyone the choice of being charged the maximum simple rate provided by the order, or by the compound rate as they prefer. What is wanted is not so much an increased charge for those consumers whose lights are used for a short time, as such a special reduced charge for those whose lights are used long as will induce them to use the supply.

It is instructive to compare the cost to different classes of consumers of electricity and gas for lighting with 16-candle gas. Flat flame burners must be large and of first-rate quality to give more than two candles per cubic foot of gas per hour; the large majority of burners give much less than this even at their best, and as a rule the pressure of the gas is not regulated and much gas is wasted as far as the production of light is concerned. Incandescent lamps give about one quarter of a candle per watt; hence a B.T.U. is equivalent to 125 cubic feet of gas. Thus we readily arrive at the following comparative table, the charge being at the rates recently sanctioned by the Board of Trade:

Hours of use per annum.	Load factor.	Price of gas at which cost of lighting by electricity and 16-candle gas are equal
480	5.5	5s. 4d
960	10.9	3s. 4d
1,440	16.4	2s. 9d.
1,920	21.9	2s. 4d.
2,880	32.9	2s. 0d
3,840	43.8	1s. 10d
7,680	87.6	1s. 7d.

In the accompanying curves are shown the cost of production, and the charge per unit at the compound and simple rate. The ordinates represent pence and the abscissæ the number of hours per annum the supply is used.

It is obvious that those whose user is long will find the electric light economical to themselves and that it will be profitable to the undertaker. With a cheap light which is free from the products of combustion there will be extensions for the hours of use. Shops may find it worth while to continue the light after closing, as an advertisement.



We have so far assumed that the supply of electricity is carried on without the aid of accumulators. Let us first compare the cost of an electric accumulator with the cost of a gasholder containing the same possibility of producing light. A gasholder is at present being put up in Manchester to hold 7,000,000 cubic feet of gas, and is to cost complete with its tank £60,000. With 16-candle gas 7,000,000 cubic feet are equivalent to 56,000 B.T.U. Accumulators capable of storing a 10-hours' supply, cost about £50 per unit. The equivalent accumulator will therefore cost about £280,000. But this is not all; the gasholder is comparatively permanent; the accumulators require frequent renewals and repairs; the gasholder gives back all the energy put into it; the accumulators waste at least 20 per cent.; the gasholder may be emptied as fast as you please, the accumulators, not faster than a certain rate without diminishing their capacity. Taking all into consideration, the cost of storing energy by the use of accumulators, and storing it in a gasholder, are quantities of a different order of magnitude. If no gasholders were used, and all the gas had to be made just as it was wanted, its cost for lighting would be several fold what it now is, even if gas producers could be found capable of instantly varying the supply as the demand varies. The gas producing plant would have to be enormously increased, so would the size of the mains, and so would the wages of labour. If electric power could be stored as cheaply as gas, there would soon be little hope that the gas companies would maintain their dividends.

Let us see from a financial point of view whether accumulators can be used economically for storing up electrical power continuously produced during the 24 hours, and used rapidly for a short time.

Assume that the whole of the plant with the accumulators is capable of supplying 40,000 lights for 10 hours continuously, and that during that time half the power is supplied from the accumulators. Ten hours in the 24 hours is not an unreasonable allowance, for we have melancholy experience in London of continuous fog for days, and this would tax the plant we are considering to the utmost. We are to be ready then at any time on short notice to supply 40,000 lights, and to continue to supply them for 10 hours. Compare the cost, firstly of maintaining this state of readiness with the accumulators and with a plant without accumulators. We shall require a battery capable of giving 1,250 units for 10 hours; such a battery costs not less than £50 per unit, or in all £62,500. To maintain it, will cost from 10 to 15 per cent. on the cost; there will also be interest on the outlay and amortisation—say, in all 20 per cent., or £12,500 a year. If we assume that the batteries are distributed at the various points of the system of conductors, we may also assume that the charges for land and buildings will be much the same as for the plant without accumulators. The

boilers, engines, and dynamos will be just one-half. The switchboard and instruments will be much the same. But the conductors will be reduced, smaller or shorter feeders being necessary, probably £40,000 will go as far with accumulators as £50,000 without. The coal bill may be dispensed with entirely, as we may assume that steam could always be got up during the time in which the demand increased from nothing to one-half of the maximum, and that therefore all the coal burned can be assumed to be burned for producing current. That is to say, we assume the quantity of coal burned is proportional to the quantity of electric energy, and that therefore when no electricity is actually used no coal will be burned. The wages may be reduced, for we have only to be ready to run half the plant, and a small wage will suffice for attendance on the accumulators. The wages of linesmen and the like will remain the same. Assume the total wages to be £3,500 instead of £5,000. The account will then stand thus:

Land	£1,000
Buildings	1,500
Rates	500
Accumulators	12,500
Boilers	1,050
Engines	1,080
Dynamos	675
Switchboard	300
Conductors	6,000
Wages	3,500
	£28,105

practically the same result as we obtained before.

Now, consider another hypothetical case, which, of course, can never occur in practice. We are to supply 40,000 lamps for 10 hours every day with the plant just described, charging the accumulators during 12½ of the 14 hours during which the light is not required, 12½ hours charging giving 10 hours discharge of the same energy. The coal would cost the half of £30,000 if the machinery had to run the whole of the 24 hours. It has to run 22½ hours, but the boilers have to be kept warm the whole time, hence the coal will cost the half of £6,000 for keeping the boilers warm, and $\frac{22\frac{1}{2}}{24}$ of the half of £24,000 for generating steam. The wages may fairly be taken as £4,750, and the account will stand:

Land	£1,000
Buildings	1,500
Rates	500
Accumulators	12,500
Boilers	1,050
Engines	1,800
Dynamos	1,125
Switchboard	300
Conductors	6,000
Wages	4,750
Coal	14,250
Stores	1,425
	£46,200

The cost of supply for the same 10 hours without accumulators would be as follows:

Land	£1,000
Buildings	1,500
Rates	500
Boilers	2,100
Switchboard and conductors	7,800
Engines	2,760
Dynamos	1,725
Coal	16,000
Stores	1,600
Wages	6,000
	£40,985

a cost of about 11 per cent. less than where accumulators are used.

Putting it another way, the cost of being ready to supply and to continue to supply is about the same whether accumulators are used or not; the additional cost of actually supplying current is about 40 per cent. more where accumulators are used than where they are not used. It may be safely inferred that the use of accumulators does not seriously alter the conclusions I have drawn as to the proper method of charging consumers for a supply of electricity.

The question of whether the great cost of a supply for short hours can be removed by the use of accumulators may be looked at in another way. Will it pay a consumer to put in his own accumulators and charge them from the station supply? We may reasonably suppose the undertaker will remit the fixed charge in consideration of the consumer only taking his current at slack times. His accumulators, if they are to be of capacity to maintain his supply through a foggy day, will cost him £50 per unit per hour (or per kilowatt), and the annual charge in respect of them will be £10 per year, to which, if we add a rent for the space the battery occupies, gives us a charge not differing materially from the fixed charge made, or suitable to be made, by the undertaker. But in order to obtain 2d. worth of electricity he must purchase 2½d. worth for charging his battery.

A word or two more about the use of accumulators. These have certainly improved, and they will continue to improve. They will become more durable and more economical of power in working, and their first cost will become less. An inspection of my tables of cost shows that a very little improvement would render them valuable even in very large stations for the mere purpose of diminishing the machinery required, by storing the energy developed at slack times to be used in busy times. The certainty of improvements in accumulators, and the possibility that the improvement may be considerable, is a strong argument for the use of the direct current wherever it is not precluded by the distance of transmission being too great. It will be noted that I have assumed a very large station. Accumulators have another use which greatly increases their advantage in smaller stations. There are many hours in the 24 when it is absolutely certain that the demand will be small. If accumulators are used the attendance of the staff may be dispensed with during those hours, and a considerable sum in wages will be saved. The proportion of wages to the whole of the charges is much greater in small stations than in large. In most small stations giving continuous supply accumulators ought to be used, notwithstanding their expenses and defects, and I believe the day is not far distant when they ought to be used in connection with most large stations also.

If, instead of a continuous current, an alternating current with transformers is used, the modification in the account will be that the cost of conductors will be diminished, but the cost of transformers will have to be added. If the distances are small, the increased cost of transformers will exceed the saving in the conductors; if the distances are considerable, the cost of transformers will be less than the saving of conductors. In both cases the general character of the result will be the same as before, the cost of being prepared to give a supply will be considerable, and the cost of actually giving the supply will be much smaller than is generally supposed. Indeed, with the alternating current this peculiarity will be even more marked, for the machinery has not only to be kept in motion, however small the consumption may be, but a certain current must be maintained in every transformer. With the best transformers this current may only have an energy 1½ per cent. of the energy of the current when the transformer is fully loaded. This would increase the coal bill in the case considered by about £500 per year whether the supply was used or not.

It is possible, indeed probable, that some of my assumed figures may be shown to be too high or too low for the generality of cases. It is of no moment; let each one take any figures he pleases within reason; let him assume that the supply of electricity is made by any system he pleases; he will arrive at a result broadly similar to mine. To be ready to supply a customer with electricity at any moment he wants it will cost those giving the supply not much less than £11 per annum for every kilowatt—that is, for every unit per hour—which the customer can take, if he wishes, and afterwards to actually give the supply, will not cost very much more than ½d. per unit. This is the point I have been labouring to impress, for I take it is essential to the commercial success of electric supply. It is hopeless for electricity to compete with gas in this country all along the line, if price is the only consideration. But with selected customers, electricity is cheaper than gas. Surely it is the interest of those who supply electricity to secure such customers by charging them a rate having some sort of relation to the cost of supplying them.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations ; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 months
United Kingdom . . .	3s. 3d. ..	6s. 6d. .	13s. 0d.
Other Places	4s. 11d.	9s. 9d. .	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. IX. of new series of "THE ELECTRICAL ENGINEER" *can be had, bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

COMPANIES' FINANCIAL STATISTICS.

In another column we give some financial statistics, compiled by Messrs. Faithful Begg and Co., relating to electrical companies. This compilation covers but a small field, and leaves out a large number of companies, but from many points of view it is interesting. It may, however, be taken as including most of the companies whose shares have a market, and are bought and sold on the Stock Exchange. Comparisons are odious, yet we are fain to point out that from October, 1878, when the "British Electric" was promoted, to the end of 1882, some fifty-six companies were floated with a total capital of £20,910,500. Of course the whole of this capital was never paid up, but the greater half was, and the major portion of the capital so paid up was entirely lost. During that palmy time for promoters, investors lost their heads, and their money. Of the above-mentioned fifty-six companies no less than twenty-four saw the light in one month—viz., May, 1882; in fact, all but five saw the light in that year. Now we are drawing towards the close of 1892, and this list of Messrs. Begg and Co. comes to remind us of successes and of failures. Dividing the companies into two classes, as in the tabular statement, the supply companies mentioned have a total capital of close on five and a quarter millions, of which just over two millions eight hundred thousand pounds are paid up. The total profit during the year, so far as the figures are available, amounted to a little over twenty-five thousand pounds, or not quite one per cent. on the capital paid up. The manufacturing companies show a much better return than this, though we may here call attention to one remarkable omission on the part of the compiler. Where is "Woodhouse and Rawson"? It is neither among the supply nor the manufacturing list. However, the list as given shows a total capital of close on four and three-quarter millions, and a called-up capital of close on two million seven hundred thousand. The profit during the year reached the satisfactory figure of two hundred and eleven thousand, or nearly eight per cent. upon the paid-up capital.

At the present moment, then, there is a broad distinction between the earning powers of the supply and the earning powers of manufacturing companies, and the question naturally arises, Is this a detriment to the supply companies? In our opinion it is not, and our reason for touching upon these financial statistics is to explain why it is not; otherwise investors might feel inclined to button up their pockets, and great damage might accrue to the industry by a mere circulation of figures without the facts of the case being clearly put. It must always be remembered that supply companies have to legislate for the future rather than for the present. A large portion of their capital expenditure, therefore, is understood to be for the moment unproductive, but differing from the manufacturing concern their income should be a rapidly-increasing one, and not till they have full load upon their mains and stations will the capital expended bring in its full return. In the manufacturing concern the expenditure is more or less proportional

to the receipts, and as the business increases the expenditure proportionally increases, but the opposite is the case with the supply companies—the initial expenditure being out of all proportion to the returns. We should imagine, also, that the profits from the manufacturing concerns have even now about reached their limits, and that the shareholders do not expect much, if any, more. The difference may be put in another way. With manufacturing concerns the maximum return upon capital is quickly reached; with the supply companies the maximum comes slowly, but when obtained is more likely to be constant. It is not liable to competition derangement. Manufacturers compete one against the other for orders, and the tendency is always to knock down prices in order to get work. Little or nothing of the kind happens with supply companies, and as lamps are gradually added the income increases more rapidly than the expenditure. These views should be made as widely known as possible when the public is deluged with statistics of the kind we have referred to. We will go so far as to venture to assert that even the London Electric, with its huge capital and its shares at present merely of nominal value, may turn out a lucrative investment to those who come in now, providing the management is conducted properly. Only a portion of its capital is irretrievably lost—that which has been spent upon engines and dynamos which will never be erected, and which if erected would lead to loss instead of profit. If the company goes on carefully it may add, from revenue, unit to unit, till the full capacity of the station is reached with workable units rather than with exceptional units. The statistics, so far as we are concerned, may now be studied by every reader with considerable advantage.

OBITUARY.

THE LATE DUKE OF MARLBOROUGH.

We regret to have to record that on Wednesday the Duke of Marlborough was found dead in his bed. It seems that his valet, as was usual, went into his room with some cocoa, and at first saw nothing amiss. Subsequently on opening the blinds he found the Duke was dead, and immediately gave the alarm. According to all information death seems to have been caused by syncope. The late Duke of Marlborough was the eighth, and was born in 1844. Of late years he has been closely allied to the electrical industry. He was chairman of the New Telephone Company, the Brush Electrical Engineering Company, and the Electric and General Investment Company, and a director of the City of London Electric Lighting Company. It will be remembered that he took a very active part in the formation of the New Telephone Company and the amalgamation with the National; in fact, during the last two or three years, he has been one of the most active spirits in the development of electrical enterprises connected with lighting and telephonic matters.

THE LATE MR. EDWARD GRAVES.

It is our painful duty to record the death of Mr. Edward Graves, engineer-in-chief to the British Post Office Telegraphs, which occurred in the early morning of November 9th, 1892, caused by diabetes, from which he had suffered for some time.

Mr. E. Graves was born in February, 1834, and after a brief connection with the North-Eastern Railway Company, he first became connected with telegraphy in 1852, when he entered the service of the Electric and International Telegraph Company at York, under Mr. de Chesnel, whom he acted for during a prolonged illness, and in 1856 succeeded as superintendent and district engineer for the East Coast of England and Scotland, extending from London to Aberdeen. As the company's system developed the district was divided, and at the transfer of the telegraphs to the State in 1870, Mr. Graves was divisional engineer for the Northern district, with headquarters at York. Possessed of great administrative ability and financial acumen his interests were employed in defending the interests of the Post Office during the arbitrations, 1874-8, between the department and the various railway companies who were entitled to compensation under the Telegraphs Act of 1868, and the success of his efforts was mentioned by Sir Richard Bagallay, then Attorney-General, and other eminent counsel connected with the cases, and received official recognition by the department. In 1878, Mr. R. S. Culley, the engineer-in-chief, retired from active service, and Mr. Graves was appointed to succeed him in that office, and immediately reorganised the engineering staff. He was a delegate to the Paris Electrical Conference in 1881, and received the cross of an officer of the Legion of Honour from the French Government; he was a member of the Channel Tunnel Defence Committee, in 1882; of the Electrical Standard Units Committee; and of the Royal Commission on Electrical Communications with Lighthouses and Lightships, whose report is expected shortly. Mr. Graves was one of the early members of the now Institution of Electrical Engineers, of which he was for many years honorary treasurer, and in 1888 was its president.

ELECTRIC LIGHTING OF SMITHFIELD MARKETS.

On Friday evening last week the then Lady Mayoress, accompanied by the then Lord Mayor and a distinguished party of City magnates, performed the ceremony of switching on the electric light to these markets. In our last issue we described the temporary installation and the proposed permanent installation, but we venture to predict that the permanent installation will eventually be even larger than we described. The inaugural ceremony took place in the poultry and provision section of the Central Markets, which completes the series of markets erected by the Corporation. The Lord Mayor and the Lady Mayoress were received on their arrival by Mr. H. W. Greenwood (chairman of the Grand Markets Committee) and the members thereof, and were conducted to a platform, the Lady Mayoress being presented by Mrs. Sax with a handsome bouquet. Mr. Greenwood addressed his lordship, and invited him to inaugurate the important addition to the markets which had just been completed by Messrs Sax and Co., the contractors, whom he introduced. The markets, he said, had now been completed, at a total expense to the Corporation of £3,300,000, and an evidence of the ever-continuing importance of the buildings was to be found in the fact that the weight of goods delivered in the present year had been 8,332 tons in excess of that for the corresponding period of last year. The length of the wire required to complete the installation was about 40 miles, while the number of incandescent lamps to be fitted on the premises of tenants reached 12,000, of from 15 c.p. to 50 c.p. each. The main avenues would be lighted with 100 lamps of 50 c.p. each. The plant consisted of six dynamos with an output of 200 units each, worked by four engines of 200 h.p., two additional engines being held in reserve to provide against any chance of failure. The whole of the instruments used in the installation had been manufactured by Messrs. Sax, at their own factory, and the entire work formed the largest private incandescent scheme yet undertaken. The Lady Mayoress, upon the invitation of Mrs. Charles Sax, then removed a jewelled dagger placed in a piece of mechanism on the platform, and the electric light at once flooded the markets, loud cheers greeting its appearance. Mrs. Sax presented her ladyship with the dagger, which was much admired. A vote of thanks to the Lord Mayor and the Lady Mayoress, moved by Mr. George Taylor, chairman of the Central Markets Committee, concluded the proceedings.

Subsequently about 100 guests met, at the invitation of

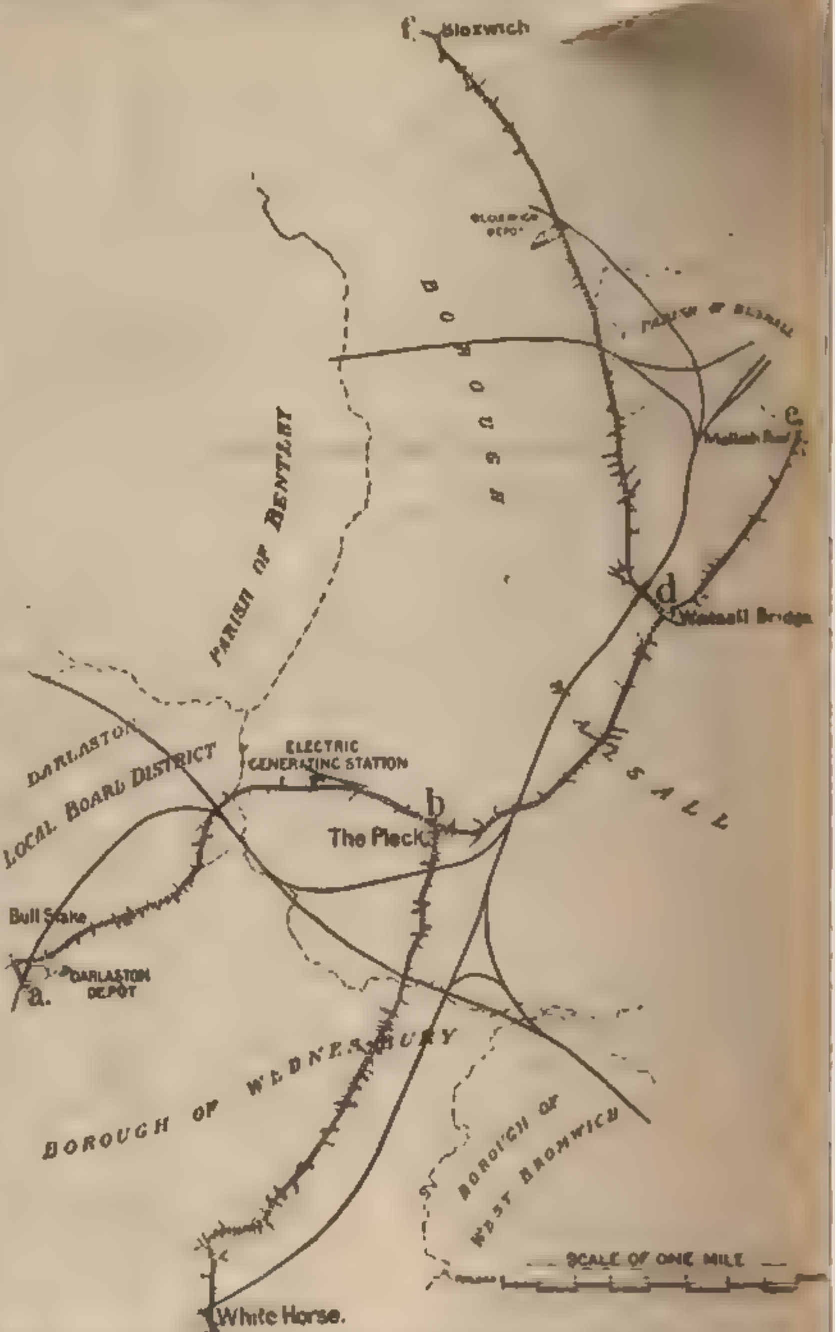
Messrs Sax, the contractors, to dine at The Dr Butler's Head, Mason's yard. The dinner was all that could be desired, and it was perfectly evident from the various speeches that a keen desire exists in the City for the success of electric lighting.

When the permanent installation is complete we hope to have more to say on the subject. Meanwhile the wiring and other arrangements are being carried out with great care and energy, so that there is every prospect of a great success.

SOUTH STAFFORDSHIRE TRAMWAYS.

It is rumoured that the Board of Trade inspection of this new system of electric tramways is to be held within the next few days, and that soon after the public opening will be arranged. Of course, the technical arrangements so admirably carried out by Mr. A. Dickenson cannot yet be described, but we may venture to give a plan of the district through which the lines run, with the gradients that have to be surmounted. Walsall, the centre of the system, is in ancient records written Whaleshall and Walshale, and is supposed to have derived its name from its vicinity to an extensive forest wherein the Druids worshipped, and subsequently the Saxons, the latter erecting a temple to Woden—hence Wednesbury at no great distance.

Pleasantly situated upon the summit and sides of a limestone rock, watered by a small stream called by Erdeswick "Walsal Water," which falls into the Tame, Walsall is in the midst of a manufacturing and a mining district, ruled by men of energy and business capacity always seeking to improve means of communication and assist the workers of the district. It is not to be wondered, then, that this district adopted electric traction, and the system found favour which had succeeded so well in America — viz., the overhead system. More we cannot say at present, but await with interest the forthcoming inspection.



MAP OF THE SOUTH STAFFORDSHIRE TRAMWAYS.—The tramway line is shown by dots.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE INSTITUTION.

SIR,—The Institution of Electrical Engineers is the principal corporate representative of an important and increasing profession. In its early days, and especially when it existed as the Society of Telegraph Engineers, it was the principal exponent of the scientific aspect of electrical progress, and attracted a large number of gentlemen only indirectly connected with practical engineering.

Under those conditions it was appropriate that the Council should have been composed to some considerable extent of professors and similar representatives of purely scientific effort.

The Council, which has the responsibility of nominating its own members, has always given due, if not excessive prominence, to this idea, with the result that at the present time, notwithstanding that the membership now includes a very large number (in fact, a considerable majority) of electrical engineers actually engaged on important work, that body consists of:

10 actual or nominal professors.
4 physicists.
11 present or past representatives of Government departments, including naval and military officers.
7 electricians and electrical engineers.
—
32

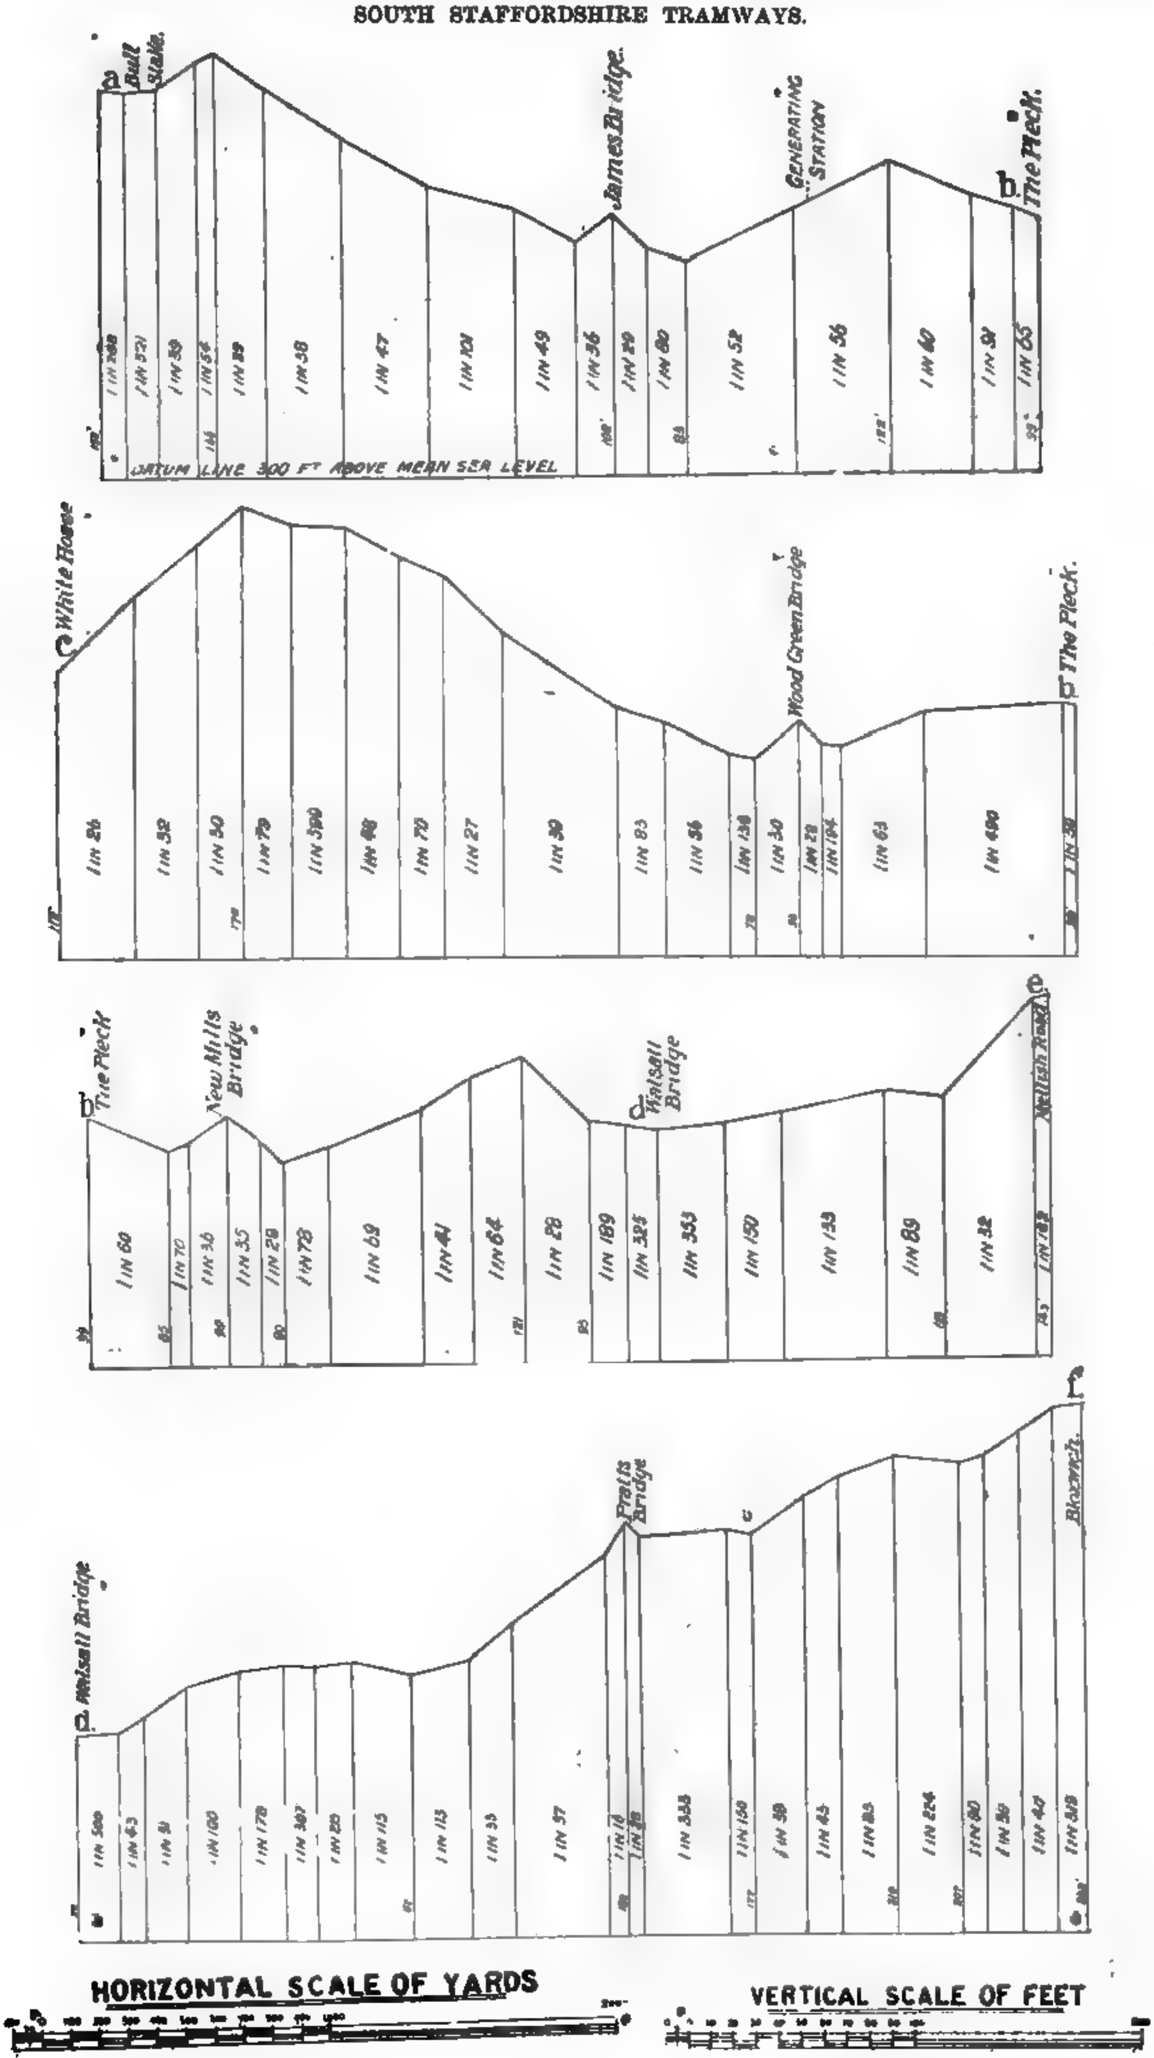
Or, omitting the vice and past presidents, it consists of

5 actual or nominal professors.
7 present or past representatives of Government departments, including naval and military officers.
3 electricians and electrical engineers.
—
15

From a consideration of the above list, which the most vivid imagination would have difficulty in recognising as representative of the present membership of the Institution of Electrical Engineers, we turn with relief to the Institute of *Civil* Engineers—an association which has earned the respect not only of this, but of all civilised countries, and whose principles and procedure may with advantage be imitated by other societies aiming at similar objects.

Their council is composed almost exclusively of engineers

SOUTH STAFFORDSHIRE TRAMWAYS.



Diagrams of Gradients.

in actual practice; it contains only six representatives of Government departments, and no professors.

It must not be considered from the above remarks that any professor who sits on the Council of the Institution of Electrical Engineers is not in every respect an ornament to that Council, and that his presence there does not give satisfaction to the whole body of members and associates; for we fully believe that the contrary is the fact.

In approaching this question we wish to deal exclusively with numbers, and we have neither intention nor desire to approach the subject from the point of view of the personal or contingent qualifications of individuals; for, notwithstanding that we, in company with other members, entertain a high personal regard for each and every member of Council, we feel that it is imperative, in the interest of the Institution, that that body should be truly representative, no class or interest predominating over others.

We have accidentally commenced with the professional element, but there can be no doubt also that the various departments of her Majesty's Government have at the present time a representation much in excess of their share in general electrical work, and that some of the seats held by both the above-mentioned classes might with advantage be distributed amongst other branches of the profession.

We know that our views as expressed above are shared by a large and influential section of the Institute, and we believe also by some members of the Council, who would have given effect to them had they been supported by any general expression of opinion.

We do not advocate, as politic or possible, the making of any immediate radical change in the constitution of the Council, but we do advocate a gradual modification of it by the nomination, on the part of the Council, of new members actively employed in constructive work to replace others retiring in rotation, until a more equal balance be attained.

As the date of the annual election is approaching, we have taken the liberty of bringing this subject forward through the medium of the Press in order that an opportunity may be afforded to members of the Institute of expressing their opinion on a subject which we are assured is attracting serious and increasing attention.—Yours, etc.,

R. S. ERSKINE. E. MANVILLE.
ALFRED E. MAVOR. JOHN RAWORTH.
A. A. C. SWINTON.

London, Nov. 7, 1892.

THE BRIGHTON AND HOVE ELECTRIC LIGHT COMPANY AND THE BRIGHTON CORPORATION.

SIR,—Your readers may probably have seen a recent leading article in the *Daily Telegraph* referring to the differences that have arisen between the Brighton and Hove Electric Light Company, Limited, and the Corporation of Brighton (copy enclosed). The chairman of this company, Mr. Robert Hammond, wrote a letter to the *Daily Telegraph*, which that paper did not publish. I venture, however, to send you a copy of this letter for publication, believing that the attitude of the Brighton Corporation is one of great moment, and of close interest to the members of the electrical industry.—Yours, etc.,

ALFRED S. HODGSON, Manager.

[COPY.]

To the Editor, "Daily Telegraph."

SIR,—In one of the leading articles of your to-day's issue you refer to the friction existing between the Brighton and Hove Electric Light Company, of which I am chairman, and the Corporation of Brighton. I feel certain that I may rely upon your known desire to set forth both sides of a question to afford space for the following explanation of the electric lighting question at Brighton.

I may remind your readers that, as an almost universal rule, whenever a corporation has determined to take into its own hands the supply of gas, water, or electric lighting, it has taken over at a valuation the works of the private company that has hitherto had such supply in its hands. The only exception that has been made by any corporation in this country up to the present moment has been made *by the* Corporation of Brighton, the exception being in connection with this very electric light supply to which you refer.

Now, Sir, I think I may say that, however, politicians may differ as to the wisdom of corporation trading, they are all agreed upon the principle that when a corporation determines to engage in an industrial undertaking, it should take over on mutually equitable terms the private concern already in existence which has done the pioneering and established a goodwill.

Up to the present time, at all events, no one has proposed in the case of gas or water companies that corporations should start opposition works and squeeze out the existing concerns by the sheer force of opposition and by a lavish expenditure of the ratepayers' money.

The Brighton Corporation, however, composed, strange to say, principally of tradesmen with very keen notions individually of the sacredness of private rights, hold as a corporate body exactly opposite views, and though the Brighton Electric Supply Works, which my firm founded in 1881, has during the past 10 years fully coped with all demands for electric lighting in Brighton and Hove, the Corporation of Brighton a year ago actually started opposition works, and refused to treat with the Brighton and Hove Electric Light Company on any terms whatever for the acquisition of its undertaking. No wonder that men conducting their business on these lines shut their eyes to the real interests of the town in other directions.

In your leading article you draw attention to the neglect of the Brighton Corporation to light the magnificent sea frontage with the electric light, and you will doubtless be surprised to hear that the company of which I am chairman has made two offers to light the sea-frontage in Brighton, the last offer being dated 6th March, 1890. The offer being to charge the Corporation for the lighting *the same price as gas*, both of which offers were declined with thanks.

You state in your article that the Brighton Electric Light Company is seeking to extend its area of lighting, but if you will grant me a little more of your space I should like to lay before the public the exact facts, as making them public will, I am sure, tend to get justice for the enterprise which the Corporation of Brighton are trying to stamp out.

No application whatever is being made by the company to extend its area, for ever since 1881 the Brighton Electric Light Company has not confined the electric light supply to any particular portion of the town, but has run its wires in every direction wherever the demand arose, the circuit at one time measuring 30 miles.

I may remark, *en passant*, that during all these years the Corporation, which obtained parliamentary powers as far back as 1883, neglected to do any work whatever, and left the company in possession of the field to work up the business.

The undertaking having been started at such an early period of the electric lighting industry, the engineers followed the then universal custom of placing the cables overhead, but in 1888, after being requested so to do by the Board of Trade, consequent on a report made by one of their inspectors, the company made application for a provisional order to place its cables underground. The Corporation, however, not consenting to the granting of the order, the Board of Trade held a local enquiry in April, 1889. No evidence whatever, it may be stated, was tendered by the Corporation of their intention, within a reasonable time, to fulfil the obligations of their provisional order granted to them in 1883. On the contrary, the Corporation opposed the grant of the order to the company upon the grounds that electric lighting was in an experimental stage, that no system was reliable, and that when such was discovered the Corporation intended to supply the light themselves, under the order which had been granted to them, and which, up to the date of the enquiry, and indeed till July, 1889, had been a dead letter.

The result of the enquiry was that the inspector reported in favour of an order being granted to the company for Brighton, but after the enquiry was closed, and when the company had not an opportunity of being heard, or cross-examining, the Corporation sent a deputation to the Board of Trade to assure the President of their intention to carry

out the provisions of their order, and upon which representation the company was refused the order which they had been invited to apply for, and upon the faith of obtaining which they had spent a considerable amount of money in advertising the usual notices, engaging counsel and witnesses to appear at the local enquiry, and other professional assistance.

Upon the order being refused, the Corporation, abandoning their contention that electric lighting was an experiment, advertised for tenders for works to supply the electric light to a small area of the town where the bulk of the company's consumers were situated. Tenders having been received, the Corporation applied to the Local Government Board for sanction to borrow some £30,000, and an enquiry was held at Brighton in April, 1890, by the Local Government Board. At this enquiry the company appeared and stated their case. A petition signed by nearly 10,000 ratepayers was also presented by Mr. J. L. Wood in opposition to the scheme. A very strong minority of the Corporation was also opposed to the sanction and expenditure of such a large sum of money in this direction, as it was pointed out and proved to the inspector that an advantageous offer had been made to the Corporation by the company. The proposed expenditure by the Corporation was, however, sanctioned, and the Corporation works erected. The Town Council confidently expected that the opening of the works a year ago would result in the immediate ruin of the company, but, to the surprise of the Corporation officials, the company has gallantly held its ground, beating the Corporation at every point, and actually doubling its business during the past 12 months.

On the other hand, the company is able to say that since its applications, commencing in 1889, for provisional orders, the directors have made every endeavour, as originally suggested by the Board of Trade, to come to terms with the Corporation. Last autumn (1891) they succeeded so far as to enter into a draft agreement with the Lighting Committee of the Corporation for the purchase by the Corporation of the goodwill and undertaking of the company so far as it related to the supply and sale of the electric light within the borough. The draft agreement was submitted to the Corporation by the Lighting Committee with a strong recommendation for its acceptance, but the Corporation, although the majority of its members have admitted that the company have done the town a great service during the years they have been established, refused to sanction it, and only last Monday, to more effectually try to crush the company, the Corporation have resolved to further extend their area, and to apply to the Local Government Board for a further loan.

This most recent move of the Brighton Corporation has doubtless been caused by the appearance of the statutory advertisement of the company giving notice of its intention to again apply in the coming session to the Board of Trade for a provisional order.

I am sure that the public, with the facts before them, will join with me in the hope that the company's order may be granted, and that the Board of Trade will not, by refusing the order, assist a Corporation armed with statutory powers, and backed by practically unlimited credit, to work a gross injustice by destroying a trading company already weakened by the heavy expense of supplying light through its experimental stages, and a company which has been of the greatest service to public and private consumers in the borough during a period of 10 years, and during a time when the Corporation, though they possessed statutory rights to supply electricity, failed to put them in force.—I am, yours obediently, R. HAMMOND.

Chairman, Brighton and Hove Electric Light Company, Limited.

From the "Daily Telegraph," November 2, 1892.

"The Brighton authorities do not appear to realise the responsibilities of their position. Already they have won an unenviable fame as being a long way more retrograde and dilatory than most of their rivals in other seaside towns. What visitor to Brighton, for instance, does not come away mournfully impressed with the opportunities lost along the sea-frontage, the ugliness of the piers, the ridiculous inadequacy of the Aquarium, the mean aspect of many of the streets, the pitiable squalor of the beach? Hastings, St. Leonards, Eastbourne, Portsmouth, are all handsomely lit with the electric light. Why does the magnificent range of three miles—from Hove at one end to Black Rock on the other—present so cheerless an aspect of struggling and flickering gas lamps? The recent meeting of the Brighton Town Council gives us some explanation of problems like these, and sheds on the parochial intelligence of the authorities a far clearer light than they are at all inclined to afford to the inhabitants of their benighted city. It seems that considerable jealousy exists between the Corporation and the electric lighting company. Both supply houses and shops in certain districts already, but both are now applying for extended powers to increase the area of their operations. In their mutual bickerings it is needless, perhaps, to say that the public in general and the ratepayer in particular are sent to the wall, and left to console themselves with the reflection that London-by-the-Sea is more painfully neglected—we will not say than any other town of the same size, but than any watering-place of any pretensions. Nobody expects the Corporation of Brighton to consist of practical electricians. Perhaps most people would be satisfied if they only showed themselves men of common business capacity. If, however, they feel themselves unable to solve the question of how the town they misgovern should be lighted, let us recommend them to pay a visit to St. Pancras, where the electric light not only illuminates the thoroughfares and private establishments with wonderful brilliancy, but is also supplied at a rate which occupiers of houses in other quarters of London often find themselves constrained to envy."

INSTITUTION OF ELECTRICAL ENGINEERS

The first meeting of the autumn session of this Institution was held last night at the Institution of Civil Engineers, Great George-street, the president, Prof. Ayrton, F.R.S., in the chair.

Before the ordinary business of the meeting, which was the discussion of Mr. Swinburne's paper on "The Problems of Commercial Electrolysis," which appeared in our issues of September 30, October 7, and October 14 last, the PRESIDENT briefly alluded to the loss sustained by the society in the death of Mr. Edward Graves, who was treasurer for many years and not long since president.

GENERAL WEBBER moved a resolution expressing great sympathy with Mrs. Graves and the family. General Webber referred to his recollections and to those of his colleagues of the late Mr. Graves in every position which he had held. Every colleague looked upon him not only as a superior but as a friend. He was quite sure that this resolution of sympathy with Mrs. Graves would meet with cordial support.

Mr. SPAGNOLETTI seconded the resolution, and corroborated all that General Webber had said of the late President.

The funeral, the PRESIDENT said, was at Hammersmith Cemetery on Saturday, 12th inst., at 11 o'clock.

The resolution was carried unanimously, and the secretary was requested to convey the terms of the motion to the family.

Mr. Cooper opened the discussion on Mr. Swinburne's paper, saying the thanks of the members were due to Mr. Swinburne. Mr. Cooper had for years been connected with the Hermite system, and thought that the members would like to hear a description of a going concern that was a success. That process was first shown at the Antwerp Exhibition. Experience then showed that the apparatus was not practical. Subsequently Mr. Hermite, in conjunction with Mr. Cooper, designed the present apparatus. [This has been described in our columns]. Platinum gauze in ebonite frames is used as the anode. In practice it is found that there is no attack on this anode. In six years' working not more than one anode has had to be replaced. Diagrams of the apparatus were shown. Experience shows that the conditions in actual practice are continually varying, and the matter is not so simple as theorists imagine. In the electrolysis 1,000 volts and 5 amperes is the usual electrical condition for electrolysing the magnesium chloride solution. He hoped some day to contribute a paper dealing completely with the subject. The present electrolyser is the survival of the fittest. They had tried to use carbon, but

found it disintegrated, and gave blacks to the pulp which certainly was not bleaching. The use of copper had to be avoided, because it dyed the pulp green, and so on with other materials.

Mr. Falkenstein referred to the use of electricity in tanning, and contended that the endosmosic flow going on when the current was used hastened the action of tanning.

Mr. Stepney Rawson would say a word with regard to one or two points in the paper. Mr. Swinburne's cost of a kilowatt-hour is put at a farthing, and thought to be a ridiculous cost, but Mr. Rawson hardly thought this was correct when applied to commercial electrolysis. Mr. Rawson thought Mr. Swinburne wise in stopping at the dynamo terminals when considering cost, but if leakage and parasitical currents were concerned, a farthing was too little. He had tried carbon, but only under certain conditions, and when least expected would it work. With regard to zinc and lead and the difficulty in treeing, the process used with the Elmore burnisher removed that difficulty.

Mr. Cross, who had been interested in the Hermite process since its introduction, referred to the discussions which had occurred between Mr. Hermite and Dr. Hurter as to the exact chemical and mechanical effects which went on in the process. The essential matter in dispute was the ratio of bleaching accomplished—that is, the chemical work done to the watts expended. The amount of bleaching that could be carried out by one ton of bleaching powder at a cost of £7 or £8 could be done be done by electrolytic means at from £2 10s. to £4. Dr. Hurter stated that from his experiments the cost was £22 to £40. It was evident that there was something quite wrong here, and not a mere discrepancy. In their own experiments (Hermite) they had found that 90 per cent. of the theoretical effect was obtained. Since then they had carried out an experiment and found in ordinary conditions, instead of having simply oxidisation, there was also chlorination. Even in laboratory experiments, 14 per cent. went in by-paths, while with the Hermite process there was no such loss. These facts went to prove that electrolytic bleaching might be more economical, but the economy depended on the conditions present. He added that in French paper mills, certainly as scientific in their processes as our own, the Hermite process had been working for five or six years, and had given continuous satisfaction, and it must, therefore, be pronounced a commercial success.

Prof. Perry thought it would be desirable to have actual figures of the cost of the electrolytic as compared to the bleaching process.

Mr. D. Fitzgerald thought the thanks of the members, especially the younger members, should be given to Mr. Swinburne, for bringing forward a subject so likely to become so important as that of electrolytic processes. With reference to the material to be employed as anodes, he referred to the use of lithanode, which was perfectly indifferent to hydrochloric acid so long as the action continued. He showed a piece of lithanode used that day for nine hours in hydrochloric acid for producing chlorine. In conjunction with Mr. Faulkner, who had large experience, he had come to the conclusion that chloride of magnesium as a substance to be electrolysed was impracticable. Experiments had shown that after exposure to the solution for a long time the lithanode became coated with a white substance which suggested chloride of lead, but was really a magnesium hydrate, as could be seen by scraping, when the peroxide beneath is intact. The fact was extremely important in bleaching, and would confirm what had been stated as to abnormal power expended in electrolytic bleaching. In experiments he had since conducted with Prof. Perry and Prof. Meldola they were surprised to find that there did not seem to be any strict proportion between the current used and the resultant chlorine produced. His own assistant, Mr. Burman, a rising electro-chemist, had carried out experiments for him on this point, watching hour by hour the effect produced in such electrolytic action, and had found that after a certain strength of chlorine had been produced, that there seemed to be a cessation of action, and even an actual disappearance of the gas. The fact fact appeared to be that chlorate was formed in considerable abundance at ordinary temperatures, and he therefore thought that the use of magnesium chlorate would have to be given up. This transformation would probably account for the failures that had hitherto been unaccountable. They could no doubt be attributed to the undesired formation of chlorates. He would point out, especially to the younger members, the very many openings that might be opened up by electrolytic processes of dealing with chemicals. He would quote as instances the conversion of arsenious acid into arsenic acid by electrolytic means in considerable quantities. Again, the conversion of ferro-prussiate of potash into the ferri (red) prussiate, the purification of sulphuric and hydrochloric acid by the elimination of lead and iron or other impurities.

Mr. Faulkner, who has been engaged with Mr. Fitzgerald in these experiments on bleaching for several years, stated that the lithanodes shown to the members had been in constant use for three years, while some had been in use as long as four years. Prof. Perry and others had been asked to witness some abnormal working which was not thoroughly understood, but which he thought Mr. Fitzgerald rightly attributed to the formation of chlorates. It was on account of this abnormal working that he agreed with Mr. Fitzgerald that magnesium chloride was not the best, nor by any means a suitable material for electrolysing for bleaching purposes.

Mr. Swinburne asked whether oxide of magnesium always appeared on the plates, but not getting a direct answer, he asked whether the appearance of the lithanode plates differed when used in the vertical position to what they did in the horizontal position.

Mr. Faulkner replied by pointing out that a part of the exhibit consisted of plates which had been used vertically.

Prof. S. Thompson thought the discussion of commercial problems without actual details of cost a waste of time, and agreed that the difficulties experienced could not always be foreseen in the laboratory. He referred also to processes failing, not because they ought to fail, but because of the way in which they were carried out, giving as an example a paper mill, in which electrolytic bleaching had been abandoned because the bleaching and dyeing of the pulp were attempted in the same vat, the result being it proved too costly for dye. He then referred to the real want of knowledge of many processes when the intermediate actions had not been thoroughly examined, and to the greater activity of chemicals in the nascent conditions. In all cases the minimum E.M.F. required for a particular purpose should be known, as often too great E.M.F. was a defect, and stopped the action. He also referred to the difference between cyclic and non-cyclic processes, the former often being commercially practicable, while the latter was not.

The discussion was then adjourned to the 17th inst.

ABSTRACT OF REPORT ON TRIALS OF PARSONS'S CONDENSING STEAM TURBINE, USING SUPERHEATED STEAM.

BY PROF. EWING, F.R.S., M.I.C.E., CAMBRIDGE UNIVERSITY.

In December last I carried out a series of trials of Mr. C. A. Parsons's new condensing steam turbine, to determine the consumption of steam under various grades of output (vide *E. E.*, vol. ix., p. 34). The machine tested was a steam turbine coupled with an alternate-current dynamo, capable of an output at the rate of 100 kilowatts, or 100 Board of Trade units of electrical energy per hour. It was then found that the consumption of steam was 37lb. per electrical unit when the machine was running under its full load of 100 units per hour, 50lb. per unit when the load was 50 units per hour, or one-half of the full value, and [illegible] per unit when the load was reduced to one-third of its full value.

I have now to report the results of a further series of trials made during the present month, with the object of testing how far the efficiency has been improved by certain recent changes and by the use of superheated steam. The same turbine was used in these as in the former trials, but some additional rings of turbine blades were inserted at the high-pressure end to enable it to deal more effectively with pressures up to 115lb. per square inch (absolute), the vacuum was improved by the use of a larger air pump and by admitting the injection water at a point of the exhaust pipe close to the turbine, and there was a new governor. The main factor in the improvement which has now been brought about is, however, the use of moderately superheated steam. The improvement demonstrated by these new trials is very marked. Thus, in the present turbine with steam superheated [illegible] above the temperature of saturation, the gross amount of feed water is 28.4lb. per electrical unit generated when the machine is working at full load, and 32lb. per unit at half load. By raising the superheating further (to 125deg. F. above saturation) the consumption at full load is reduced to 27lb. per electrical unit. Comparing these figures with those of the former trial, it will be seen that the consumption of steam has been reduced by about [illegible] per cent. What makes these results specially important is the consideration that there is nothing in the construction or working of the turbine to make it likely that the use of superheated steam will be attended by any drawbacks such as have been experienced in engines of the ordinary type. The steam works without friction, it comes into contact with no rubbing surfaces, and there is no packing to be injured. [Here comes a description of the engine which we need not reproduce.]

The governing of the machine tested was accomplished by a novel and extremely effective appliance. Steam was admitted to the turbine in a series of gusts by the periodic opening and closing of the double-beat lift valve. This valve was operated by means of a steam relay in mechanical connection with the turbine shaft, so that the valve was opened regularly once in every [illegible] revolutions of the shaft. The duration of each gust was controlled by an electric solenoid, which was connected as a shunt to the field magnets, but was compounded so as to keep the volts constant. The core of the solenoid was hung from the end of a long lever. The fulcrum of this lever was periodically moved up and down by means of a link connecting it with the eccentric which also served to drive the oil pump. The other end of the lever controlled the valve of the steam relay. Each periodic movement caused a gust of steam to be admitted to the turbine, the duration of the gust depending on the height of the distant end of the lever. The effect was, that at full load the gusts became blended into an almost continuous blast, the valve closing only momentarily, or not at all, in each of the periodic movements; under any lighter load each interval of admission alternated with an interval, during which the steam was completely shut off. The action of the governor was most satisfactory. The periods of admission were so frequent that they caused no material throbbing of speed nor any variation of volts sensible on a voltmeter. There was no hunting, and the freedom from friction was greater than I have seen in any governor. I repeatedly threw the whole load, amounting to over [illegible], on and off suddenly, without causing more than a momentary variation in the volts. The governor was sensitive, quick, and certain in its action to quite an exceptional degree.

By applying an indicator at the admission end of the turbine chamber, below the double-beat valve, observation was made of the pressure during the periodic admission of steam; this was done by pulling the paper-drum of the indicator as steadily round as possible by hand while the pencil rose and fell. Figs. 1 and 2 are examples of diagrams obtained in this way. In Fig 1 the load was about one-half the maximum; in Fig. 2 it was about three-quarters The pressure which these diagrams show during admission is about 4lb. less than that shown at the same time by a pressure gauge on the steam-pipe above the governor valve.

The machine tested was primarily constructed to generate alternate currents up to 50 amperes, with a potential of 2,000 volts, and in some of the trials the original alternate-current armature was used. But thinking it desirable to make the tests of efficiency depend on measurements of continuous rather than of alternating currents, in order to avoid any uncertainty which may be held to attach to estimates of the work spent in an alternate-current circuit, I suggested to Mr. Parsons the desirability of winding a continuous-current armature specially for these trials He adopted the suggestion, and most of the trials have accordingly been made with a continuous current armature, wound to give 400 amperes at 250 volts. The original exciter was still used to supply current to the field magnets.

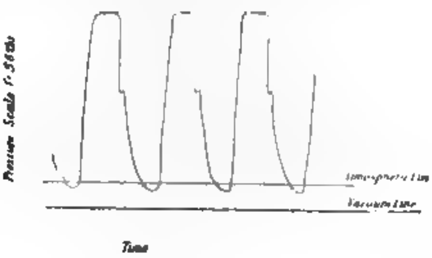


FIG. 1

It may be said at once that the results of the continuous current trials, where the electrical measurement of the work done is of a perfectly simple and straightforward character, are in close agreement with those of the alternate-current trials.

The main armature was about 2ft. 6in. long over the body by 9in. in diameter. The weight of copper on it was only 33lb., or ¼lb. per kilowatt of output.

Steam for the turbine was supplied, at a pressure of 100lb. per square inch by gauge, from a locomotive boiler which was capable of giving enough for the full load of 100 units per hour. The feed-water was measured by putting it through a tank, the graduations and total capacity of which I checked by weighing water into it. The contents of this tank were delivered into a second tank, from which the feed-pump drew its supply, and in which the level of the water was adjusted to have the same value at the beginning and end of each period of observation. The level of water in the boiler was kept as nearly as possible constant throughout.

In all the statements which follow of the results of these trials the quantity of feed-water named is the gross quantity supplied to the boiler, no deduction having been made for leakage, blow off at the safety-valve, or other loss.

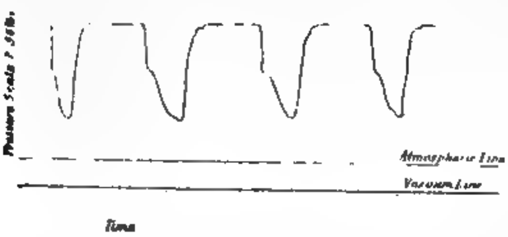

FIG. 2.

On its way to the turbine the steam passed through an improvised superheater consisting of eight 9ft. lengths of cast-iron pipe, 8in. in internal diameter. This superheater was placed in the main boiler flue, and except in a special series of trials noted below, was heated merely by the hot gases from the boiler tubes The draught was forced by a steam jet from an auxiliary boiler. Notwithstanding the small size of the improvised superheater, this sufficed to bring the steam from 338deg. F., the temperature of saturation, to about 400deg. F. In a special series of trials extra superheating was produced by lighting a furnace built for that purpose in the brickwork enclosing the superheater. With the help of this furnace the temperature of the steam in these special trials was raised to about 465deg. F.

Three separate sets of trials were made, August 11 to 15, 1892. In the first set the steam was superheated by means of the hot gases from the boiler furnace only. The temperature approached but did not exceed 400deg. F., which, as the boiler pressure was 100lb. per square inch above the atmosphere, corresponds to about 60deg. of superheating. In this set of trials the continuous-current armature was used, and the amount of feed-water was determined for six different grades of output, from no electrical load up to a load in which the output was at the uniform rate of 102 Board of Trade electrical units per hour, the current being spent on a bank of coils. The results of this set of trials are set forth in Table I, below. The output stated is the amount of electrical work done upon the external circuit, and does not include the output of the exciter. The volts were measured by three Cardew voltmeters, which were tested against each other, and one of them against a Thomson balance. The amperes were measured in the following way: A low-resistance frame consisting of many bare thick wires of platinoid grouped in parallel was arranged as a shunt to a mirror galvanometer, which was provided with a strong controlling magnet, so that the whole current of about 400 amperes could pass without causing an inconveniently great deflection, and without heating the wires of the shunt materially. In series with this was placed (1) an Evershed ampere-meter which had been carefully calibrated by reference to a Thomson balance, and (2) two Siemens's electro-dynamometers, one of which could take the strongest current while the other was suitable for comparatively weak currents only.

TABLE I.—Trials with Continuous-Current Armature, with Steam superheated by the Gases from the Boiler Fire only.

Pressure by gauge on boiler, lbs. per sq in.	Temperature of steam, deg. F.	Load in electrical units per hour.	Feed-water per hour in lbs. Total.	Per unit.
96	335	0·1	480	—
102	365	10·2	760	74·5
100	356	27·0	1,110	41·1
102	400	49 2	1,590	32·3
100	390	74 5	2,170	29·1
103	398	102·0	2,900	28 4

Vacuum in full-power trial: By mercury column at exhaust, 27½in; by gauge on condenser, 28¼in. Barometer, 29·9in. Temperature of injection water, 73deg. F. Speed 4,500 revolutions per minute.

The constant of the shunted mirror galvanometer was determined in the low-power trials by comparing its deflection with the readings of the Evershed and of the more sensitive of the two Siemens's instruments. These were then cut out to allow stronger currents to pass, and in the trials under heavy load a further check on the constant of the mirror galvanometer was furnished by the readings of the larger electro-dynamometer. The mirror galvanometer, the constant of which remained unaltered throughout, served to connect the readings of all the currents, from the lightest to the heaviest loads The agreement between the various measurements was perfectly satisfactory.

(To be continued.)

LEGAL INTELLIGENCE.

HOPKINSON v. ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY.

Alleged Infringement of Patent.

We must postpone notes of the evidence in this case—if notes are required—for a future issue. As a matter of fact, the case was somewhat abruptly adjourned on Monday because of the startling evidence produced by the defendants. After the examination of Mr. Crompton and Mr Raworth, Mr. J. E H. Andwews was put into the box, and his evidence completely took the plaintiffs by surprise, whereupon they asked for an adjournment for a week to consider the evidence and their position—that is, to consider whether the case is to continue or not. Mr. Andrews's evidence was to the effect that he had publicly used the three-wire system at Glasgow prior to the plaintiff's patent.

COMPANIES' MEETINGS.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.

The twenty-fourth ordinary general meeting of the Western and Brazilian Telegraph Company, Limited, was held yesterday at Winchester House.

Mr. W. S. Andrews, chairman of the Directors, presided, and moved the adoption of the report and accounts for the half-year ended June 30, 1892. He stated that they had realised their anticipations of a decrease of revenue owing to the adverse state of exchange in Brazil. This was a cause over which they had no control. Another circumstance with which they had had to reckon was a reduction of the tariff. Of the decrease of £20,940 in revenue, no less than £15,539 was due to loss on exchange The increase in the working expenses was due partly to an exceptionally sickly season, and a consequently large doctor's bill, and partly to accidents to their vessels and the necessity of hiring others. For the first time, also, they had had to meet a falling off of business. The excitement of a few years had ceased, and there had been commercial stagnation, from which their Company suffered. Their consolation was that there were already signs of improvement in this respect, and that the exchange, which had been 11½d., was now 1s. 1d., or 1s. 2d. In laying loop and other lines, the Directors had spent the reserve fund—a course which the shareholders had constantly urged upon them The interest from this reserve fund had of course disappeared, and in place of it they had an addition that nearly doubled the whole system, and that actually doubled it between Pernambuco and Montevideo, which was the revenue-earning portion of the line. A small debit balance was carried forward, but hitherto the Directors had not dealt in the deben-

tures which they had power to issue. The competing lines would find it difficult to overcome a service by which they were able to send telegrams from Brazil to London in an average of 30 and 56 minutes.

Mr J Coppes seconded the motion, and it was carried

A dividend equal to 2 per cent per annum was declared, and the proceedings closed with a vote of thanks to the Chairman and the Directors

NEW COMPANIES REGISTERED.

Dominion Electrical Company, Limited — Registered by F. A Rohder, 14, Mincing lane, E C , with a capital of £25,125 in 5,000 £5 ordinary shares and 500 5s. founders shares Object to carry on the business of a telegraph, telephone, and electric light, heat, and power company in all its branches There shall be five directors, the first to be elected by the signatories to the memorandum of association. Qualification, 50 ordinary or 10 founders' shares. Remuneration, £1,000 per annum, divisible

Julius Sax and Co., Limited Registered by W B Styer, 2, Threadneedle street, E C , with a capital of £20,000 in £10 shares Object to acquire the undertaking of producers and suppliers of electricity hitherto carried on by Julius Sax and Co , and to develop and carry on the said business in all its branches There shall not be less than two nor more than five directors , the first to be elected by the signatories to the memorandum of association Qualification, 100 shares or £1,000 debentures Remuneration not to exceed £500 per annum, divisible

New British Electric Installation Contractors, Limited - Registered by Jordan and Sons, 120, Chancery lane, W C , with a capital of £25,000 in £5 shares. Object to acquire the undertaking hitherto carried on at Worcester by the British Electrical Installation Contractors, Limited, in accordance with an agreement expressed to be made between the said company of the one part and the present Company of the other part , generally, to carry on the business of electricians and electrical engineers in all its branches. There shall not be less than three nor more than five directors , the first to be elected by the signatories to the memorandum of association Qualification, £50. Remuneration, £250 per annum, after payment of 6 per cent. on the paid up capital.

BUSINESS NOTES.

Direct Spanish Telegraph Company. —The receipts for October were £2 307, against £2 436

Great Northern Telegraph Company. —The receipts for the month of October were £24 000.

Burton on Trent The authorities propose to obtain sanction for a loan, part of the proceeds of which is to go for electric lighting purposes

Asylum. —The new asylum at Charminster being erected for the Dorset County Council, at the cost of £84,000, should be lighted by electric light.

Edinburgh The pet scheme of Prof Forbes refuse destructors for Edinburgh is being discussed by the Lighting Committee of the Town Council.

Design for Motors. The sum of £10 is offered for the best design for electrical motors. Particulars will be found in our advertisement columns.

Phonophere Company, Limited —This Company has removed its offices from Blomfield House, London wall, E C to Faraday House, Charing Cross road, W C.

Manchester Infirmary. —The Manchester Royal Infirmary Board of Governors have appointed a sub committee to consider the lighting of the infirmary by electric light

Bolton Tramways As will be seen from our advertisement pages, the time has been extended to December 12th for tenders to be received for a lease of the Bolton and suburban tramways

West Bromwich —At the annual meeting of the Council the Estates Committee reported that the Mayor had arranged to provide a temporary installation of the electric light if the Corporation would provide the engine power

Cologne. The price of current at Cologne is equal to 9 6d. per B T U , with discounts from 2½ to 40 per cent. It is expected that the price may soon be lowered The price of gas in Cologne is equal to 3s. 8d. per thousand cubic feet

Lynton —At the monthly meeting of the Lynton Local Board the clerk was instructed to inform the Lynton Electric Lighting Company that as soon as they were in a position to furnish light their application for powers should be granted

City and South London Railway Company —The receipts for the week ending November 6 were £891 against £783 for the corresponding period of last year, or an increase of £108. The total receipts for 1892 show an increase of £1,407 over those for the corresponding period of 1891

Coventry —At the annual meeting of the City Council, held on Wednesday Councillor George Singer was re elected mayor and in replying, referred to the fact that estimates for electric lighting had been received, and that the councillors had under consideration a scheme of electric traction for tramways

Chiswick. At the Chiswick Local Board meeting last week, with reference to the contract with Messrs. Bourne and Grant for electric light in Chiswick, the clerk stated that he had called at the offices of the Board of Trade, and was informed that that Board hoped to send the draft deed very shortly

Electric Railway to Barry Island A special meeting of the directors of the Barry Railway Company was held last week at the general offices, Barry Dock, when the scheme for the construction of an electric railway to Barry Island was naturally discussed, and it is expected the work will be taken in hand forthwith

Auction Sale. On page xvi of our advertisement sheets will be found an announcement relating to a sale of electrical and engineering plant, tools stock fittings stores etc Full particulars are given, and catalogues can be obtained of the auctioneers, Messrs Wheatley Kirk, Price, and Goulty, 49, Queen Victoria street, E C.

Stafford At the last meeting of the Town Council, a communication from the County Council stated that they had under consideration the question of introducing the electric light in the new County Buildings and asked what facilities the Council could offer in the matter The question was referred to the Electric Light Committee.

Friern Barnet At the last meeting of the Local Board Mr Hennessy suggested that the district be lit by the electric light instead of gas Mr Baldwin Latham had stated that the [illegible] at the sewage works could be utilised for the purpose, with an expenditure of about £500 The matter was referred to the Works Committee for consideration

Derby —The Derby Town Council have accepted the tender of Messrs Siemens Bros and Co , Limited of London, at £[illegible] for providing, delivering fixing, testing setting to work and maintaining combined steam engines, alternating and constant current dynamos, condensers and other machinery and apparatus necessary for the production of electric light

Blackpool The Corporation of Blackpool invite tenders for the installation of wires, switches, etc for the electric lighting of the new police station buildings in that town Plans specifications, and form of tender may be obtained on application to J Wolstenholme, borough engineer, Town Hall, Blackpool Tenders to be delivered at the Town Hall on or before November 25, 1892

Melbourne. —The National Bank of Australasia and the Commercial Bank of Australia, the bankers of the Corporation of the city of Melbourne, Victoria, having purchased the debentures, invite applications for a 4 per cent loan of £[illegible] of the city of Melbourne, the price of issue being 98 per cent. The loan is to be applied for the purposes of electric lighting of the city and the extension of the baths and markets

Lundberg Switches We note that, owing to the great demand for Unique switches Mr A. P Lundberg has been obliged to make great alterations at his works at Kingsland whereby to increase his staff and so better keep pace with the increasing demand Already, over 15,000 of these switches have been supplied and considering the very short period they have been on the market, it evidently shows they are greatly appreciated

Hamburg The installation for Hamburg, to be erected by Schuckert and Co , is to be on the continuous current system The municipality has arranged what is considered a satisfactory scale of charges namely, 9½d per B T U for private lighting, half that for industrial purposes, with discounts for large consumers up to 30 per cent The town is to have one fifth of the gross income, and a sliding scale share of profits if these exceed 6 per cent

Bristol The Bristol Urban Sanitary Authority invite tenders for the supply delivery, and erection of underground feeder mains, arc light circuits, junction and house boxes, arc lamps posts and suspension gear Tenders must be made on the prescribed forms, and delivered at the offices of the Authority, 51, Prince street, Bristol, on or before Thursday, December 1. A fee of £2 is required for specification and form of tender, to be returned on receipt of bona fide tenders

West-end Lighting The following is a list of work being done by the Electrical Supplies and Fittings Company, Limited, in the West-end House installation for Lady Sarah Heron, 2, Connaught place W ; H Davison, Esq , 3 Penywern road, S W ; C F Members, Esq , 2, Morton gardens, S W , the [illegible] Company, 74, New Oxford street W , St Jude's Church extension of lighting in schoolroom, West Kensington ; A L [illegible] Esq , 11, Bramham mansions, S W.

Leicester Alderman Lennard, at the monthly meeting of the Leicester Town Council, said the committee had been in hopes they would be able to bring the electric lighting question forward, tenders from 13 firms having been received, but they found on going into the tenders that they were of so technical a character, and required so much careful examination, that they were not prepared to bring a definite resolution forward They hoped to be able to do so at the November or December meeting

Poplar The Poplar District Board of Works have intimated their intention of applying to the Board of Trade for a provisional order enabling them to produce and supply electric light for public and private purposes within their district It is proposed to lay electric mains in the East India Dock road, Robin Hood lane, High street, Poplar, and North street, Bow road, Coborn road, [illegible] road and Fairfield road The provisional order if granted will subsequently have to be laid before Parliament for confirmation

Pontypool. In connection with the Pontypool Electric Light and Power Company, by the invitation of Mr W [illegible] about 90 gentlemen, representing the commercial and public interests of

the county, were entertained at luncheon at The Crown Hotel, Pontypool, on the 2nd inst. Mr. W Pegler presided, and was supported by Mr. I. Butler, J P., Mr. D. A. Vaughan, of Newport, and others. Mr. J. C. Howell, electrical engineer, Llanelly, occupied the vice-chair, and was supported by several prominent Newportonians.

West India and Panama Telegraph Company, Limited.—The report for the half-year ended June 30 states that the revenue was £44,148 against £47,641, and the expenses £28,589 against £24,868. The balance, with £2,122 brought over, makes a total of £17,682. The directors propose to pay interest of 6s per share on the first and second preference shares, and a dividend on the ordinary shares of 6d. per share, tax free, £3,704 being carried over. The receipts of the Company for the half-month ended October 15 were £2,072.

Paisley.—A very lame and impotent conclusion has been arrived at in the Paisley Town Council with reference to the electric lighting. A report was laid before the Council from the Electric Lighting Committee, stating that they had not seen their way to recommend the Council to proceed with the laying down of an installation for the lighting of the town under the order obtained last year, the probable demand for the light not being sufficient to warrant the expenditure involved. It was remitted to the Electric Lighting Committee to further consider and report.

Burnley.—At Wednesday's meeting of the Burnley Town Council, authority was given for the acceptance of the following tenders in connection with the erection of the electric lighting plant: The Oldham Boiler Works Company, for boilers, at £700; E. Green and Son, Manchester, for economisers, at £228; Job Isles, Stanningley, for cranes, at £195; Callender's Bitumen Telegraph and Waterproof Company, London, for cables, at £4,537; the Burnley Iron Works Company, for engines, at £1,600; and the Electric Construction Corporation, Limited, Wolverhampton, for dynamos, accumulators, and switchboards, at £2,056.

Windsor.—The question of the use of turbines for the electric lighting of Windsor is occupying the local papers. Councillor Dyson has advocated their use, and Mr. Fox retorts, in turn, that if the turbines are big enough to use in this way, there was waste of money in putting them in; if not, there is not too much spare power to deal with the water supply. Mr. Dyson's proposal was to use the water power on Tangier Island, and add steam power sufficient to give constant supply to Windsor, Eton, and district, keeping the powers in the hands of the Corporation. He promises a report upon the amount of power to spare and needed.

Shop Lighting in Dublin.—Messrs Clery and Co., of Sackville-street, are the first of the large drapery firms in Dublin to introduce the electric light into their business premises. Their whole establishment was illuminated with the new light last Saturday night, and the change made a marked improvement, more particularly with reference to judging of colours. There are throughout the warehouse 18 arc lamps of the Brockie-Pell type; also 12 32-c.p., 17 25-c.p., and 19 16 c.p. incandescent lamps. The effect of these lamps when they are lighted up at night is to make the warehouse more attractive, and to add to its bright and cheerful appearance.

Companies of the Month.—The following electrical companies were registered during the past month:

Akester Electric Syndicate, Limited, £50 shares	£15,000
Dominion Electrical Company, Limited, £5 and 3s. shares	25,125
Elieson Accumulator (British Patent) Syndicate, Limited, £1 shares	12,000
Julius Sax and Co., Limited, £10 shares	20,000
New British Electric Installation Contractors, Limited, £5 shares	25,000
Unity Electroplating Company, Limited, £5 shares	5,000
United Electric Tramways, Limited, £5 shares	30,000

Eastbourne.—The Board of Trade have forwarded to the East Sussex County Council a copy of some correspondence which had passed between them and the Eastbourne Electric Light Company, in reference to the audit of the accounts of the latter body. The Board of Trade had pointed out that the accounts which they had sent in had not been audited by such competent and disinterested persons as the County Council should from time to time appoint. The company, in reply, gave the names of an eminent London firm of chartered accountants, who acted as their auditors, and said probably the County Council was quite satisfied with their audit. The correspondence was referred to the Finance and General Purposes Committee.

Belfast.—A movement of protest has been initiated in Belfast against the proposed encroachment on Ormeau Park for the purposes of the extension of the gas works premises. The fact of the gas works extending into the park would, it is urged, spoil its advantages to the citizens. The Corporation is moving steadily with the work of preparation for the electric lighting of the city, and it is proposed, as already announced, to supply power for 10,000 for the present, the proposal made to provide for 50,000 lights being defeated. The objectors to the encroachment on the Ormeau Park ask for the abandonment of the addition to the gas works, in view of the expected introduction of the electric light, but the Corporation reply that the increased consumption of gas for domestic cookery and the driving of machinery renders necessary an extension of the works.

Western and Brazilian Telegraph Company, Limited.—The report of the Directors for the half-year ended June 30th, 1892, states that the total earnings amount to £84,022, a decrease of £20,941, and the working expenses to £39,141, an increase of £502. Including the amount brought forward from 1891, the balance to the credit of the revenue account is £49,368, from which has to be deducted debenture interest, and a sum for the debenture redemption fund, leaving £30,268, of which £14,000 has been placed to the reserve fund. This leaves £16,268. The Directors recommend the payment of a dividend of 3s. per share, free of income tax, on the ordinary shares for the half-year, being at the rate of £2 per cent. per annum, carrying forward £1,662. The shareholders will note that the falling off in the dividend is mainly attributable to the heavy loss on exchange, which for the period of which the accounts treat averaged 11¼d per milreis, as against 18d. for the corresponding period of 1891. The receipts of the Company for the past week, after deducting 17 per cent. payable to the London Platino-Brazilian Company, were £2,834

Electric Pumps.—The Corlett Electrical Engineering Company, Limited, of Wigan, have recently turned out a very neat form of electric pump with motor on one base-plate, to the order of the Astley and Tyldesley Coal and Salt Company. It is designed for delivering some 40 gallons of water per minute against a head of 300ft. through about 800 yards of 3in. pipes. The pump is of the three-throw type, each ram being 3¼in. in diameter, with a stroke of 5in. A Crompton motor of 5 h p. is used, the Corlett Company being agents for Messrs. Crompton. It is series wound, taking 450 volts 10 amperes for 1,200 revolutions. The motor is geared, in the ratio of 36 to 1, to the pump by gunmetal helical gearing, the speed of the pump being 33 per minute. All bearings are of ample strength, with lubrication for continuous running. The pump is placed half a mile from the bottom of the pit, and the current is supplied from existing lighting plant at the surface. The conductors are insulated solid copper wires, run in wood casing or on earthenware insulators. A second plant will shortly be put in, when a separate generator will be also installed to supply both pumping plants.

Sunderland.—The Highways Committee of the Sunderland Town Council have received a report from the borough engineer on the subject of the application of the National Telephone Company for leave to place underground wires with chambers under the streets for testing purposes The borough engineer said that if the chambers were placed under the footpath they would interfere with many private cellars, and in all probability also with future arrangements for the electric lighting wires being laid. If placed under the carriageway they would interfere with about a mile and a half of wood pavement and break up the concrete foundation for that pavement. The chambers were 7ft. deep and about 7ft. square on the surface, and there would be some 37 of them altogether. The road would have to be carried on iron girders. Mr. Routhwaite further stated that, considering the serious nature of application, he had asked Mr Clay how many poles the proposal would do away with, and when the company would be prepared to carry out the work, and the only reply he had received was that Mr. Clay could not tell. The whole subject was referred to the Electric Lighting Sub-Committee to ascertain if anything of the kind had been done in other towns, and also to press for an answer to the questions raised.

Commissioners of Sewers.—The Streets Committee of the Commissioners of Sewers presented a report at the meeting on Tuesday containing a paragraph relative to the memorial from inhabitants of Ludgate-hill asking that the notice served for removal of sign with electric lamps attached at 37, Ludgate-hill, might not be enforced. The committee stated that, having viewed the same, they could only recommend that proceedings be taken for the removal of the said sign as an annoyance within the terms of the City of London Sewers Act, 1848. Mr. J. C. Bell moved that the report be referred back for reconsideration. Mr. Myers seconded. A discussion ensued, in the course of which Mr. Johnson declared that this was an insidious attempt to set aside the laws of the Commission for the benefit of people interested. He believed that if they allowed this application they would have many more in a very short time. The amendment was lost on a show of hands, and the report of the committee approved. The Streets Committee also submitted a letter from the City of London Electric Lighting Company relative to the progress made in supplying private consumers, and recommended that the company be urged to expedite the matter as much as possible. This was agreed to. The consideration of an application from the City of London Electric Light Company with respect to sites for converter stations was adjourned until the next meeting.

Brighton.—The last meeting of the municipal year of the Brighton Town Council was held last week, when the most important matter for discussion was a proposal of the Electric Lighting Committee to extend the Corporation area of supply so as to embrace about two-thirds of the town. Objectors to the scheme urged that the adoption of the proposal would lead to an enormous outlay, and that there was no justification for entering upon this until the Council had been placed in possession of the financial result of the trading in the present area. Alderman Moon, chairman of the Electric Lighting Committee, regretted that no full financial statement could be presented until the accounts had been made up to the end of the year, and asserted that although, as expected, there had been loss on the present undertaking, amounting to £300 in the last three months of 1891, £650 in the first six months of this year, and a slight loss in the third quarter, a profit was now being made at the rate of £900 a quarter. The success was far greater than they anticipated. He explained that, although they asked for power to cover two-thirds of the town, they would only supply the light where there was a prospect of doing good business, and stated that they already had many applications. It was pointed out that agreement to the motion would not prevent objection to the estimates for further work later on. The committee's report was adopted by a large majority.

ELECTRICITY SUPPLY AND ELECTRIC MANUFACTURING COMPANIES. COMPILED BY MESSRS. FAITHFUL BEGG AND CO.

SUPPLY COMPANIES.

Name of company.	Registered in present form.	Allotted areas of supply companies.	Capital as at November 1, 1892. Authorised. Total shares and loans.	Authorised. Shares. Number.	Authorised. Shares. Reading.—At the Reading Town Council meeting last week, the minutes of the Electric Lighting Committee were read as follows: "At a meeting of the committee on October 20, the town clerk submitted papers which had been laid before parliamentary agents. He also submitted the observations of parliamentary agents on the subject, and several provisional orders granted to companies by the Board of Trade under the Electric Lighting Acts, and called attention to the provisions contained in such orders upon various points specified in the resolution referring this matter to this committee, and also upon other points upon which it may be necessary to protect the interests of the borough. The borough engineer and Mr. McMullen, electrical engineer, explained their views on the matters relating more especially to the system and mode of supply of electrical energy and the method of charge for such supply. The committee carefully considered the matter, and determined on certain modifications which should be made in the proposed clauses submitted on behalf of the company, and also determined on additional clauses which should be inserted in the provisional order for the protection of the Corporation and consumers of electrical energy, and resolved that the town clerk do forward to the company's solicitors their proposed clauses as amended, and the additional clauses, with an intimation that the committee will be prepared to recommend to the Council to give the requisite consent to the company's application for a provisional order if the clauses, as now amended, are inserted therein." This report was carried unanimously, having been moved by Alderman Monck and seconded by Mr. Stallwood.

Llandudno.—The inhabitants of Llandudno are contemplating the proposal to extend the gas works at a cost of £8,000. Mr. Jas. McMaster, writing to a local newspaper, points out that the town is very favourably situated for utilising the electric light. He says: "I am of opinion that for the outlay of a couple of thousand pounds we could produce and deliver, in the town and streets of Llandudno, electricity sufficient to light the whole place all the night through, at a very small annual cost for maintenance. We have an immense volume of water all the year round, streaming down from Llyn Dulyn to the reservoir, from which the town (and Colwyn Bay and Conway at present) is supplied. My suggestion is that a powerful turbine, to drive the necessary dynamos, should be placed in a favourable position on the stream in suitable premises, and the electricity generated and brought thence to Llandudno by the requisite wires, and the whole of the town lighted therewith summer and winter. The cost will thus be a very low figure, certainly not a figure higher than the present charge upon the rates for gas lighting. Llandudno lighted by electricity in the winter time will be a very much more attractive place for both invalid and healthy visitors seeking health and recreation, than the dismally dark and unattractive town it is at the present time. Let anyone try to imagine the difference in appearance which the promenade and all the other leading thoroughfares would have if lighted by glowing electric lamps from that which they now exhibit under the yellow light of 16-candle gas. The whole of the Great Orme's Head would be standing out in promontories of light and shadow, and would be a continual advertisement of the town to all travellers from Mostyn to Bangor by the railway, and passengers by the Atlantic liners from Point Lynas to Liverpool. The introduction of electricity for lighting purposes in Llandudno would set free the £520 worth of gas now consumed in the public lamps, which may then be sold at a profit for private consumption, and I have no doubt many of our enterprising shopkeepers would hastily avail themselves of the opportunity to illuminate their premises with the electric light, and so set free more gas for other purposes." Llandudno is certainly a town which should early adopt the electric light, and a little private negotiation would perhaps put the matter into practical form.

Plymouth Tramways.—The Plymouth Corporation, having recently acquired the street tramways, called in the opinion of Mr. J. Clifton Robinson, as expert, to value the lines and advise as to their future working. He considers the price paid—£12,500—a moderate one, and advises certain extensions which would measure 1 mile 39 chains, and cost—allowing for the proportion of rolling-stock and equipment—some £15,000. After strongly recommending the erection of a depôt on the piece of Corporation ground adjoining the Technical Schools, Mr. Robinson has proceeded to deal with the future efficiency of the lines. He speaks very decidedly. "I have no hesitation in saying that a far higher measure of efficiency and success would be achieved by the adoption of electric traction. Immense strides have been made in the development and operation of electricity for tramway purposes during the last few years. Indeed, within five years I have seen the installation of electricity as a motive power on more than 300 different lines of tramways in the United States of America, Canada, and the Continent. These lines aggregate over 3,000 miles of tramway and street railway, successfully operated under nearly every known condition of climate, gradient, and city conformation. One important point to be kept in view by the Corporation in considering the proposition to change from horse-power to electricity is that the overhead-wire or trolley system, as recently adopted at Leeds and proposed for adoption in other large cities in the United Kingdom, can alone be regarded. The reason for this is that the introduction of the overhead wires entails little interference with the existing mode of track construction. In order to convert existing lines to this method of traction, it is only necessary to provide what is known as a 'ground return,' which is effected by connecting the lengths of rails at the joints by galvanised iron wire. Track wires are also used connecting at about every 1,000ft. with iron plates sunk in the earth. This arrangement would entail an addition of about **£150 per mile of single track. Support for the overhead wire is**

given by poles of convenient height on each side of the street. Spanning the street is a single wire holding the current wire in position over the centre of the track. Poles, wires, and necessary connections would not exceed £500 per mile. The power station, where electricity is generated by means of steam, gas or water power may be situated near any portion of the line, a central position being preferred. A substantial building amply sufficient for car depôt, workshops, and offices would cost about £5,000. The power plant would consist of two 250 h.p. engines, with boiler of appropriate size, and two dynamos of from 200 h.p. to 225 h.p. The steam power would I estimate cost about £12 per horse-power or £6,000, and the electric plant about £3,600." The carrying out of this scheme would require the provision of 10 electric motor cars at a cost of £600 each. Mr. Robinson estimates the total cost for the electric equipment, including plant, machinery, buildings, cars, etc., at £25,000, giving an entire expenditure on the whole system of £50,000. Against some of this would, of course, have to be set the returns from the sale of the plant and horses, which it is intended to use temporarily, in order that the lines may be worked with as little delay as possible. He thinks that the annual cost of working the electric system would be £7,800, and calculates that the returns would equal 7½ per cent. of the capital outlay of £50,000.

PROVISIONAL PATENTS, 1892.

OCTOBER 31.

19496. **Improvements in and relating to electromagnets and magnetic circuits.** William Lowrie, 117, Bishopsgate-street, London.

19497. **Improvements in electric lamps and in their manufacture.** Hannah Clegg, Brampton, West Norwood.

19543. **Improvements in electric indicating apparatus.** Leicester Bradney Stevens, 40, Chancery-lane, London.

19569. **Improvements in electrical connections.** Osmond Ferguson, 37, Chancery-lane, London.

NOVEMBER 1.

19602. **Improvements in electric switches.** Alexander Bewicke Blackburn, 51, Withington-road, Manchester. (Complete specification.)

19646. **Improvements in the method of supplying electrical energy of required potential to electric current circuits.** William Lowrie, 433, Strand, London.

19655. **Improvements in and relating to a method of and means for heating by electricity.** Henry Gibson O'Neill, 77, Chancery-lane, London. (Complete specification.)

19657. **Improvements in underground conduits for electric cables.** Robert Ewing, 19, Great George-street, Westminster, London.

19665. **Improvements in and relating to telephonic apparatus.** George Septimus Hooker, 27, Martin's-lane, Cannon-street, London.

19671. **Improvements in means for conducting electricity for electric lighting and other purposes.** Martha W. Pollard, 4, South-street, Finsbury, London. (Complete specification.)

NOVEMBER 2.

19690. **Improvements in and connected with the distribution of current in incandescence electric light circuits.** Oscar Axel Enholm, 70, Market-street, Manchester. (Date applied for under Patents Act, 1883, section 103, October 3, 1892, being date of application in United States.) (Complete specification.)

19699. **Improvements in telephonic apparatus.** Daniel Sinclair, 62, St. Vincent-street, Glasgow.

19714. **Improvements in dynamo electric machines.** Henry Chitty, 5, Bolton-gardens, Chiswick, London.

19729. **Improvement in and means or apparatus for rectifying alternating currents for working continuous current motors, and for electrolytical purposes.** Charles Pollak, 33, Chancery-lane, London.

19730. **Improvements in distributing boxes for electric light, and power mains for underground and aerial purposes.** George Joseph Philpott and Amos John Willett, 48, Gloucester-road, Brighton.

19738. **Improvements in portable electric safety lamps and batteries and appliances for charging them.** The Edison and Swan United Electric Light Company, Limited, and Edward Alfred Gunningham, 28, Southampton-buildings, Chancery-lane, London.

19739. **An improved electrical switch.** Edward Lionel Joseph, 115, Cannon-street, London.

19749. **Improvements in the construction of indicating and transmitting instruments for telephones.** Henry Harris, 9, Warwick-court, Gray's-inn, London.

19758. **Improvements in electric conductors.** William Lowrie, 117, Bishopsgate-street, London.

19761. **Improved means for obtaining electricity on board ship.** Howard Ralph Maltby, 37, Chancery-lane, London.

NOVEMBER 3.

19771. **Improvements in and relating to telephonic instruments.** James Muirhead, 96, Buchanan-street, Glasgow.

19821. **Improvements in alternate-current transformers for variable loads.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

19834. **Improvements in and relating to telephonic switching apparatus.** Alfred Roslin Bennett, 45, Southampton-buildings, Chancery-lane, London.

NOVEMBER 4.

19874. **Improvements in means or apparatus for regulating the supply of electrical energy to lamps and other apparatus.** Edward Pindar Davis and Adrian Charles Collins, 55, Chancery-lane, London.

19880. **The manufacture or production of an improved anode for use in electrolytical processes.** Thomas Parker and Alfred Edward Robinson, 47, Lincoln's-inn-fields, London.

19881. **Apparatus for controlling electric pressure in alternating-current circuits.** P. Walter d'Alton and John Ambrose Fleming, 28, Southampton-buildings, Chancery-lane, London.

19886. **Improvements in making house connections with electric lighting mains.** William Fuller, 24, Southampton-buildings, Chancery-lane, London.

19889. **An improved electric clock.** Adolph Edward Vela and Gaston Hervieu, 9, Warwick-court, Gray's-inn, London.

NOVEMBER 5.

19910. **Improvements in reflectors for electric and other lamps and lights.** Percy Gartner Ebbutt and John Benjamin Verity, 128, Colmore-row, Birmingham.

19916. **Improvements in electrical conductors, and in means of making connection therewith.** Claude Theodore James Vautin, 1, Queen Victoria-street, London.

19919. **Electric light conductors.** George F. de Solome, 17, Hanover-street, Islington, London.

19927. **Improved means for lighting railway cars by electricity.** Johannes Kerner, 6, Lord-street, Liverpool. (Complete specification.)

19953. **Improvements relating to the construction of electrodes for electrolytic purposes.** James Charles Richardson, 6, Bream's-buildings, Chancery-lane, London.

19959. **Improvements in the means or apparatus for measuring electricity.** Edward Howard Percy Humphreys and William Friese Greene, 55, Chancery-lane, London.

19960. **Improvements in ammeters and voltmeters.** Edward Howard Percy Humphreys and William Friese Greene, 55, Chancery-lane, London.

NOTES.

Carbons.—A new arc carbon factory is being erected at Paris.

Japan is to have a cable-laying steamer for native engineers.

Lyons is shortly to have an overhead conductor system of electric traction.

Quebec. — An overhead electric railway is being organised in Quebec.

Brussels.—Steps are being taken, says the *Financial News*, with a view to laying another electric tramway at Brussels.

Electro-chemistry.—It is stated that one of the largest banks in Paris is taking up the question of electro-chemistry.

Accident.—Sir M. Morrier-Williams has had his right forearm slightly fractured in Switzerland by a fall from an electric car.

Extension.—The New York *Electrical Engineer* has moved into new and handsome extensive premises at 203, Broadway, New York.

Belgian Railways.—The authorities of the Belgian State railways have decided to carry out experiments with electrical traction at Liège.

Brest.—Besides three engines by MM. Weyher and Richemond, the fort of Brest will have in its installation five engines by MM. Sautter, Harlé, and Co., who will also furnish all the electrical plant for the installation.

Industrial Electricity.—M. Marcel Deprez is giving a course of lectures at the Conservatoire des Arts et Métiers, at Paris, on industrial electricity, more particularly from the point of view of electric transmission of power.

Electric Photography.—Mr. F. J. Smith read a paper on "Photography" before the Oxford Junior Scientific Club, dealing with the question of taking photographs of extremely short duration of exposure by electric spark.

Electric Heaters.—The electric heating business is becoming an important industry in Canada. A number of Ottawa capitalists have recently formed a company to work the Ahearn patents for electric heaters, ranges, and ovens.

Electric Drying-House.—A drying-house for timber is nearly completed by Mr. Parr, at the Caudere, Ottawa, Canada. It will be heated by electrical apparatus, and will be the first building in existence for drying timber electrically.

The First Electrolier.—The huge and elaborate electrolier constructed by Messrs. Verity for Edison's exhibit in 1881, is being offered to the American electrical engineers as suitable for exhibit at Chicago as "the first electrolier" ever made.

Electricity at the Coalfields.—A paper was read last Saturday before the Manchester Association of Engineers by Mr. B. H. Thwaite, on "Economic Possibilities of the Generation of Electromotive Force in the Coalfields and its Application in Industrial Centres."

Oxford.—The electric light, adopted wholly at Brasenose College and Hertford College, and partially at some other colleges, is voted a great success, although there is some difference of opinion as to its suitableness for reading purposes. Perhaps there is need of more frosted lamps.

Central Stations.—A special course of six lectures will be delivered before the Society of Arts, under the Howard Bequest, on Friday evenings, commencing January 13, 1893, by Prof. W. Cawthorne Unwin, F.R.S., on "The Development and Transmission of Power from Central Stations."

Ward Arc Lamps.—The Ward Arc Lamp Company are now making a twin arc lamp, having two sets of carbons taking five amperes to burn direct on a 110-volt circuit. This lamp gives an equivalent in light of a 10-ampere lamp, and is useful where a customer only requires one lamp. The ordinary Ward arc lamps are being made at the rate of 400 a week.

Country Machinery.—If contractors, wishing to obtain country mansion practice, were to supply as a regular article an engine that would act as a fire-engine pump, and would also pump water, drive a chaff-cutter, a cream separator, and a circular saw, with a dynamo for electric light thrown in, they would get more orders for electric lighting than they now procure.

South Kensington Electric Railway.—It is stated that it is intended to proceed next session with the Bill for the construction of an underground electric railway from Paddington to South Kensington, the scheme having been altered to meet the objections of the opponents of the line, which it is proposed to extend to Clapham Junction, passing under the Thames.

Firth College Popular Lectures.—On Saturday evening, at Firth College, the first of a series of lectures on "The Electric Current" was given before a numerous and appreciative audience by Mr. R. Lehfeldt, a member of the professional staff of the college. The lecture, which was to a large extent introductory, was illustrated by numerous interesting experiments, and repeatedly applauded.

Westinghouse.—Rumours are freely circulating that within a month the Westinghouse will become part of the American General Electric Company. This statement will probably require a denial to follow. It is more likely that a reciprocal arrangement will be come to that the General Electric may use the new Westinghouse lamp on condition that all litigation against Westinghouse be withdrawn.

Chicago Exhibition.—It will scarcely be believed in this country that the ridiculous determination is said to have been made by the Chicago authorities that the gates of the exhibition shall be closed at seven o'clock in the evenings of all ordinary days. It is hardly likely this idea can be held for long. What on earth would the electric lights be for if the fair is to be an early closing association?

Siemens Electrodynamometer.—Messrs. Siemens and Halske have introduced, we see it stated, a modification of their well-known electrodynamometer to prevent a magnet in the neighbourhood affecting the coils carrying the current. The single solenoid is replaced by several arranged around the same axis, so that they are repelled to the same extent that they are attracted by any neighbouring magnet.

Circulating Battery. — M. Serrin has recently brought out a continuous circulating battery, illustrated in *L'Electricien*, which is a simple sulphate of copper battery with zinc and carbon electrodes, but with a syphon arrangement for keeping up a continuous circulation. Two vessels, from and to which the liquid flows, are reversed every morning. The battery, it is claimed, has a low internal resistance, and is constant and economical.

Electric Railways and Telephone Companies.—A case has just been decided by the New York Court of Appeal on the respective rights of electric railways and telephone companies to earth. The Court decided that the telephone company could no more justly complain of its loss from grounded currents than it could, if by jarring

of loaded vehicles in the street, its delicate and sensitive instruments were impaired or destroyed. The railroad company was given costs.

Municipal Telephones for London.—Mr. Barrs placed the following motion on the paper of business for the meeting of the London County Council: "That it be referred to the General Purposes Committee to consider and report whether the Council has power to establish and work a telephonic system in London similar to the system established and worked by the municipalities of Christiania, Liverpool, Manchester, and other towns, and if so, to consider and report as to the desirability of exercising such powers."

Fire in Regent-street.—On Wednesday afternoon the firemen at the West-end stations were called to a shop alight in Regent-street, and it was found that the premises of the London Stereoscopic and Photographic Company, at 106 and 108, Regent-street, were in flames. In his official report Captain Simonds states that the cause of the fire was "overheat of electric wires," which had set fire to the shop window and its contents. Deliveries from a hydrant were sufficient to subdue the flames, but the house and shop suffered by smoke and water.

Appointment.—Mr. H. F. Lewis, who has for many years been general manager and secretary of the Western Counties and South Wales Telephone Company, now absorbed by the National Telephone Company, has retired from the post he has hitherto occupied, and has accepted the important position of general manager to the London Electric Supply Corporation. The immense energy and long experience of Mr. Lewis in connection with electrical and telephonic matters will doubtless prove of great value to the company with which he has now associated himself.

Electrical Imagery.—There is an extraordinary "electrical group," by Mr. Outcault, illustrated in the *Electrical World*, as intended for the transportation building at Chicago, which, if a fair specimen of the decoration intended for the exhibition, does not say much for the designing power of American sculptors. Semi-draped, awkward figures all out of drawing, even if trampling on Gramme rings and poising huge telegraph tappers, do not make an electrical group; and when one weak-kneed damsel is seen holding a field magnet of ½cwt.—though her arms are as stout as a fish-wife's—the absurdity and crudity of the design are manifest. The most fanciful of all sciences can surely furnish better imagery than this.

Presentation to the New Telephone Company's Manager.—The employés of the New Telephone Company met at the company's Manchester offices on Monday evening, and presented Mr. G. J. Somerville with a silver tea service on the occasion of his leaving Lancashire, where he has been manager since the opening of the exchange early last year, to take charge of the company's metropolitan district. In making the presentation Mr. W. A. Valentine referred to the esteem in which Mr. Somerville was held by all the employés of the company, and said that the great progress of the exchanges in the Lancashire district was in a large measure due to his untiring energy. Mr. W. A. Valentine has been appointed district manager of Lancashire.

Canada and Imperial Telegraphs.—At a meeting of the Ingersoll (Ont.) Board of Trade last month, the following resolution relating to the extension of direct telegraphic communication throughout the Empire was passed: "That this Board concur in the suggestion that the extension of the telegraph system to all parts of the British Empire is well worthy of grave consideration, and that a commission appointed by the British Government would be the best and most practical means of calling attention to the scheme, elicit information, and suggest a feasible plan for accomplishing such a desirable and far reaching result, and which would have the effect, in the opinion of this Board, of stimulating the trade and commerce of the Empire."

Limits to Telephony.—Messrs. Bedell and Crehore, in a paper on the effects of self-induction and distributed static capacity in a conductor, come to the conclusion that the difference in the rates of propagation and decay of waves of high and low frequency doubtless constitutes the limitations to the use of the telephone. As the several harmonic components of a complex tone advance along the conductor, they keep shifting their relative phases according to the difference in their rates of propagation, and also change their relative intensities according to the difference in their rates of decay, thus changing the resultant combination tone and materially altering its quality. These effects are always present in circuits containing distributed static capacity, but are not so marked when there is no self-induction.

Canterbury Cathedral.—The authorities of the Canterbury Cathedral have recently entered into a contract with the gas company to be supplied with gas from the works and have abolished their own plant. This decision is regarded with much disfavour in the city, as the deleterious effect of the deposited carbon is very noticeable in cathedrals and churches, and it is thought every effort should be made to introduce the electric light. The late architect was in favour of that step long ago, but at that time the expense was too great. The present consulting architect should be approached with the idea of introducing the more cleanly light into one of our loveliest monuments of Gothic art. If the consent of the authorities can be obtained by the proposed Canterbury and Dover Electric Company, a desirable customer would be secured and a national treasure would be safeguarded.

Telegraphic Rates to the Antipodes.—A conference of Australasian Agents General was held on Tuesday at the Colonial Office with the Marquis of Ripon on the subject of cable rates to the colonies. The Earl of Kimberley was present at the conference, as representing India, and Sir John Pender, M.P., representing the Eastern Telegraph Company. All the agents-general, except the representative of Queensland, were present, with the object of pleading on behalf of their respective Governments against a proposed increase by the Indian Government of 1½ centimes a word for the transit of cable messages to the Antipodes by way of the Indian lines. It was pointed out that before a decisive answer could be given the Indian Government would have to be communicated with, but in every other respect Lord Ripon accepted the request of the Australian colonies. The result of the conference was regarded as most satisfactory by all persons concerned.

Another Remedy.—We commend to our esteemed contemporary the *Electrical Review* the perusal of a little pamphlet which is being scattered broadcast in our [illegible]. Its title is "The New Remedy—the Electropoise," and, according to its author, this new remedy "will make you master of disease," "will cure you of whatever your complaint may be; no matter what its character, the electropoise will cure you of it." Of course, to assist to force this remedy into public favour, there is the usual Press notices and report from a so-called expert. The notices we have before us are from the *Woman's Herald*, and from the *British Journal of Commerce*, *Brighton Standard*, *Birmingham Chronicle*, and the *Weekly Star*. The expert is Peter Auchinachie, Ph.C. (What does Ph.C. mean—Pharmaceutical Chemist?) If so, this is no title, and falls under Prof. Tilden's anathema. We wonder how many will

misread it Ph.D. We do not hesitate to denounce this pamphlet as a tissue of lies, and that no remedy whatsoever, even though compounded of the word "electro" or "electric," has any such effect as is claimed herein.

High-Speed Railway in Austria.—An interesting lecture, which has caused a good deal of comment in the newspapers, was delivered on Saturday, in Vienna, at the Society of Austrian Engineers and Architects, by one of the members (M. Hugo Kostler). The subject was the proposed electric railway for rapid communication between Vienna and Budapest. According to this project, an electric railway would run on the right bank of the Danube at the high speed of 200 kilometres, or 120 miles, an hour, thus reducing the journey between the two capitals from five hours to one hour and a half. The distance between Vienna and Paris, which is now covered in 26 hours, would then only require seven hours, and that between Paris and Constantinople would only take 15 hours instead of 65. The trains would have a single carriage, containing 40 passengers, and could be despatched at intervals of 10 minutes. The differences of grade being taken into account, an electric motor of 200 h.p. would be necessary for each carriage. It is stated that arrangements are being made to test this system between two important centres.

Electric Mine Lamps.—At the general meeting of the South Wales Institute of Engineers, held on Tuesday at Cardiff, Mr. Theodor Raaschon introduced the "Bristol" miners' el ectric safety lamp, and Mr. J. P. Rees an electric safety lamp of another kind. Mr. G. W. Wilkinson (Risca), who had h ad a good deal of practical experience of the use of electric lam ps underground, was asked for his views, and said he had not found them entirely successful as yet. They went all very well for the first three or four months, and then the acids saturated the structure of the lamp, and rendered it practically useless. A gentleman from Lancashire related a similar experience. Mr. Raaschon offered to supply 500 of his solid brass-cased lamps, and if they did not stand a fair test for 12 months at least, the makers would bear the loss. Mr. Bailey agreed to accept the offer. Mr. Wilkinson also offered to give them a fair trial. The president observed that it was most essential that a fair test of the lamps should be made, as if they got a thoroughly sound self-contained electric lamp they would go a long way to ensure safety in the mines.

Newspaper Offices.—A description—with a note of interrogation—is thus given in a recent number of *Lippincott's*, by Mr. J. A. Cockerill, of the offices of the *Chicago Herald*: "What would an *ante bellum* journalist say to a business office with 3,600ft. of floor space flanked by 16 columns of genuine Sienna marble? What would the old-time 'typo' think of a composing-room with its walls of white enamel, its quadruple cast-iron type stand, with cases for 180 men, its electric calls connecting each case with the copy-box, its aerial railway conveying advertising matter up to the business offices, its separate clothes closets for 160 men, its extensive reference library for the use of the proofroom, its marble closets, filtered ice-water coolers, with solid silver gold-lined drinking-cups, its 348 incandescent electric lights and marble-topped lunch counters and tables? What would have been thought of marble bath-tubs for the stereotypers? Of a great central library for the editors and reporters, around which are arranged a score of handsome editorial rooms? What would the old-time journalist say to a publisher's apartments in which all the metal fixtures are oxidis d silver, and all the woodwork solid mahogany; of marble clothes closets, and bathrooms for all employés, and a constant flow of cold clear water day and night from an unfailing artesian well?" Luxurious journalism, this!

Age-Coating of Incandescent Lamps.—Prof. Edward L. Nichols has an article on the age-coating, as he terms it, of carbon in the incandescent lamp, which is given in the *Electrical World*. A number of experiments, which are tabulated, show that the decrease in the relative transparency of the globe is only partly responsible for the decline in light of lamps. After 800 hours, in one case, the relative brightness was only 45 per cent. of the original—the relative efficiency being 51·3 per cent. and the relative transparency of bulb 78·24 per cent. The results are thus summarised: 1. The rate of deposit of the coating in incandescent lamp bulbs is greatest in the early part of the life of the lamp. For example, in the case of a lamp which lasted 800 hours, more than half the coating was deposited during the first 200 hours. 2. The loss of brightness due to the absorbing power of the age-coating is a variable part of the total loss, being greatest in lamps of high initial efficiency. 3. The coating does not appreciably modify the character of that light which emanates from the lamp. 4. The distribution of the coating within the bulb is nearly uniform. 5. No marked difference between heated and unheated filaments appears to exist as regards the density of quality of coating produced from them. Since the writing of this article it has been pointed out by Prof. B. F. Thomas, that in the case of lamps exhausted without the aid of mercury the age-coating is scarcely perceptible.

Double-Decked Railways.—A long and statistical article upon rapid transit takes an important place in the last number of the *Quarterly Examiner*, to which those specially interested in the question might refer. The question of electrical railways naturally occupies a considerable portion of the article, and some views of rather a novel kind are promulgated. The necessity for two kinds of passenger traffic—high speed for long distances and more moderate speeds for suburbs—has led to the suggestion of double-decked railways for London, where sites are so valuable that doubling the width means an enormous expense. Take, for instance, the Cannon-street and Waterloo line. This used to serve for a "shuttle service" of trains between the City and West-end, but has long since been utilised also for main passenger traffic. Why not, it is suggested, surmount the present line with another lighter railway driven by electricity, and so regain for the South-Eastern much of the traffic it has lost? The suggestion is expanded to the proposal to run double-decked railways, the lower or ground floor for high-speed heavy trains, and the upper floor for light single-car electric carriages for shorter distances. It is not all railways which, like the Waterloo line, could erect a superstructure, for tunnels would interfere, but as an alternative for the costly device of underground tunnelling it might serve in certain cases. The real value of the *Quarterly* article is to show that the attention of those in authority is rapidly becoming attracted seriously to electrical railway undertakings, and the proposals which now abound, amongst others that of a high-speed railway for Vienna, mentioned elsewhere, equally indicate that large and important enterprises may soon be undertaken.

Gilding Grids.—The *Electrical World*, commenting upon our announcement of Mr. FitzGerald's discovery of the efficacy of using gilded lead grids for accumulators, has the following editorial note: "Most of the alleged improvements in accumulators deals with the shape and form of the grids to prevent the active material from falling out. But in experiments made in England by Mr. D. FitzGerald, who has done very creditable work in the accumulator field, he attacks the problem in a different way, and, if reports are correct, he has been more successful than those

who try by changing the shape of the holes in the grids to keep the material on them. He goes back a little farther and tries to prevent the layers of sulphate between the active material and the lead surface to which it is held; for it is the layer of sulphate forming, as is well known, on the discharge which is at the root of much of the evil. His experiments seem to show that by gilding the lead plates of the grids, even only quite lightly, the formation of this sulphate is prevented. If such gilding does not develop new and unforeseen difficulties, as most new inventions in accumulators do, it may prove to be one of the most important in the recent development of this much abused apparatus—the lead accumulator." In Mr. FitzGerald's experiments no such difficulties as are above mentioned have as yet manifested themselves, and we are somewhat surprised that this really important invention of Mr. FitzGerald's has not created more outward interest. There are, perhaps, several reasons for this. Some accumulator manufacturers do not require lead grids at all. The greatest manufacturers—the Electrical Power Storage Company—from a business point of view, would seem to favour cheapness rather than extreme efficiency. Something might be done if its cost and the possible deleterious action of chlorine on the gold is not found to stand in its way. We trust this improvement will be well tested by independent parties, and not allowed to become lost to sight.

Cost of Electric Light.—Mr. Arthur B. Gill writes an interesting letter to the *Journal of Gas Lighting* with reference to the cost of electric light as compared with gas. His letter was drawn forth by remarks upon the installation at the National Safe Deposit Company, for which he was contractor. The current here is obtained from dynamos driven off countershaft from the engine which drives the fan and pumps. There are 120 lights of 16 c.p., but only 30 in summer and 45 in winter are used at a time, or an average of two units per hour. "There is no doubt," says Mr. Gill, "that the electric light has cost less than gas for the year 1892, as compared with 1891, in which year the company adopted the Welsbach burners, which effected a saving of 45 per cent. over previous years. An interesting point is that, whereas the fans were driven to ventilate and drive out the products of combustion from the burnt gas (the premises being all underground), they have been almost dispensed with. The power they used to absorb is now given to the dynamo; therefore, the light is produced by the power that was formerly practically wasted in ventilating—the net result being that the consumption of coke, which in 1891 came to £76, was reduced in 1892 to £74. (I admit that coke was cheaper in 1892.) The actual quantity used for producing the light amounted to less than £20. Of course, interest and depreciation have to be added to this, as also a slight increase in wages, which was given to the men to get them to take an interest in the plant. I may say that the wear and tear was inappreciable, and the repairs were nil, as they should be in an installation which is erected in a proper manner, and when the price is not cut down, as is unfortunately the case in most installations." He adds that he produces the electric light at his own house with a gas engine for 1.5d. per unit = 16 lamps of 16 c.p. per hour, which means a consumption of 50 cubic feet per hour, or less than 2d., including oil (gas being 2s. 6d. per 1,000 cubic feet). This speaks for itself, he thinks, as to whether or not large consumers should produce their own current.

Asbestos.—Mr. J. Alfred Fisher, general manager of the United Asbestos Company, has forwarded to us a copy of *an interesting paper* read by him before the Institute of Marine Engineers on "The Mining, Manufacture, and Uses of Asbestos." The paper was illustrated by specimens of asbestos from various countries, both raw and manufactured. It appears that discoveries of this material, so useful to the engineer, are being constantly made, but except from the Canadian and Italian beds the specimens are practically useless for manufacture. Mr. Fisher describes the district in the Susa Valley, Piedmont, where the floss and powder asbestos are obtained, throwing in a romantic touch of history. The second district, about 30 miles long, is in the Aosta Valley, where the deposits are said to be almost inexhaustible. There is a third district, still more important, at Valtellina, the route to which passes Milan and Como to Colico. The Canadian deposits are at a district called Black Lake, between Quebec and Sherbrook. The asbestos-bearing rock is usually some kind of a green serpentine, and in working is first crushed in special machines so as not to destroy the fibre. The long fibre is shaken, carded, and spun, much like cotton and wool, into yarns, tapes, and cloths. In the rubber department it is proofed and made into sheeting, tapes, and rings for steam and other joints, or into cloth and millboard.. A special kind of packing for high pressure cylinders, known as "Victor" metallic cloth, is made by weaving together brass wire and asbestos, and is used in many marine engines. At the company's works at Harefield processes are adopted for utilising every part of the fibre—the shorter lengths being made into millboard, and the fluff and powder into non-conducting composition. The subject of covering steam boilers and pipes has been brought into special prominence by the rule of the Board of Trade that all steam pipes and boilers shall be tested by hydraulic pressure to double the working pressure at stated intervals, the lagging being first removed. This necessitates removable coverings, and non-conducting asbestos mattresses are now made, weighing only 1½lb. to the square foot, removable without trouble. Mr. Fisher points out the numerous other uses for asbestos—the fire-resisting paint for exposed woodwork, funnel paint, asbestos bunker baffle plates to keep off the heat from coal bunkers, and numerous other purposes. The paper is a valuable epitome of the history of asbestos.

Engineering Experience.—As soon as the large number of earnest students who attend the technical college classes achieve their desire—pass through the course and the examinations—they are cast off into the world to shift more or less for themselves. Then comes the great problem what to do to gain experience. Two ways are open to them. One is to seek for some position, no matter much what, that they can obtain without, or preferably with, payment; and the other is courageously to plunge a third time into the bonds of pupilage, and—after already having learnt the three R's and then the "C equals E over R," and the rest—turn to and learn engineering, paying a premium higher or lower, according to the requirements and the purses of the parties concerned. Who to go to? Where to seek? These are then the problems. The first-rate electrical engineers are few, and the pupils they require for premium are many. The fortunate scholar needs to be born with a rich father or uncle in the background to enter here, and then perhaps he is one of half a hundred with scant prospect of learning real engineering design. The spread of electrical science into nearly every branch of engineering might lead intending pupils to go further afield in their quest for experience than hitherto has been deemed advisable. A large number of engineering firms are now starting an electrical side, and with them the students, full of electrical lore and with the power of

testing instruments and dynamos, might really be of service at once, and, besides, would be where full knowledge of engineering method and design can be acquired. The great engineering works of Lincoln, Grantham, Newcastle, Lambeth, and Erith have now their electrical branches as a matter of course, and if the students who wish experience were to bombard the many larger engineering firms rather than overwhelm the few well-known electrical engineers, it might be better for them, both at once and in after life, for the extended experience would lead to that possibility of opening up new branches of application in which the hope of the coming generation of electrical engineers consists. There is also that wide field hinted at by Mr. FitzGerald—the chemists—who already are widely using electricity in manufacturing processes, and the outlook here is not less promising. Further, there are the railway engineers proper. When electricity promises more and more to revolutionise the rapid transit of town and country alike, those men will be most in demand for this work who, trained in electrical schools, have mastered ordinary railway practice, and are capable of carrying to a successful issue the superintendence of the numerous traction schemes that are looming ahead.

Coast Communication in Cornwall.—A great deal of work has been carried out during the past few months in connection with a scheme for coast communication in West Cornwall. Operations were commenced in June last, when the coastguard station at Porthleven was connected by telephone with the Lizard signal station, a distance of 14 miles. From the signal station a wire is carried direct to the house of the chief officer of coastguard, two miles off. There is also a wire from the Lizard station to the Cadgwith Post Office, three miles distant, also having communication with the Cadgwith Coastguard, 300 yards away. From Cadgwith is a wire connecting Coverack, Porthoustock, Porthallow, and St. Anthony-in-Meneage. This communication is *viâ* St. Keverne and Manaccan. Although Manaccan is only a mile across the river from Helford, where there is a coastguard station, it is not at present contemplated to carry the telephone to that station. Nor will a wire connect Helford with Maenporth. There will, however, be communication between Maenporth and Falmouth, but it is regarded as a serious oversight not to connect Manaccan, Helford, and Maenporth, because should a wreck occur anywhere in the Helford river, as has more than once happened, the nearest telephone stations would be St. Anthony-in-Meneage, about two and a half miles distant, and Maenporth, four miles away, whilst the nearest lifeboats which could be summoned would be those at Falmouth and Porthoustock, a wire being laid between these places by way of King Harry Passage. Up to the present, St. Mawes and St. Anthony-in-Roseland are not telephonically connected, but, doubtless, will be in time. During the winter communication will be made between Porthscatho and Caerhayes, the circuit to include Carne and Portloe. Then there will be a circuit connecting Caerhayes, the Greeb, the Dodman, Gorran Haven, and Mevagissey. It is anticipated that this portion of the work will be completed by March. Last week the islands of Scilly were telephonically connected — Tresco, Bryer, St. Martins, St. Marys, and St. Agnes—and this circuit was "spoken" round for the first time on Friday. The work proposed to be carried out next year includes the connection of the following circuits: Fowey to Mevagissey and Fowey to Polperro; Prussia Cove to Marazion, Penzance, and Mousehole; Penberth to Sennen, Porthleden (St. Just), and Pendeen Coves; Trereen Cove (Gurnard's Head) to St. Ives and Hayle; Hayle to Gwithian and Portreath; Portreath to Porthtowan, St. Agnes, Perranporth, and Newquay. It is believed that all the lighthouses around the coast, including the Wolf, Longships, Seven Stones lightship, St. Anthony, Godrevy, Bishops, and St. Agnes will ere long be connected with the circuits mentioned.

Electric Tell-Tale for Coast Defence.—The Portsmouth correspondent of the *Times* describes an ingenious electrical and telephonic apparatus for defending roadsteads, anchorages, and mine-fields by giving warning by visible and audible signals on shore of the approach at night, or during thick weather, of torpedo boats or other hostile vessels, which has just been subjected to experiments extending over several weeks. These experiments were carried out at the mining establishment in Stokes Bay, where the apparatus was witnessed in operation by Colonel Vetch, of the War Department, a committee of Royal Engineers from Chatham, and various officers belonging to the "Vernon." The instrument is called a hydrophone, and its inventor is Captain M'Evoy, the well-known torpedo and submarine mining expert, formerly attached to the Confederate Army. The hydrophone consists of two parts. One part is placed at the bottom of the water outside the anchorage or mine-field at a depth of from five to fifteen fathoms, and the other is fixed on a station on the shore, and the two are electrically connected by cable at distances of from one to five miles. In the present instance the instrument was sunk in seven fathoms, and about 300 yards off Fort Gilkicker. The submerged part consists of a bell-shaped iron case, ⅜in. thick, 20in. in height and extreme diameter, and weighing about 340lb. At the top is fitted a sensitive vibrator or diaphragm enclosed in a copper box. It is formed of a plate of ebonite with carbon attachments, and when the case is submerged the delicate mechanism is kept clear of the water by means of the column of compressed air, which is enclosed as in a diving-bell. No sooner does a torpedo boat approach within a radius of half a mile, or a man-of-war within a mile, than the pulsations of her propellers produce a vibratory movement inside the case. These vibrations are transmitted to the station on shore in the following manner: The electric current from the land battery passes through the vibrating mechanism and also through the apparatus on the shore, in the circuit of which is placed an instrument named a kinesiscope, which is somewhat of the nature of the galvanometer. By means of this the perturbations in the water are communicated to a needle flickering in a graduated arc, and when the oscillations become pronounced the needle is clutched by a magnet at the end of the arc. Contact is thus made, and the vibrations in the submerged case are made visible and audible by means of flashing lights, the firing of a gun, and the ringing of a bell. Telephonic signals are also transmitted through the same current. The whole of these operations were successfully performed in the presence of the visitors. The idea is that for coast defence a number of hydrophones should be sunk in the approaches to a port or dockyard and connected with a central station, and that, as soon as one of them has given its warning of the neighbourhood of an enemy, the information should be communicated to the threatened point by independent cables. It is contended, also, that another field of operations is open to hydrophones in dangerous zones around certain well-known headlands that are frequently fatal to shipping in dense fogs. Captain M'Evoy would connect a danger zone by means of hydrophones with the nearest coastguard stations. By these means a ship would be warned of the danger it was in by the automatic firing of a gun or flashing of a light.

THE SOUTH STAFFORDSHIRE TRAMWAYS.

In describing the South Staffordshire Tramway Company's electrical equipment—just completed over a considerable portion of their line—it is hardly possible to commence by saying that here we have the first steps taken by a system of passenger transit to improve its previously existing methods, and adopt the very newest and latest ideas that have been developed in any country, with a view to greater economy and efficiency.

So far as concerns the fundamental principle that underlies the new electric tramway, it has, of course, been shown in successful operation for some time in this country already, since, indeed, the short length of line at Leeds was equipped on the overhead conductor system, operating continuously thereafter to the present time, with satisfaction to the local authorities and the public.

Nor, so far as concerns electric traction in its broadest applications, can it be said that English people are ignorant of its possibilities or actualities. There are already ten or a dozen lines of railroad or tramway type, either projected or in active operation for the transit of passengers, and the interest aroused by these amongst the general public has been both widespread and deep.

In spite, however, of what has been done in this direction during the past few years, and taking into full account the enormously rapid progress and development of electric traction in the United States, it may be stated with much confidence that the system just inaugurated upon the South Staffordshire tramways will take a most prominent—if not the leading position amongst electric lines, by reason more especially of the improvements and advances that have been effected in its essential details.

It is not to be concluded from this statement—which will, doubtless, receive confirmation at the hands of electrical engineers generally—that previous appliances or methods have proved insufficient or unreliable, nor yet that the new system just introduced is essentially perfect. Even the contractors themselves admit that the stress of daily wear and tear must develop weak points into active faults, but there is also no doubt that the same ingenuity which has overcome so many serious obstacles in this connection may very safely be entrusted with the remedying of defects which no human foresight could well anticipate.

As for the essential differences between the new system and those already at work, it may be said, briefly, that these are such as the conditions of the country make needful, and are also such as the engineer can regard with satisfaction as being consonant with true mechanical principles. English people can, of course, become habituated to anything. They grumble greatly at the unpleasant, but if the matter concerns John Bull's pocket the grumble subsides gradually into an indifferent mutter. There is no doubt that numberless span wires across our streets and a double row of poles along each of them would be freely endured if it can be proved satisfactorily that electric traction, when thus carried on, is far more efficient and economical than the methods previously employed; but when success in the last-named direction is just as readily achieved by doing away with all necessity for cross-wires and a double set of poles, it would seem no more than fair to claim for the system the prominence that it deserves.

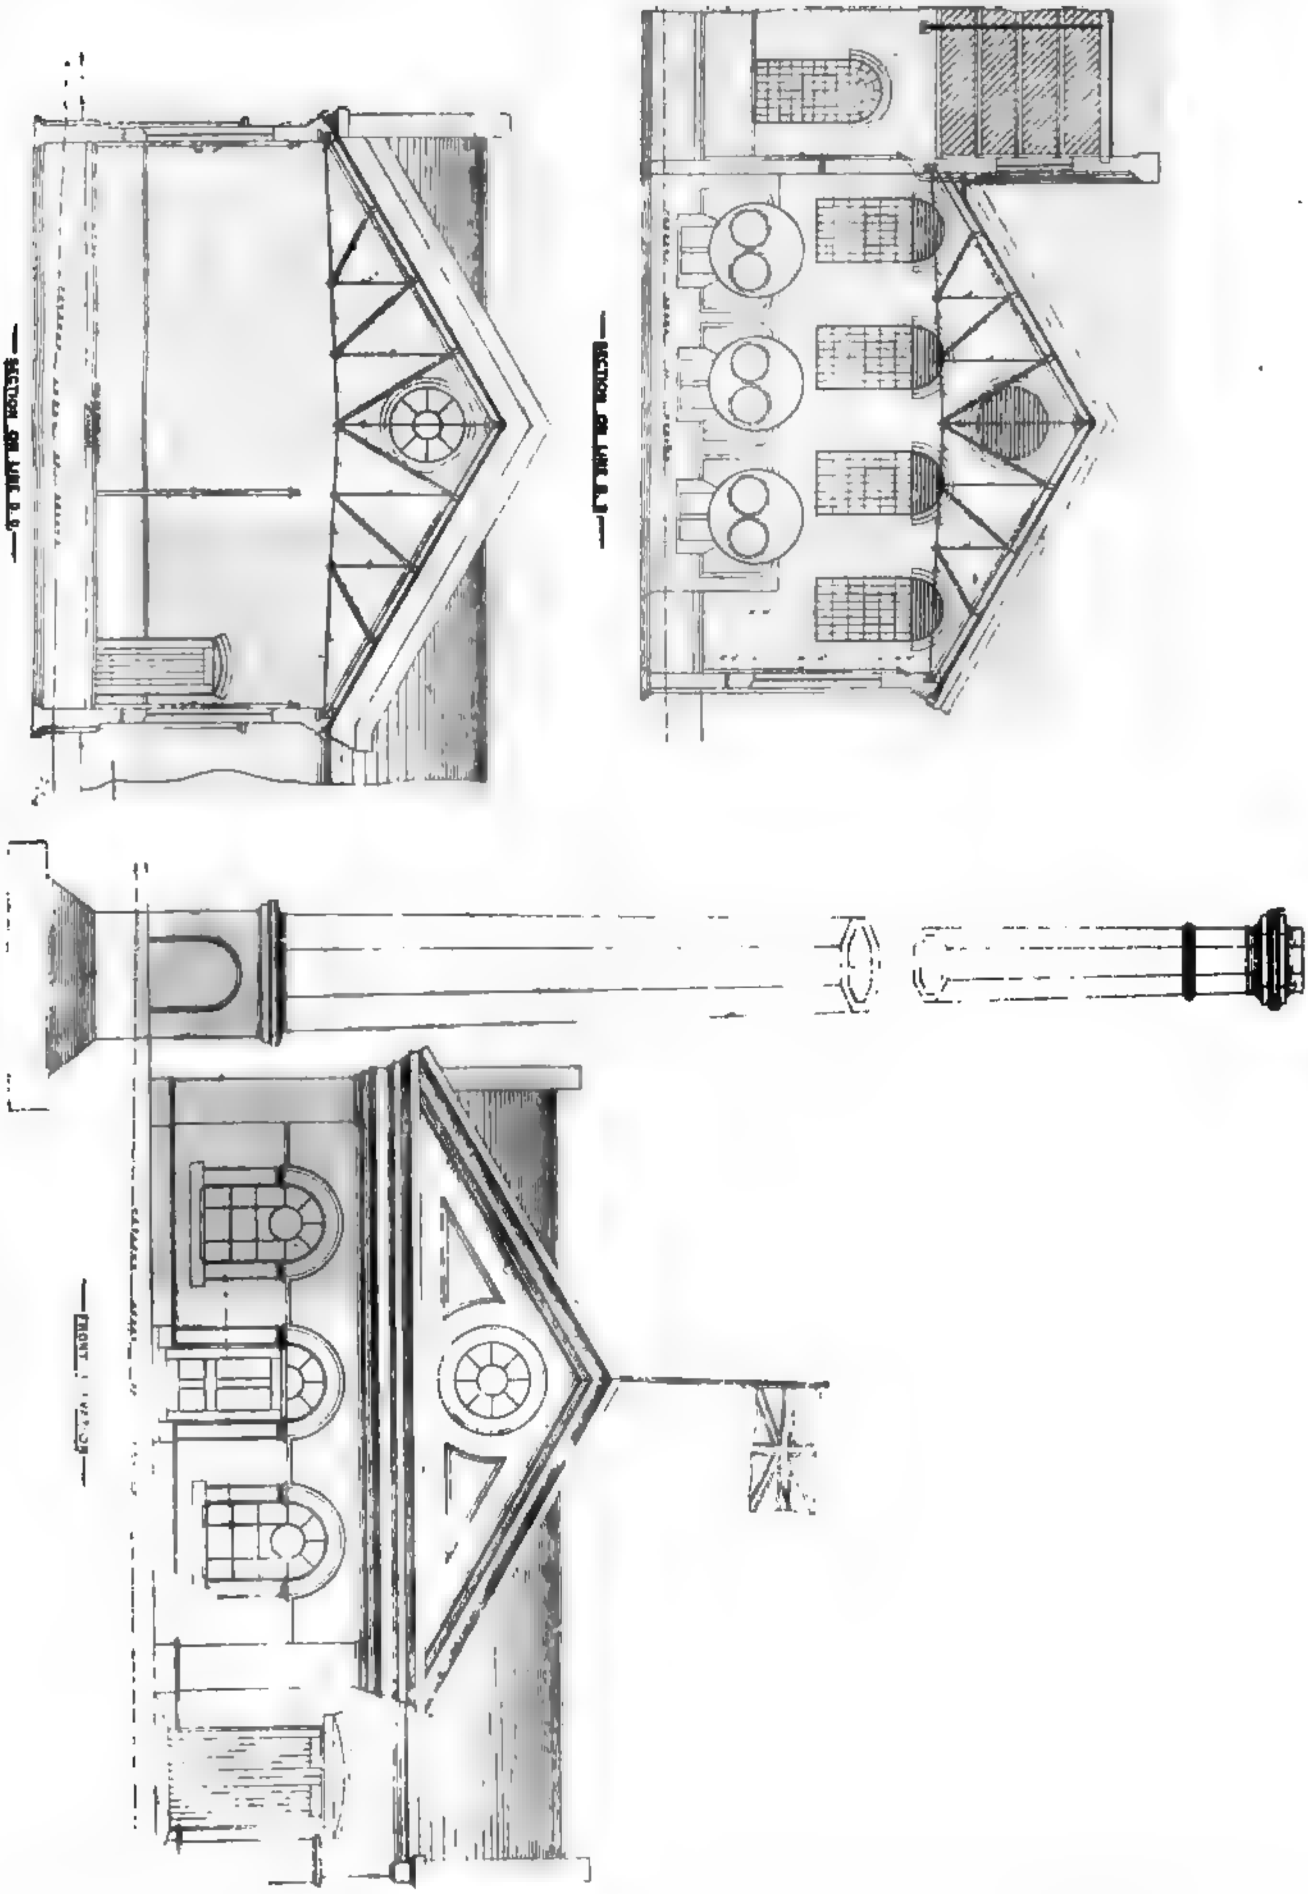
With these introductory remarks, the course is somewhat cleared for a detailed account of the system and appliances now in use on the South Staffordshire line.

View of Generating Station, with Car on Line.

Since electrical energy is the agent employed for operating the line, any description of its leading features might perhaps, to follow out or trace the current of electricity from its origin or introduction to its complete utilisation; and by following this plan it will be more easy to give the essential details in their most suitable order and place.

The electric generating station, from which the overhead conductor system is supplied with electrical energy for operating the car motors in the usual way by travelling connections, is situated at James Bridge, almost in the centre of the district covered by the lines worked electrically. Its position is shown very clearly upon the map which was published in last week's issue. The building itself is of a plain unpretentious nature, with the appearance of having been designed for practical use rather than ornament. It has, however, a frontage to the high road with some claim to architectural embellishments of a simple kind. The chief consideration throughout, however, has been to give plenty of room, light, and air, with lofty roofs and ample window space on all sides. Brick is used throughout for the walls, with stone dressings for the windows and front of the building—a heavy stone cornice giving the latter rather an ecclesiastical appearance that is only destroyed by the high chimney stack.

Alongside the depôt it is proposed to build a new arm from the canal, which runs at the rear of the plot of actually existing, but it is too far off—as may be seen from the plan—to prove of material service, and an early



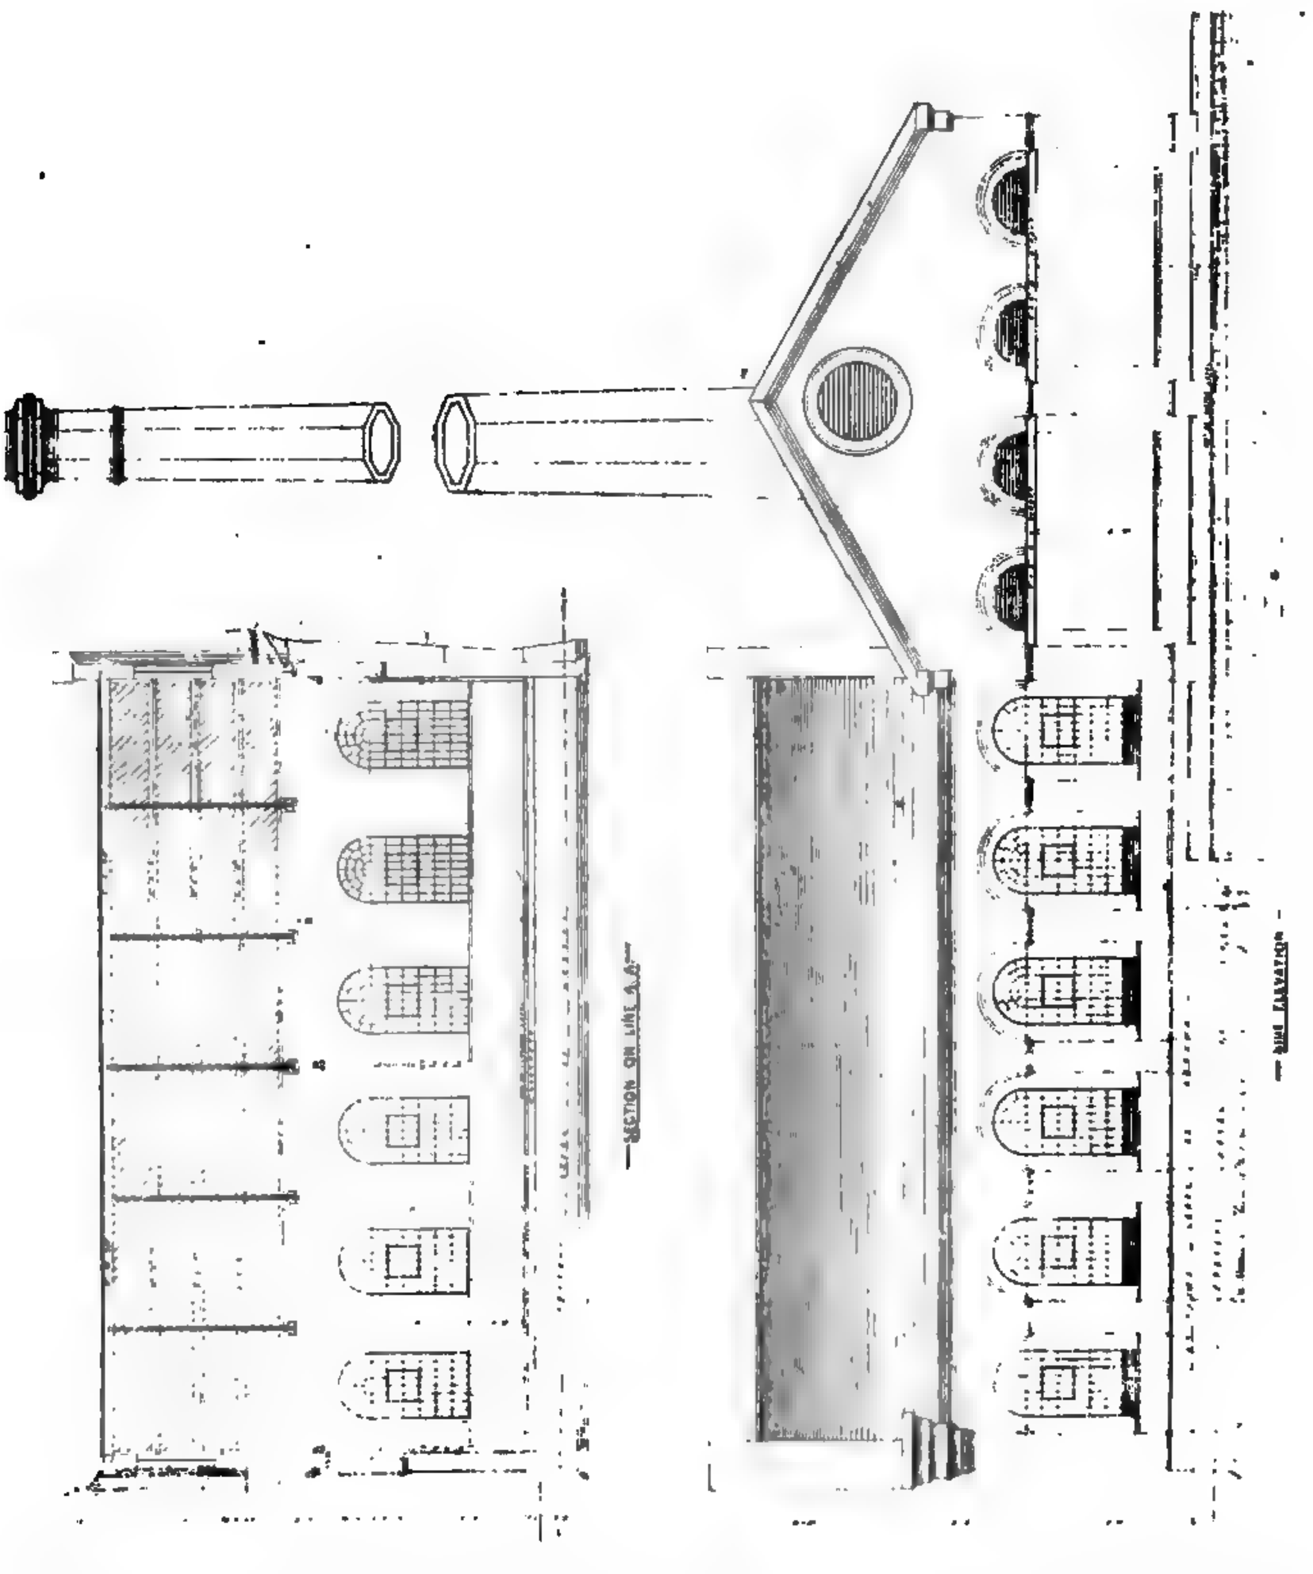
Full and Sectional Elevations of Depot or Generating Station Buildings, showing Boiler House and Engine and Dynamo Room.

land occupied. By this means coal will be taken direct from the barge into the fuel store, thus saving the expense of cartage. There is at present an arm of the canal task, when the line is in working order, will be to complete the new arm. The chimney stack is a substantial erection, but is only noteworthy on account of the climbing

irons built into the brickwork on the inside, so that repairs or alterations may at any future time be carried out with a minimum of trouble and danger.

There comes next to be considered the generating plant contained in the depôt or central station. Three large Lancashire boilers are at present erected for the purpose of raising steam to actuate the engines and, through them, the dynamo generators. Each measures 20ft. in length and 7ft. in diameter, so that they may be regarded as equal to a steam-generating capacity of, say, 200 h.p. each. They are made of steel, with all necessary fittings and appliances, and coming from the works of Messrs. J. Musgrave and Sons, Limited, of Bolton, may be regarded as good examples of Lancashire boilers, having no specially novel features, but representing a type of serviceable and economical steam generators for a purpose where rapid steaming is not so essential as a large steam capacity in case of sudden calls upon the generating station for increase of power along the line.

The three engines to which these boilers supply steam are made by the same firm—Musgrave—and are of the coupled compound horizontal type, with surface condensers. The cylinders measure in diameter 10½in. and 20in. respectively, the stroke in both cases being the same—30in. The valves are of the well-known Corliss type, fitted to both cylinders. The steam pressure employed is 120lb. per square inch. A flywheel, 10ft. in diameter, is fixed to each main engine-shaft, running at 100 revolutions per minute; this, of course, gives a little over 3,000ft. per minute as the velocity of the flywheel rim, and of the ropes which are used to drive the dynamo generators. Each flywheel is grooved for seven ropes, of 1½in. diameter, after the



Elevations of Depot and Generating Station Buildings.

fashion that has been found so successful in many of the large electric supply stations now at work in the Metropolis and elsewhere.

A full supply of water is ensured by the erection of a large tank—shown in the drawings of the depôt published on another page—and in order to secure its good quality for boiler and condenser purposes this reservoir is kept supplied from the South Staffordshire Water Works Company's mains.

Instead of the large sums that have been paid by the tramway company for coke, and other fuel of a more or less smokeless nature, to burn, without creating a nuisance, in the furnaces of the steam tramway locomotives hitherto employed, it is to be hoped that a very great saving will be effected in fuel alone by the adoption of electric energy as the operating agent, since the stationary boilers can be kept satisfactorily at work with fuel costing a good deal less than the 20s. to 22s. per ton hitherto paid for coke of a specially smokeless nature.

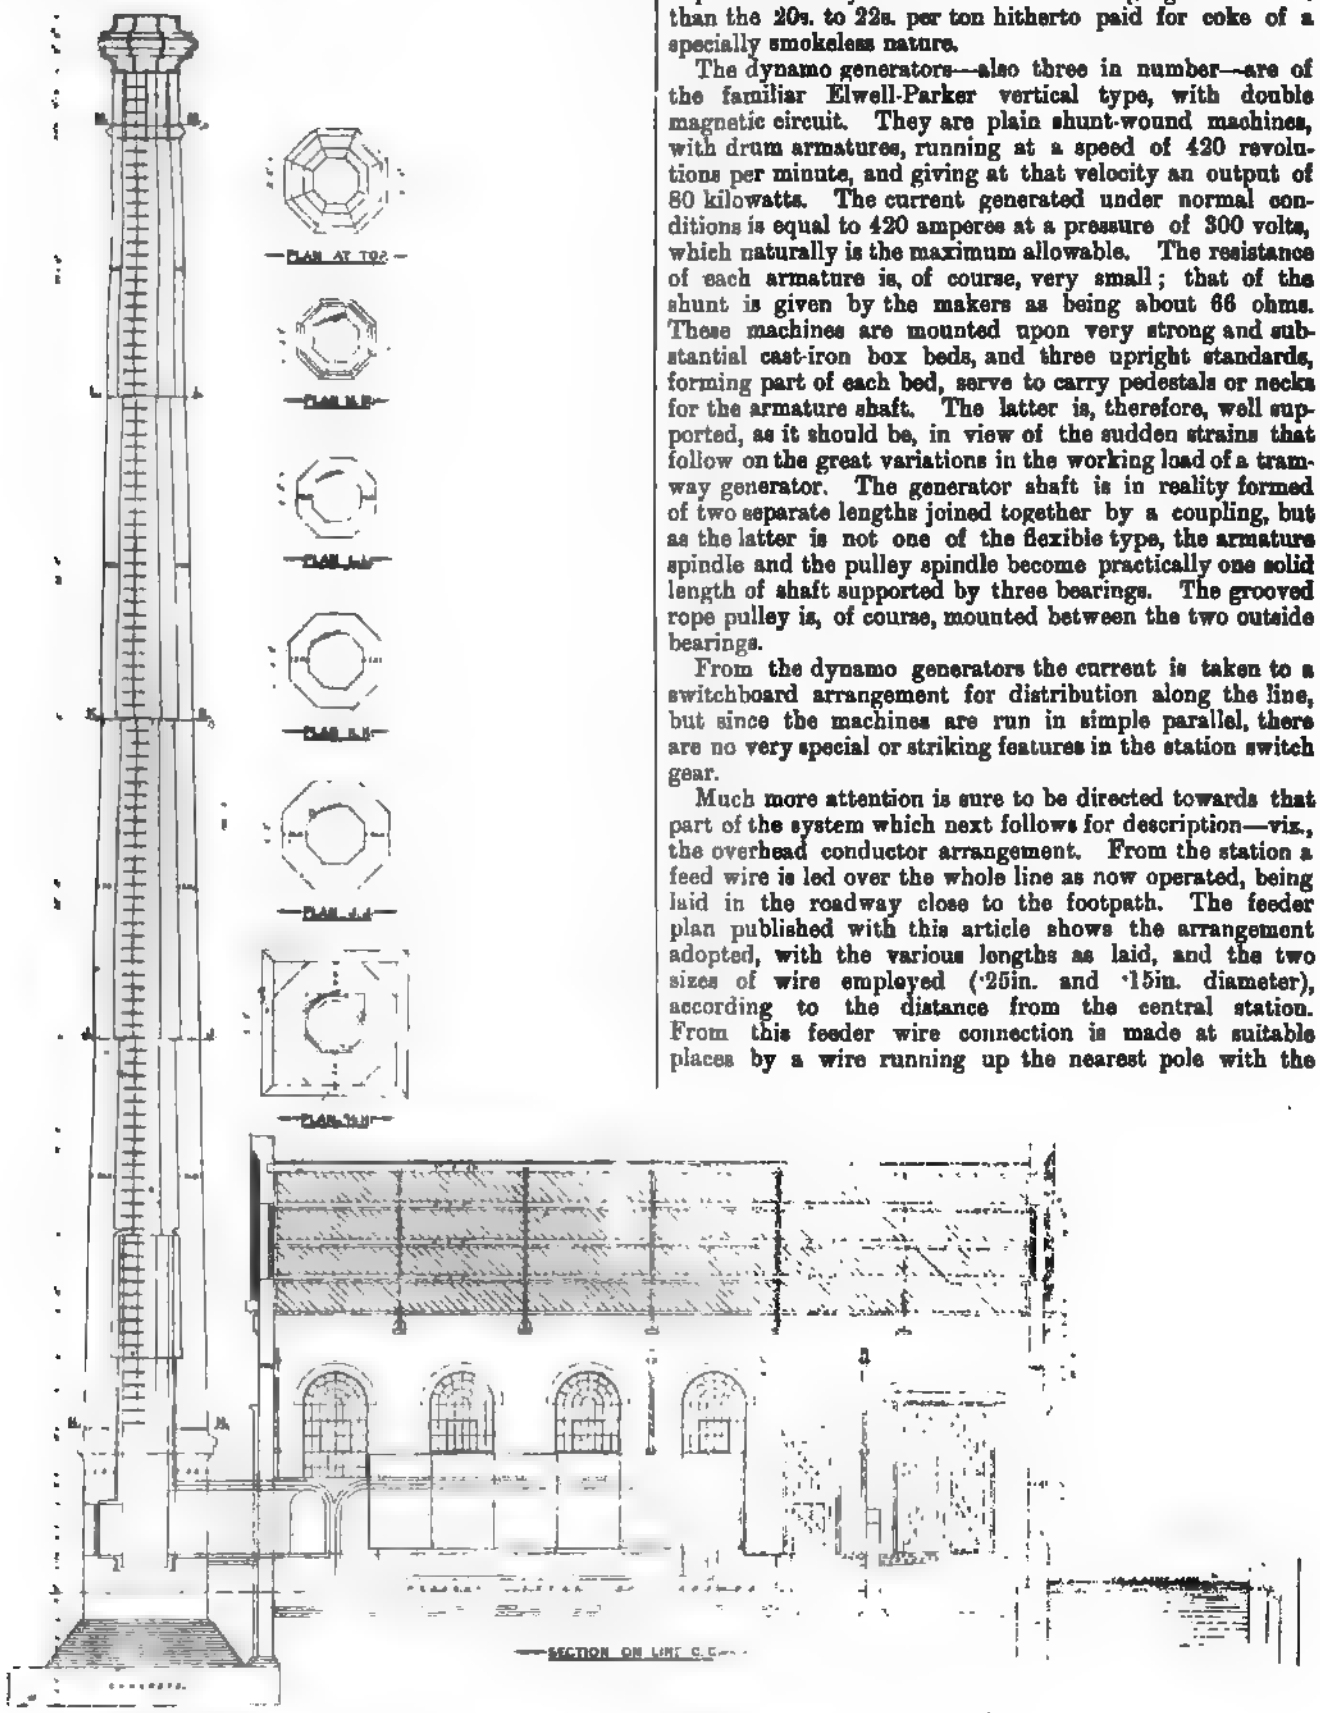
The dynamo generators—also three in number—are of the familiar Elwell-Parker vertical type, with double magnetic circuit. They are plain shunt-wound machines, with drum armatures, running at a speed of 420 revolutions per minute, and giving at that velocity an output of 80 kilowatts. The current generated under normal conditions is equal to 420 amperes at a pressure of 300 volts, which naturally is the maximum allowable. The resistance of each armature is, of course, very small; that of the shunt is given by the makers as being about 66 ohms. These machines are mounted upon very strong and substantial cast-iron box beds, and three upright standards, forming part of each bed, serve to carry pedestals or necks for the armature shaft. The latter is, therefore, well supported, as it should be, in view of the sudden strains that follow on the great variations in the working load of a tramway generator. The generator shaft is in reality formed of two separate lengths joined together by a coupling, but as the latter is not one of the flexible type, the armature spindle and the pulley spindle become practically one solid length of shaft supported by three bearings. The grooved rope pulley is, of course, mounted between the two outside bearings.

From the dynamo generators the current is taken to a switchboard arrangement for distribution along the line, but since the machines are run in simple parallel, there are no very special or striking features in the station switch gear.

Much more attention is sure to be directed towards that part of the system which next follows for description—viz., the overhead conductor arrangement. From the station a feed wire is led over the whole line as now operated, being laid in the roadway close to the footpath. The feeder plan published with this article shows the arrangement adopted, with the various lengths as laid, and the two sizes of wire employed (·25in. and ·15in. diameter), according to the distance from the central station. From this feeder wire connection is made at suitable places by a wire running up the nearest pole with the trolley wire, that hangs from an insulator of ordinary swivelled form at the end of the bracket on the pole.

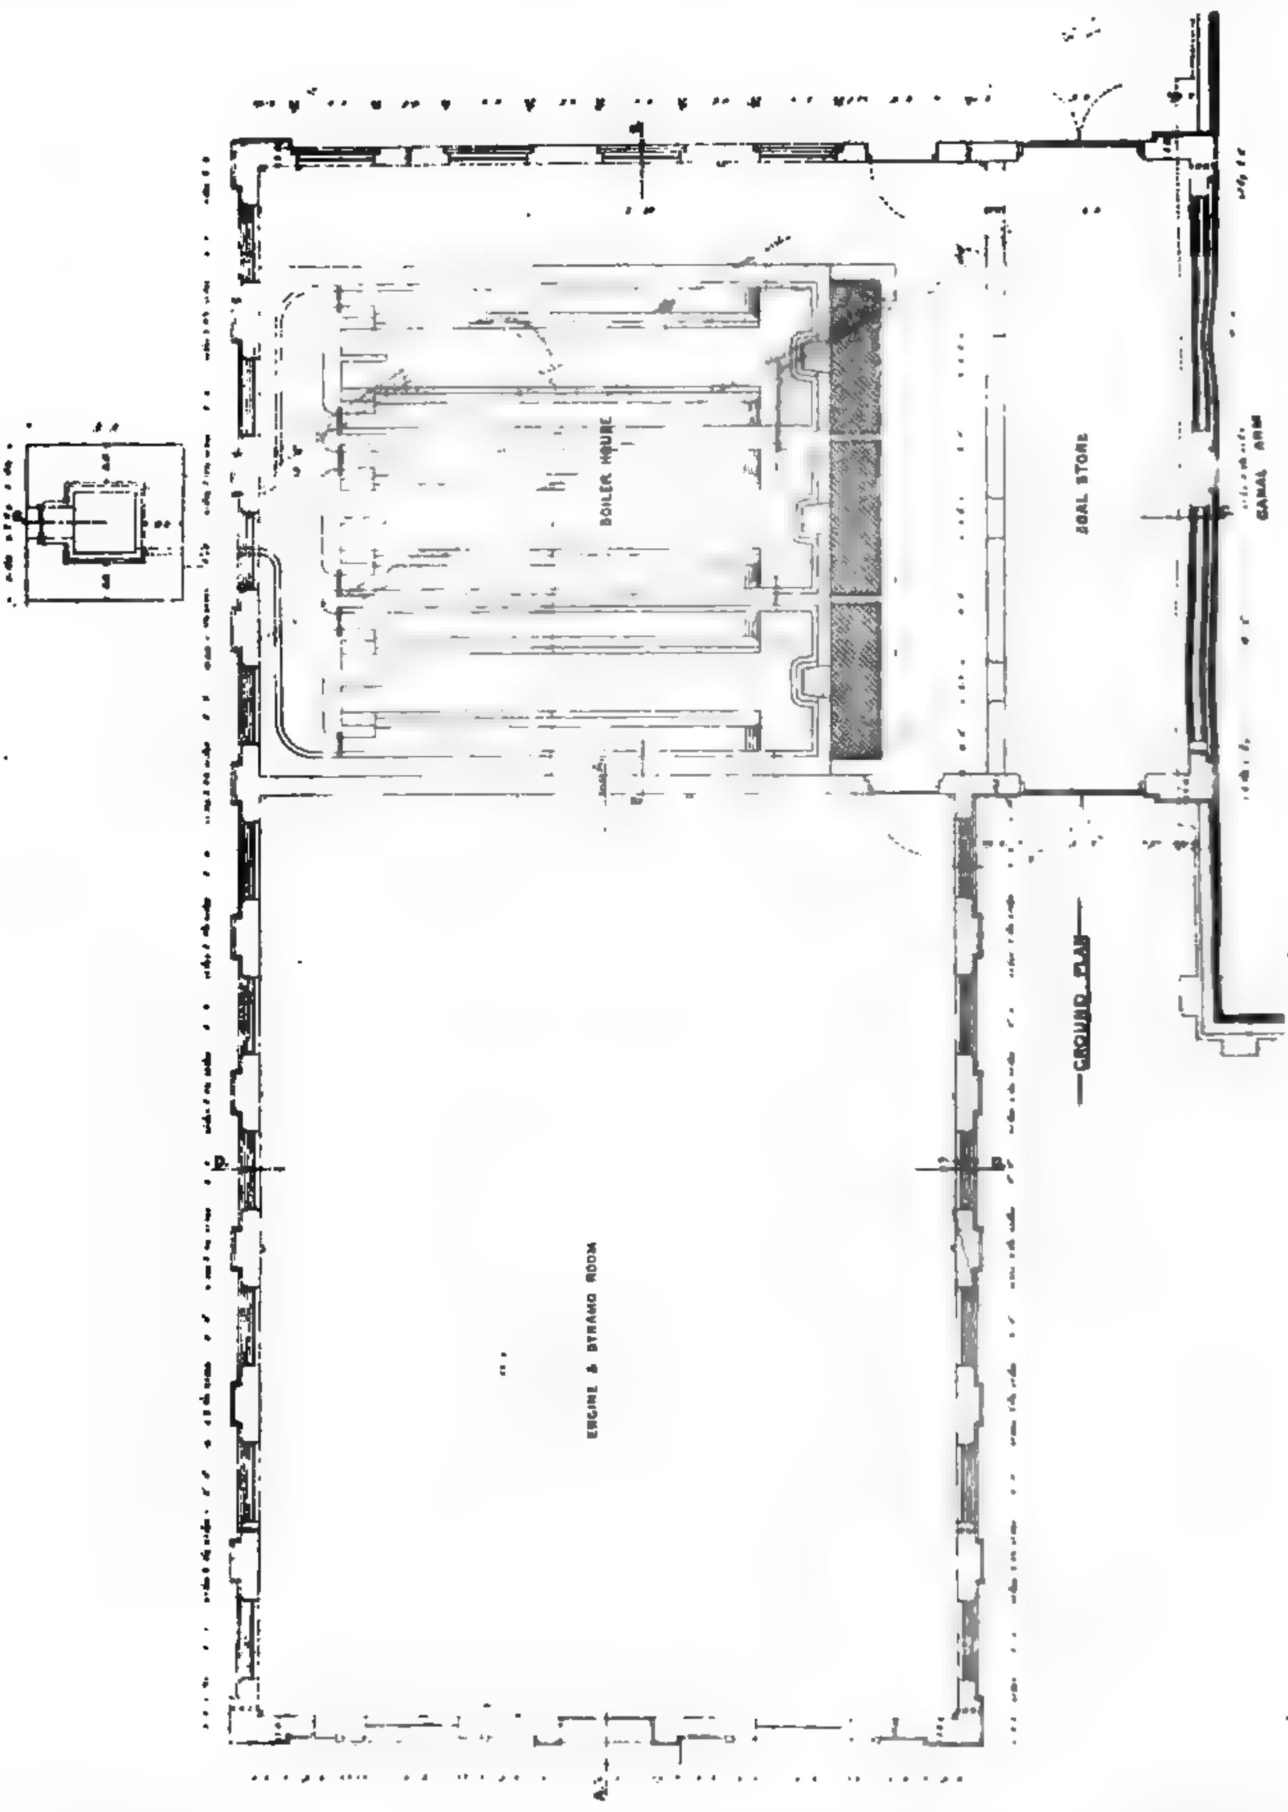
The poles erected along one side only of the road for the purpose of carrying the trolley wire are of neat but plain form.

In detail, however, they present many noteworthy



Sectional Elevation of Boiler House and Chimney Stack, with Sectional Plans of the latter

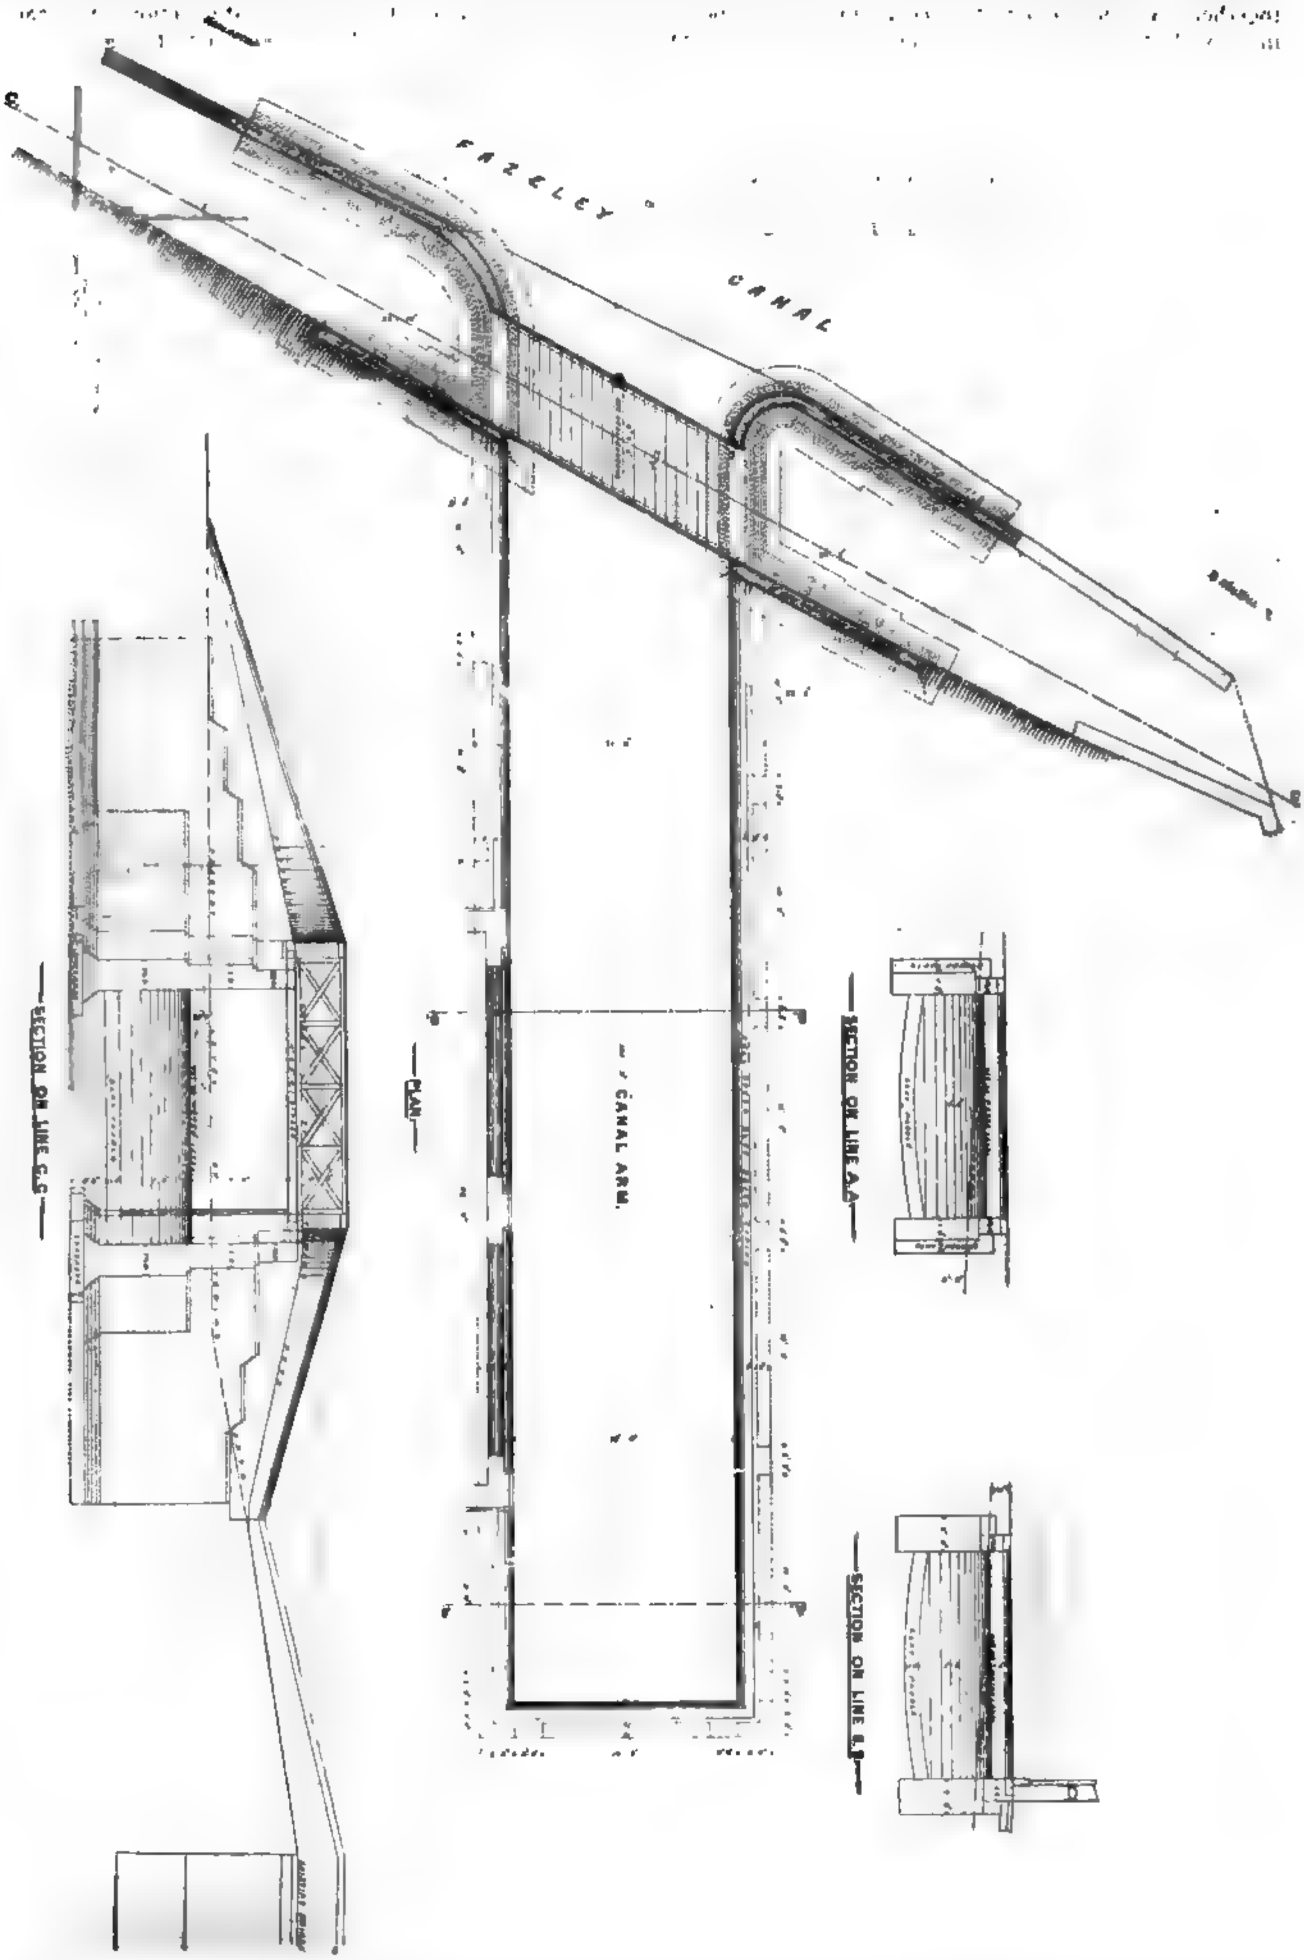
features, and a full description of these poles—their component parts and the manner in which they are put together—will not be out of place at this point, especially in view of the extent to which public opinion must in a



General Plan of Depot or Generating Station Buildings.

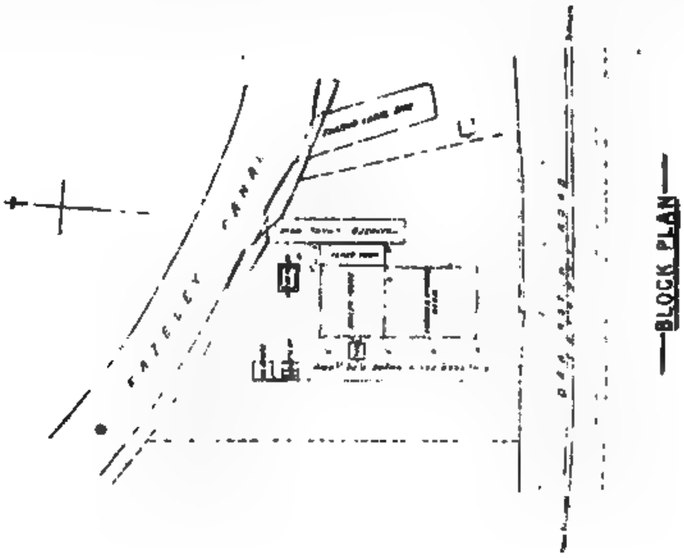
natter of this kind be given free scope for expression as to ;eneral effect. The sizes of poles adopted at present are hree in number—viz., those with bases 6in., 7in., and 2in. diameter respectively. Of the largest type only a · required, these being necessary at points where the strains upon the overhead system are at their maximum—as, for instance, at junctions and terminal points. Else where, and along the intermediate sections, the smalle sizes are employed. All the poles are of mild-steel tube the 12in. having ½in. thickness of metal, whilst the smaller ones are found to possess sufficient strength for their work with a thickness of ¼in. The poles now erected are the outcome of considerable experimenting on the part of the contractors and Messrs. James Russell and Sons, Wednesbury

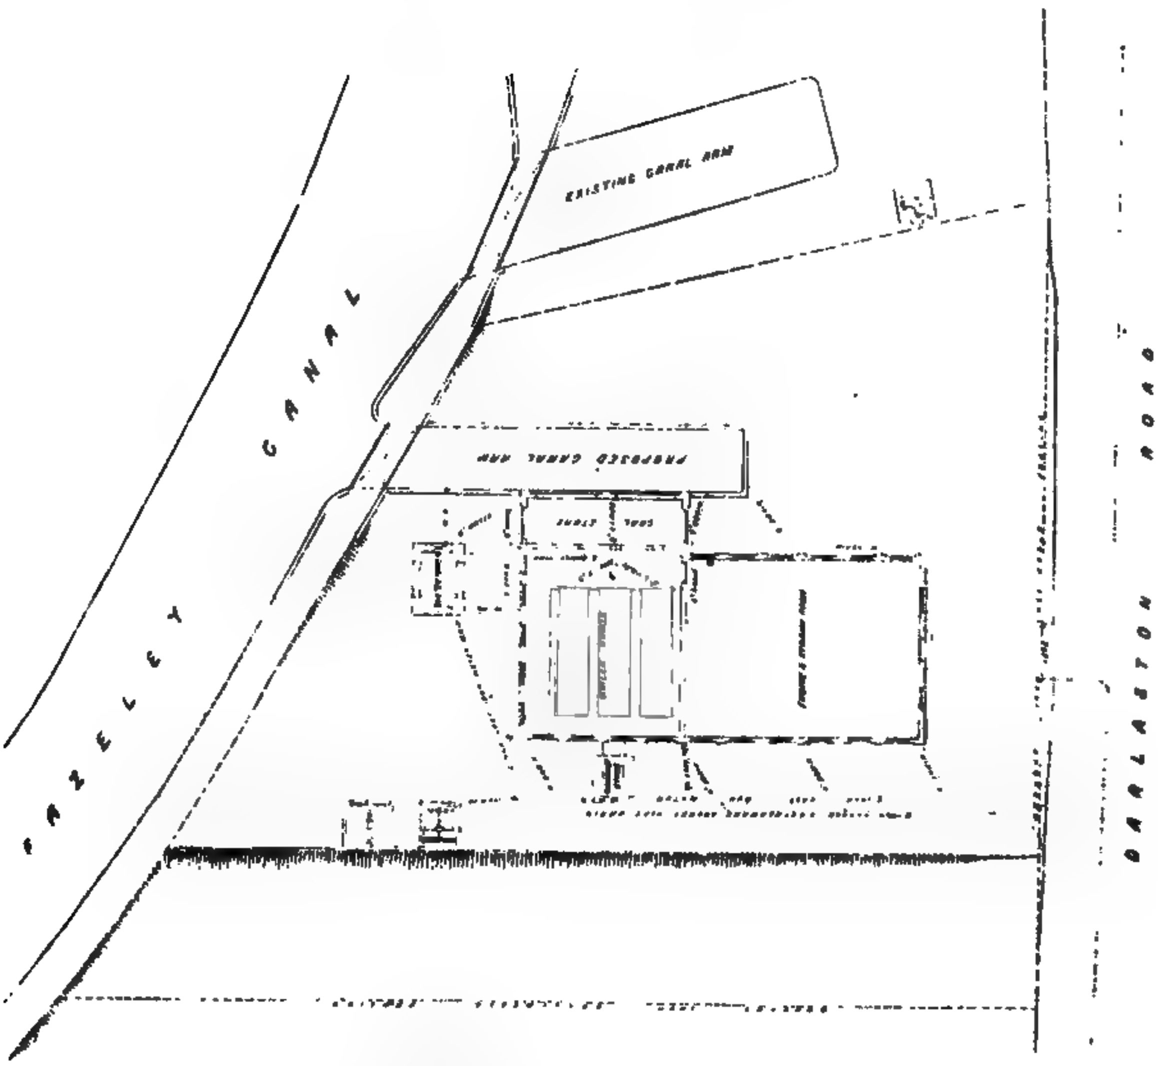
the firm which has made the greater part of the poles. Those first erected for trial were too heavy, and therefore expensive, whilst at the same time of cumbersome appearance. These faults, however, can hardly be alleged now against the poles finally chosen; their appearance is neat, while it is found in practice that they possess an ample reserve of strength to withstand any ordinary strain. It is doubtful even whether the force of a collision with



Plan and Sections of New Canal Arm alongside Coal Store.

runaway vehicles (the only serious possibility) would have any more effect upon the smallest-sized pole than the attack of Stephenson's hypothetical cow upon his locomotive. The 12in. poles measure over all a length of about 32ft.; of this amount a distance of 6ft. 4in. represents the part sunk into the ground below the pathway level. The smaller poles are nearly of the same height, but a less dis-





tance—5ft. 10in.—sunk into the ground suffices in their case, and the trolley wire is thus kept at pretty much the same average height above the roadway. This height may be taken at 21ft.

Each pole is practically composed of two separate parts or tubes. In the case of the 12in. size, the bottom portion *is of the same* diameter throughout—*i.e.*, 11in. internally—and measures in length 10ft. 10½in., of which, as stated, rather more than half is underground.

To anchor the bottom portion firmly to the ground, two heavy cast-iron base-plates are provided, one of which is fixed at the extreme end of the base, and the other about 5ft. higher—*i.e.*, about 16in. below the ground level. These base-plates are made in two halves, to fit round the tube, and are bolted together so as to firmly clamp the latter. In addition to this, they each rest upon a wrought-iron flanged collar, riveted to the tube at the points above named. The intermediate space between the plates—and, indeed, right up to the ground level—is filled in with concrete.

At a distance of 3ft. above the ground level, a wrought

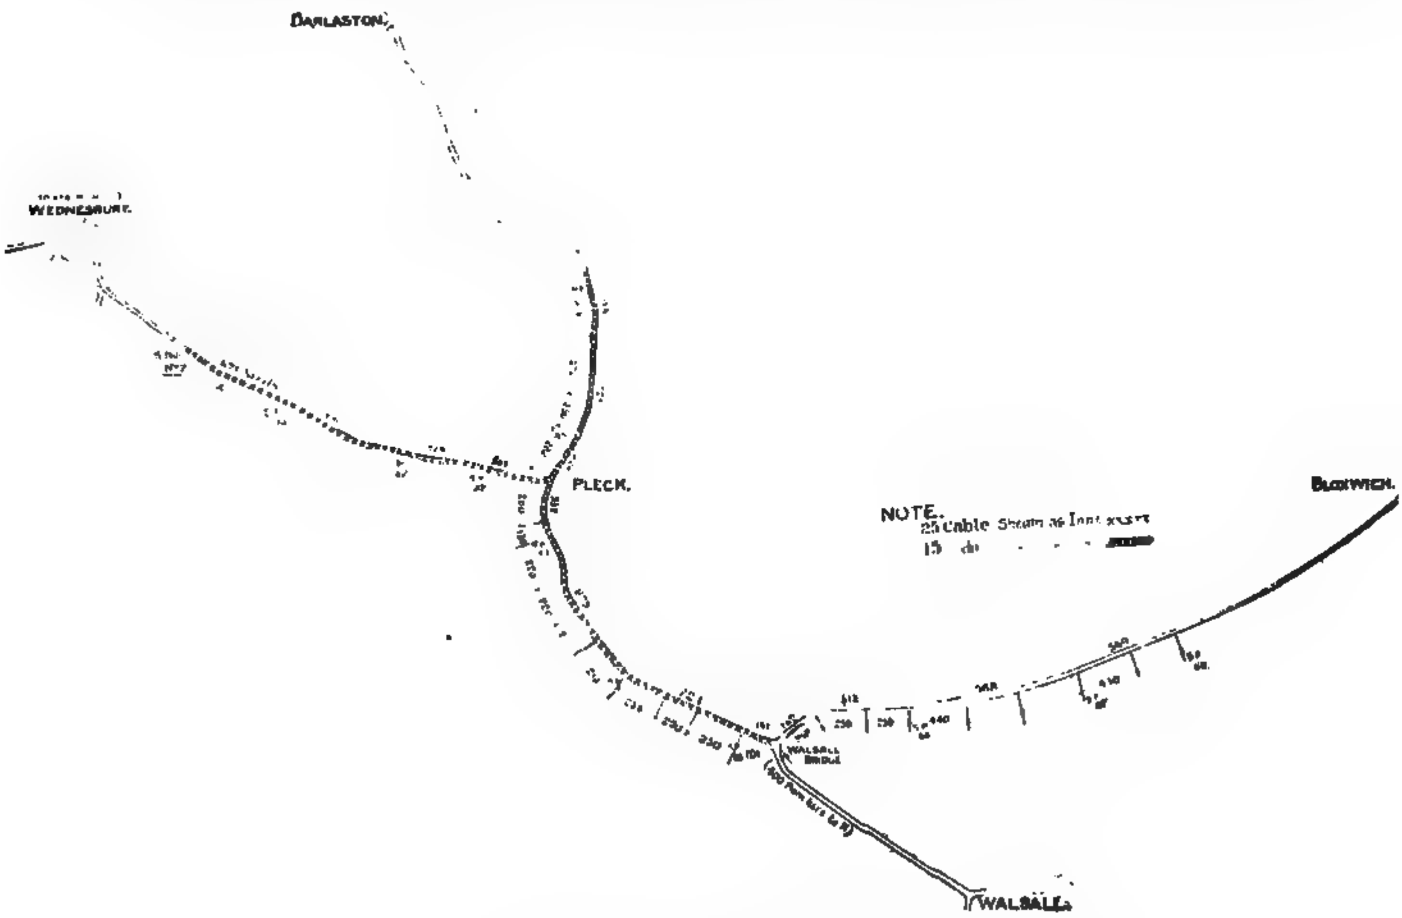
iron collar, measuring 2in. by $\frac{3}{8}$in., is riveted to the inside of the bottom tube in order to serve as a support for the base of the top tube. The latter has a length of 20ft. 5in., a cast-iron finial, measuring 12in. in length, being screwed into the top, which is, of course, plugged for its reception, the plug being welded in. This tube has a considerable taper, being 11in. at the base, whilst at the top it is only $5\frac{1}{4}$in., both dimensions being those of external diameter. Each one is fitted at the makers' works into the bottom tube whilst the latter is hot, so as to obtain a shrinking fit. A length of 15in. is considered sufficient overlap; but as a further means of ensuring a good solid joint a wrought-iron collar, 2in. by 1in., is shrunk on to the top of the bottom tube after the top tube has been fitted in. Above this collar is fixed an ornamental waist moulding by means of screws with countersunk heads.

The smaller types of poles—that is, the 6in. and 7in. sizes—do not require quite such a substantial foundation as the larger ones; and instead of two heavy cast-iron base-plates, a single one is found sufficient. This is made

upon the poles. At the tee end the arm tube measures $2\frac{3}{8}$in. external diameter; this is tapered down to $1\frac{1}{4}$in. at the outer or projecting end, into which, when plugged, a small cast-iron finial is finally screwed.

At the outer end of the arm tube a split tubular clip is fixed by means of a $\frac{1}{2}$in. bolt, passing through lugs or ears; from this clip is hung, below the arm, the insulator and trolley wire clamp, whilst the tightening bolt just referred to serves also to secure one end of a long wrought-iron strap, $\frac{3}{8}$in. by $1\frac{3}{16}$in., that passes to a similar split collar or clip fastened to the top of the pole, and serving as a guy to keep the arm or bracket in proper tension against the weight of itself and the trolley wire, etc. Insulating collars of indiarubber are inserted between each of these clips and the post or arm, as the case may be.

The trolley wire is of solid drawn copper, 312·5 mils in diameter. At the insulators or points of suspension it is firmly gripped by a metal strap bent upwards, and riveted to a double claw, which presses down upon the wire. The latter is therefore firmly held against end motion, and the



Map showing Arrangement of Feeders.

of wrought iron, is 2ft. 3in. square, and no thicker than $\frac{1}{4}$in. The centre part is pressed upwards, or buckled, to a depth of some $2\frac{1}{4}$in. To the bottom of each pole is riveted a wrought-iron collar, $1\frac{3}{8}$in. by $\frac{3}{8}$in., bent out between the rivets, to give four corners, or lugs. Through these are passed $\frac{3}{4}$in. bolts, which also pass through the base-plate, and are secured underneath by nuts. Other details of the foundation work may be gathered from the drawings given herewith.

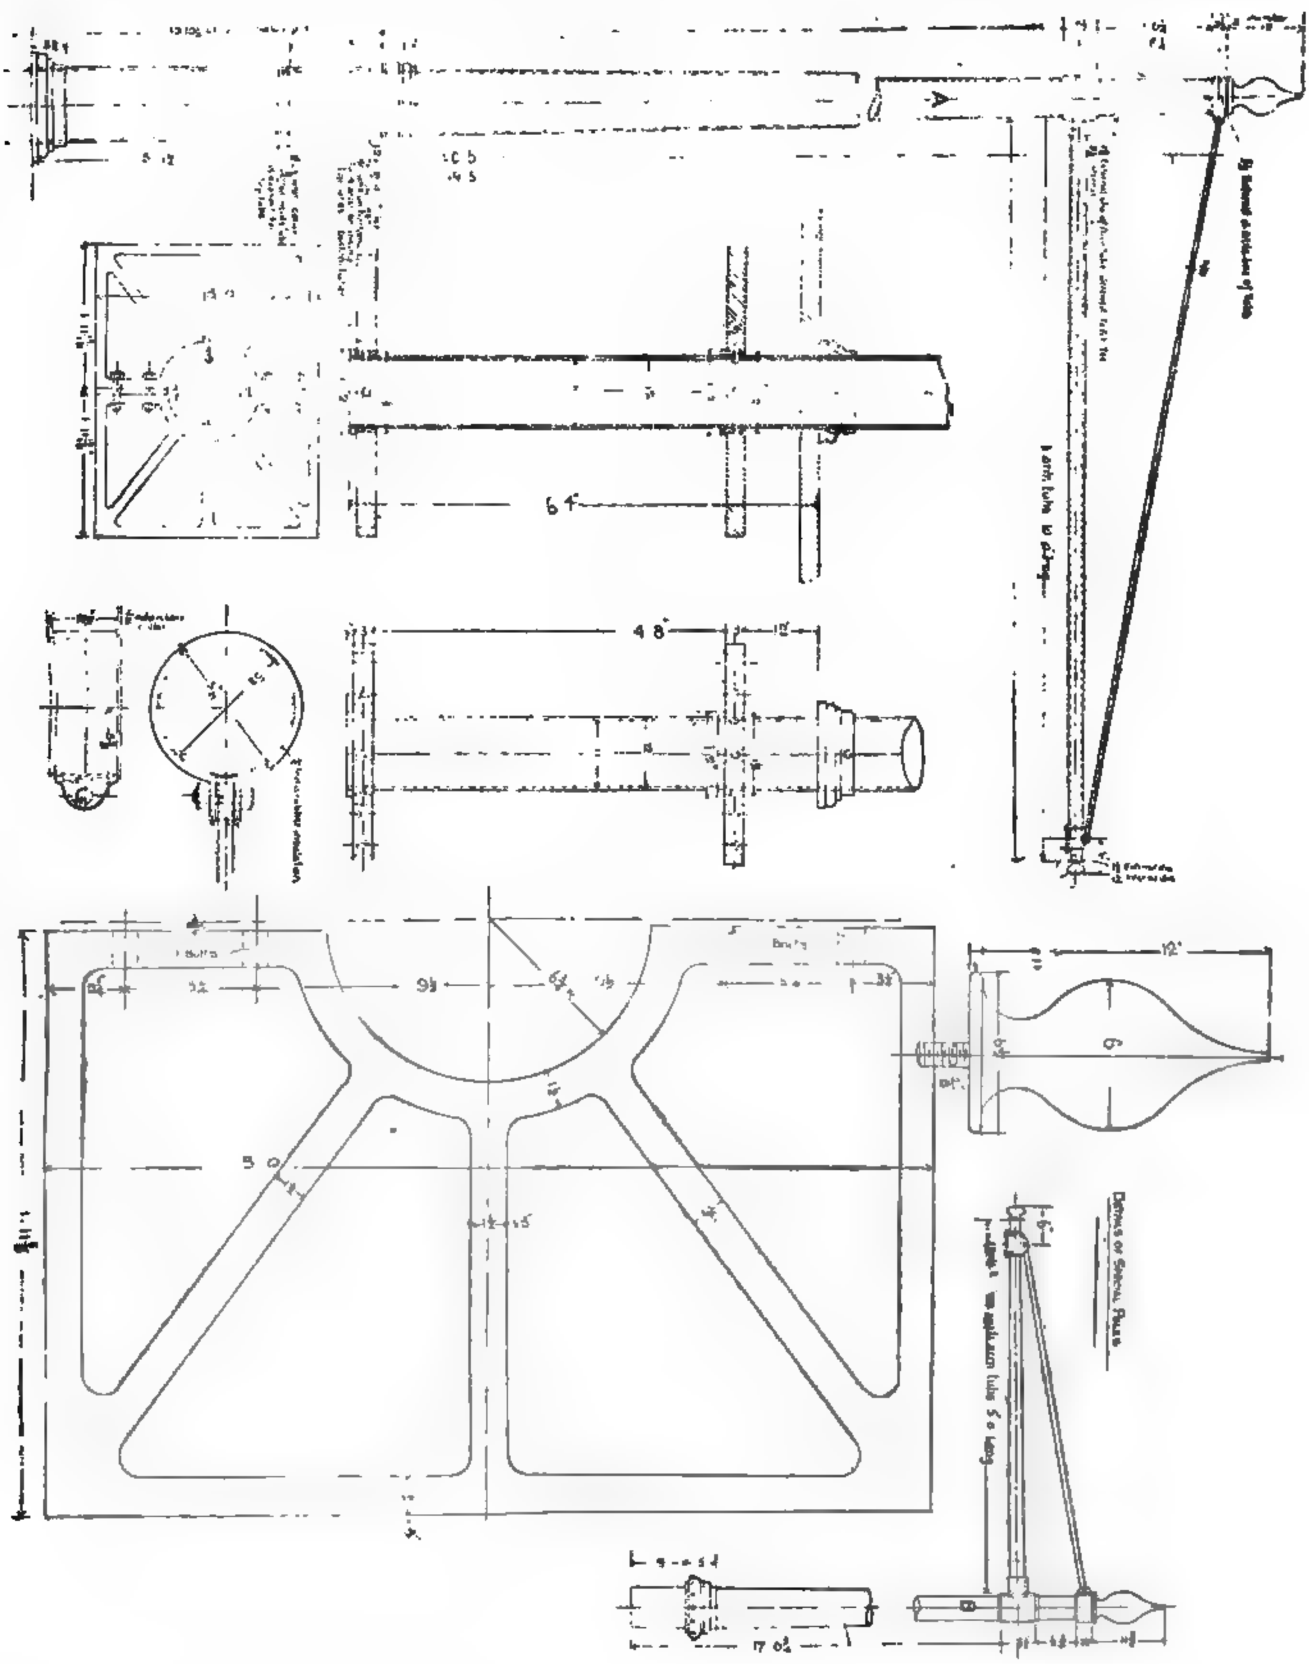
At an average height of some 21ft. above the roadway, as already stated, an arm or bracket extends from each pole over the roadway to support the insulator and trolley wire fastened thereto. The length of this arm varies, of course, with the distance of the rails from the sidewalk; in some cases it is not more than 2ft. 6in. long, in others it is 5ft., 7ft., 8ft., 9ft., and 10ft., the latter, of course, being required where the line is double, so that the trolley wire is branched on two insulators, both fixed, however, to the one arm. Each arm or bracket—all of which are made of steel tubes similarly to the poles—is fastened to the latter by being simply screwed into a tee firmly shrunk

compression of the clamp arrangement serves to give the wire a slight bend upwards, thus not only gripping it more tightly, but presenting a level surface underneath for the trolley wheel to press against, since the thickness of the metal strap fills up the gap otherwise left by bending the wire upwards. The clamp swings on a bolt secured by washer and pin to a metal fork screwed on a stud. The latter again is screwed into a flange-headed socket let into the insulator. The insulators are indeed prepared by the makers with this socket in position, and also with a brass cap on the top, having a turned-in lip round the lower circumference. The insulating material is thus moulded in between the socket for the stud and the brass protecting cap. The latter is cast with a long bearing at the top, through which passes a bolt secured by lock nuts to the fork of the split collar or tubular clamp, already spoken of as being fixed at the end of the pole arm or bracket. Details of this arrangement are given in the drawings now published.

Turning now to the trolley itself, it may be said that although usage allows the expression to be employed, yet the common idea conveyed by the word "trolley," is not

the required purpose of collecting current from the overhead wire. This wheel is grooved V-shaped, but with a circular base to the groove, in order to grip as much of the wire as possible. It is mounted in a fork, whose tops are curved slightly inwards so as nearly to touch the wheel flanges. Light springs are attached to the inside of the fork, pressing against the wheel and keeping it in position. A pin, or light spindle — on which the wheel runs — passes through the fork, being secured at one end by its own countersunk head, and at the other by a split pin. A capacious oil reservoir is very ingeniously placed under the wheel, with a tube and wick, or wiper, leading upwards so as to bear against the shoulder where the wheel hub butts upon the side of the fork, and thus supply plenty of lubricant.

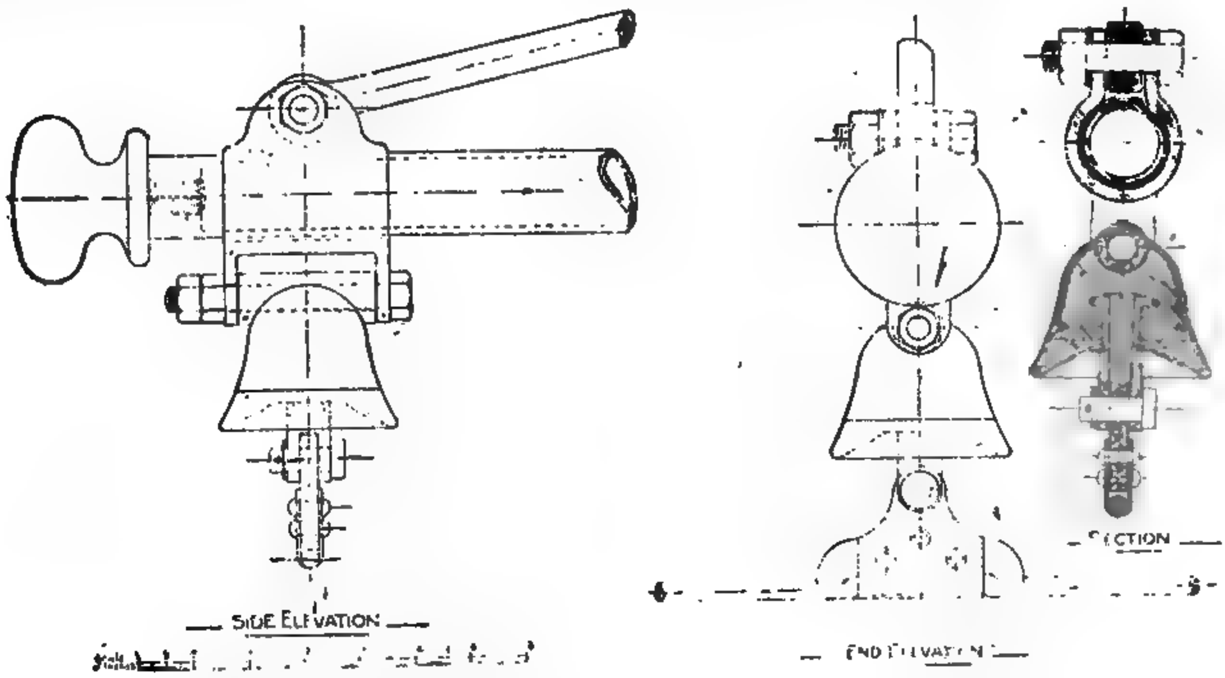
The chief novelty of the whole equipment may be said to lie in this greatly improved type of trolley, and also in the trolley-pole fixture—shortly to be described. All those who are interested in, or who have studied overhead conductor electric traction methods, are painfully aware of two facts that have usually proved obstacles of no little importance to the speedy adoption of this otherwise excel lent system. There are, in the first place, incessant variations in the distance between the rails and the line of posts along the footpath or side of the roadway; and, second, the question of satisfactorily taking the



Details of Street Pole—12in. Diameter at Base.

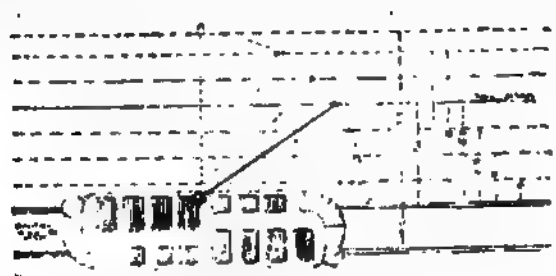
Details of Special Pole.

trolley wire round a curve almost always implies a multitude of guy wires or strainers, which at best only convert the straight wire into a series of chords.

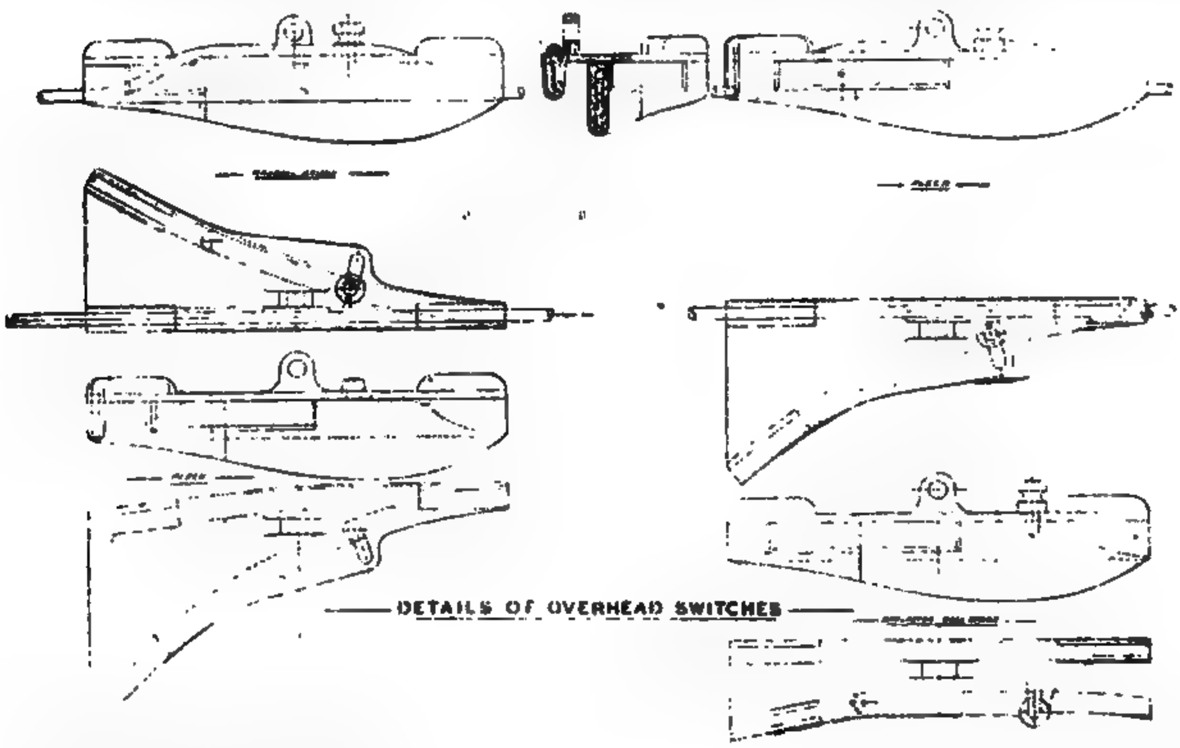


Details of Insulation and Trolley Wire Clamp.

By the arrangement now to be described—chiefly, if not altogether, due to the ingenuity of Mr. A. Dickinson,



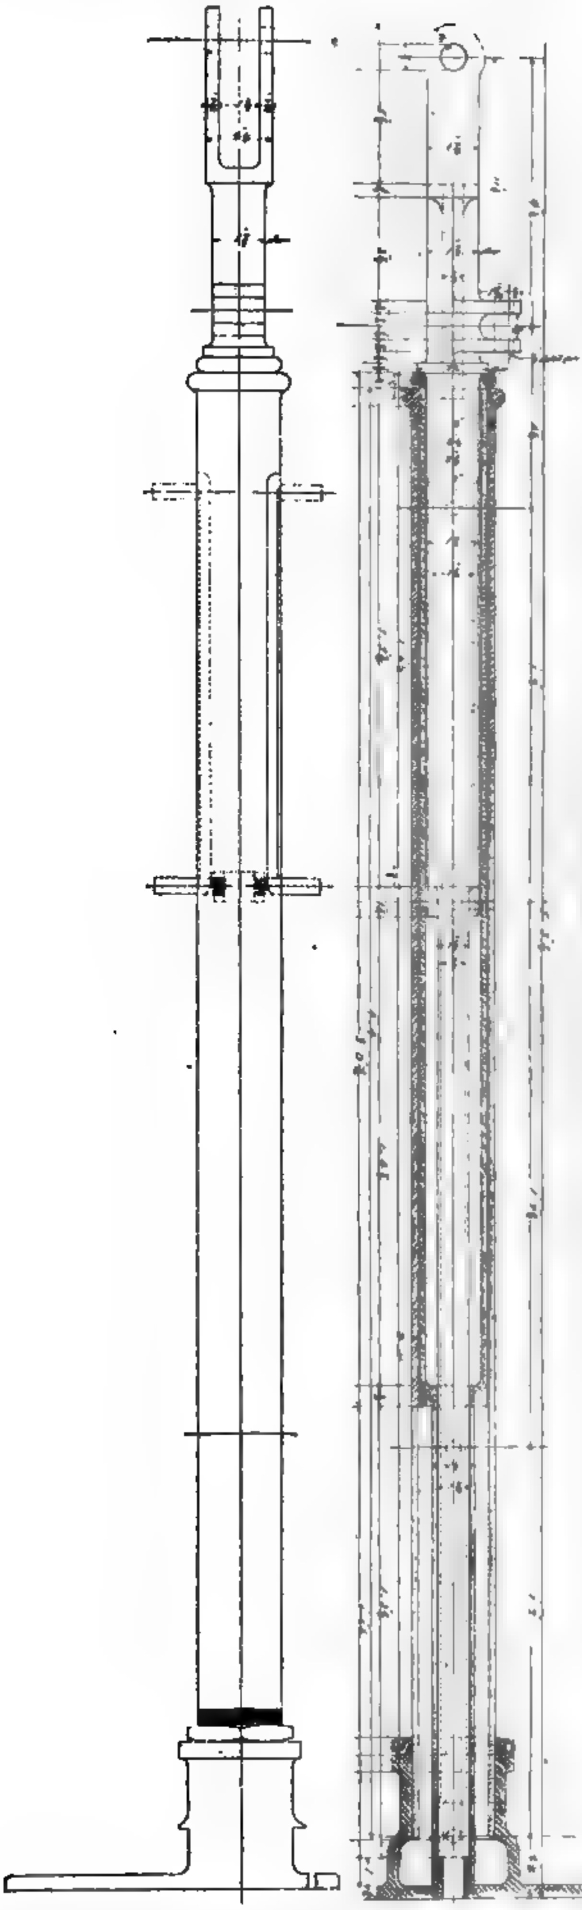
Plan showing Range of Side Movement in Trolley Pole.



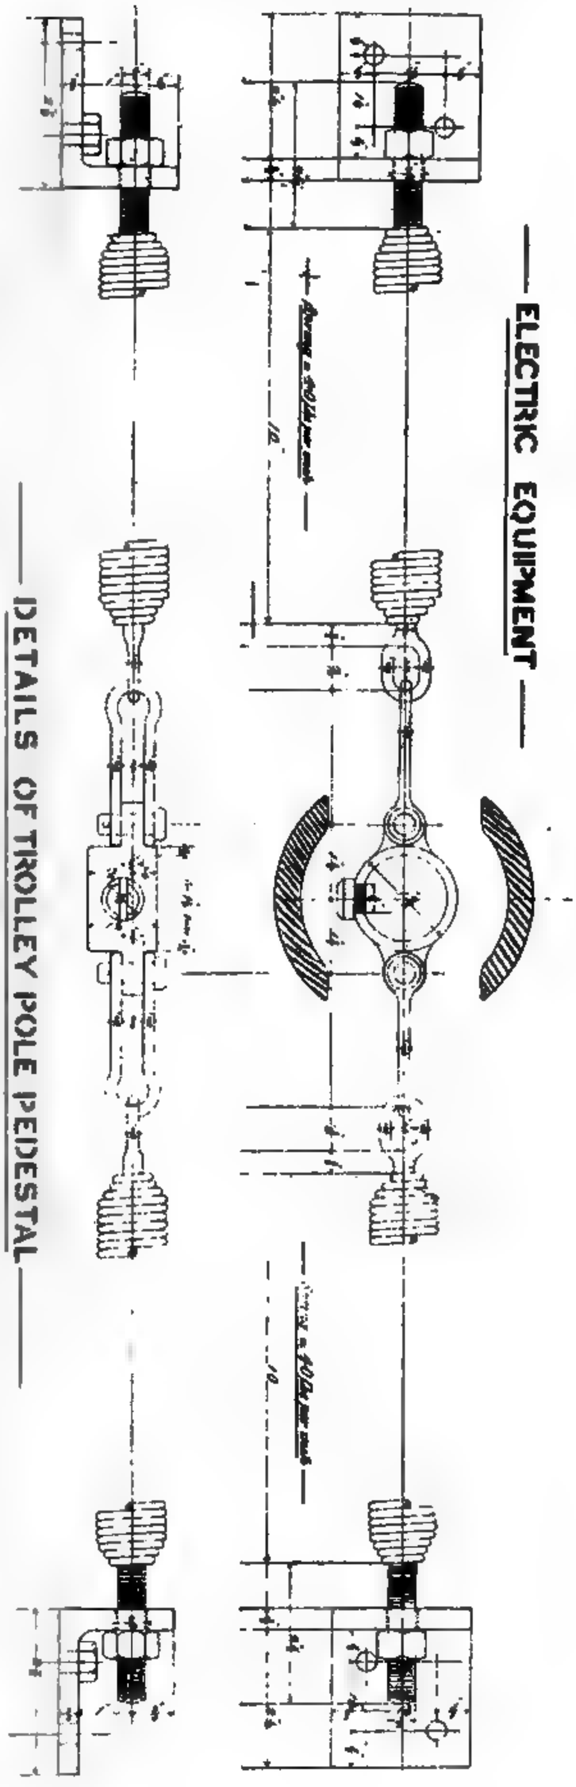
the general manager of this line—no trouble is experienced from either of these sources. The improvement by which the difficulty is overcome simply involves the application of a universal joint. This is done by allowing the trolley pole to swivel in its socket on the top of the car, and the trolley itself also to turn in the socket fixed at the end of the trolley pole and holding the shaft of the fork in which it runs.

When, therefore, the car is 10ft. or 12ft. from the footpath, the trolley pole extends from the side almost at right angles, whilst the trolley itself—keeping always parallel with the wire—is at right angles to the trolley pole. Between this extreme and that in which the trolley pole is parallel with the car—*i.e.*, with an angular motion of 90deg.—there is, of course, ample scope for meeting all conditions of distance from the line of poles, and practically, also, of variation in curvature of the line. The advantages of thus doing away with a large number of guy wires, and also avoiding an excessive length of pole bracket, cannot be too strongly noted; inasmuch as these improvements appear practically to overcome every objection due to prejudice that a British public might bring

ard. The trolley fork is provided with a round shaft, or k, which fits into a socket on the end of the trolley over any desired angle, but prevents it from jumping upwards or being torn out of the socket.



DETAILS OF TROLLEY POLE PEDESTAL

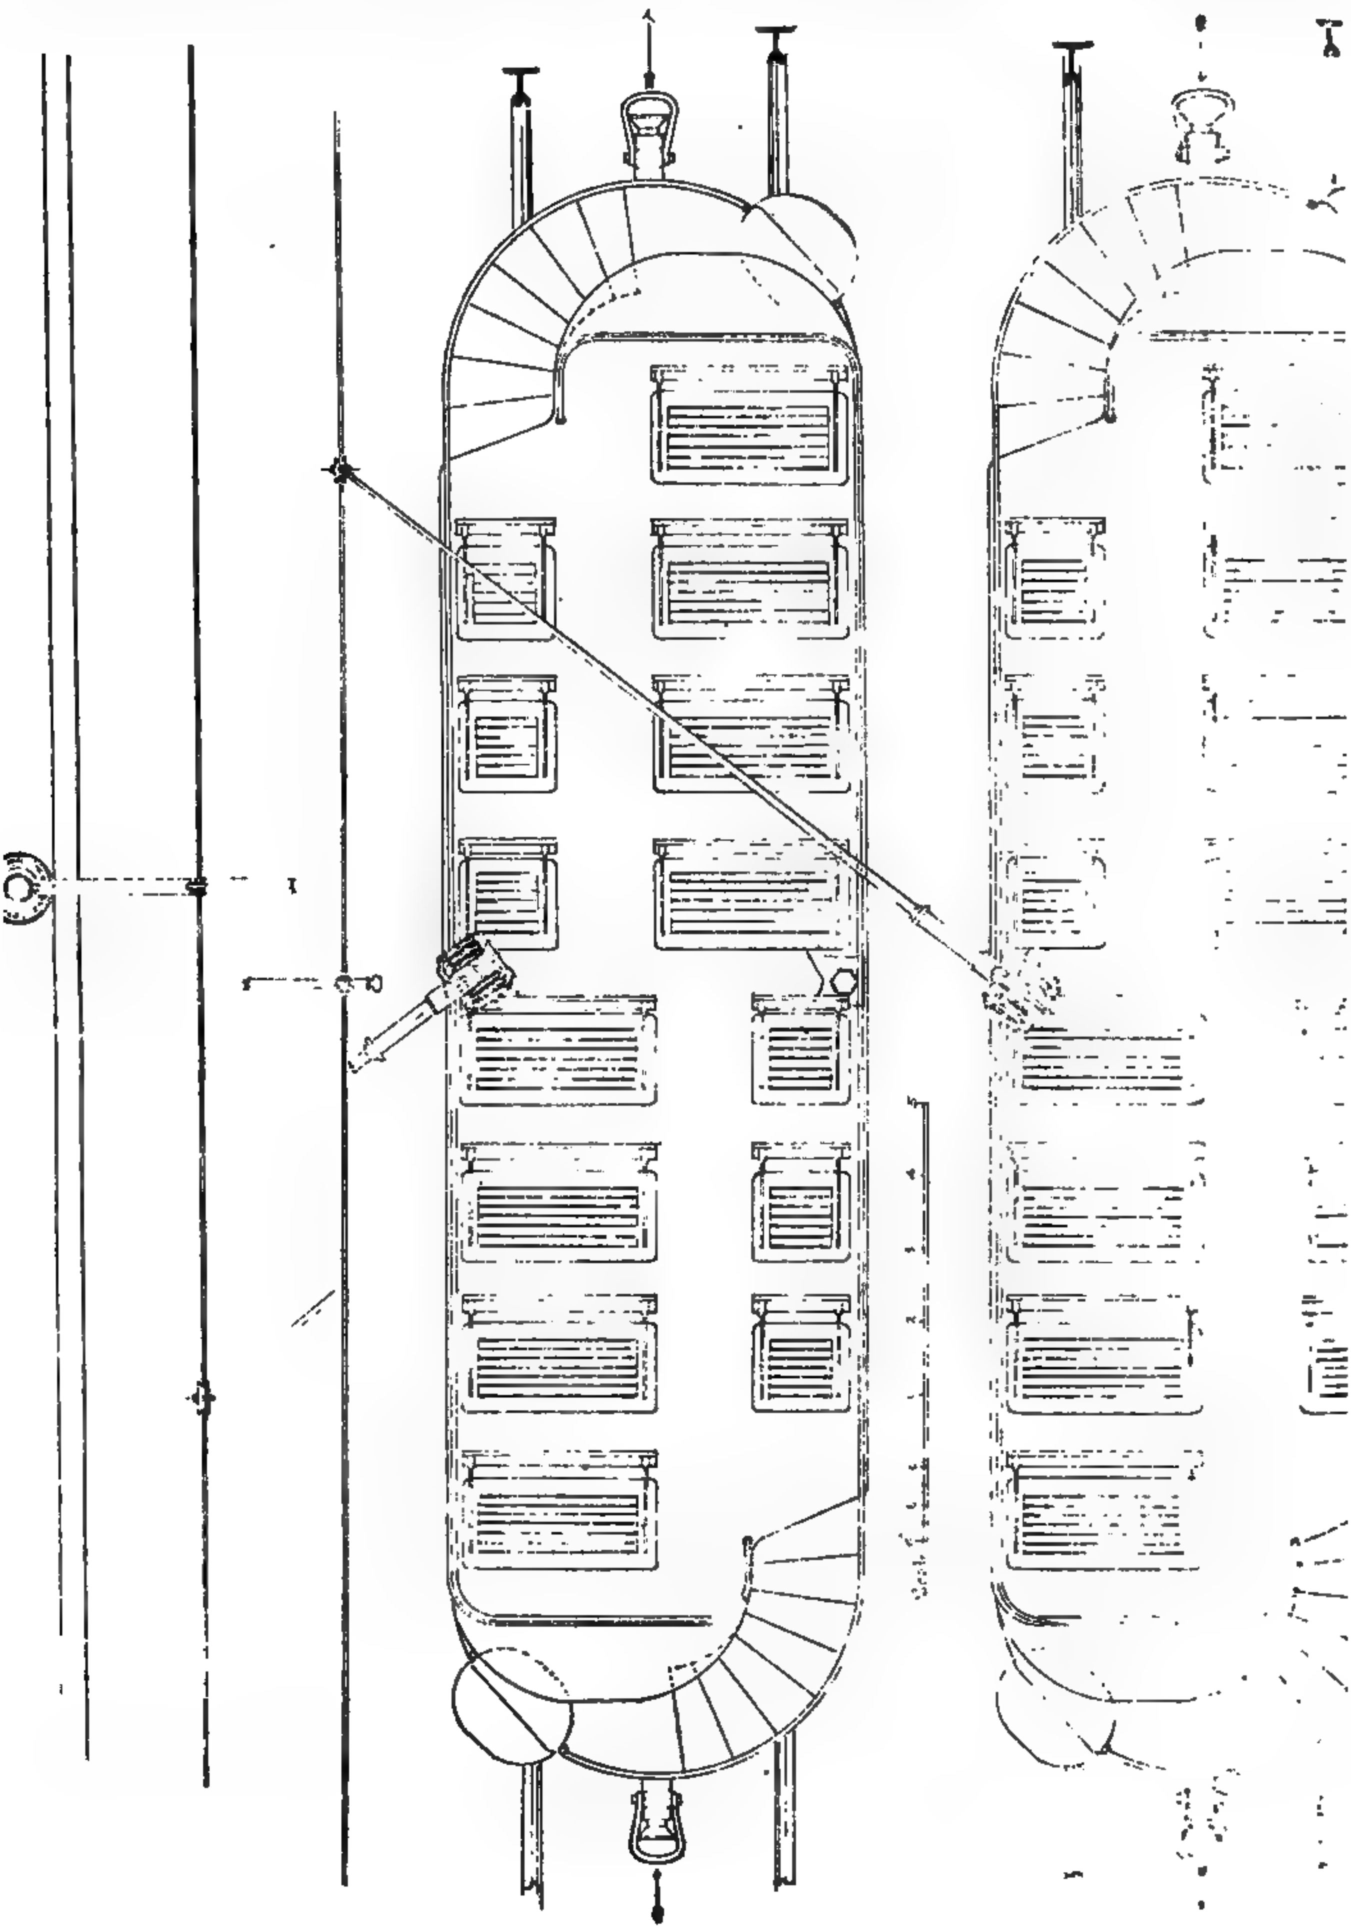


ELECTRIC EQUIPMENT

; a circular grooved keyway is cut round the shaft, a round pin passed through a hole in the socket so as e in the keyway. This allows the shaft to turn freely

The trolley pole is of an extremely simple form. It consists of a stout tube about 3ft. in length, let into and capable of swivelling in a larger tube some 5ft. in height,

mounted upon the top of the car at one side. At the upper end of the shorter tube is pivoted the base of the trolley



pole proper, having an elbow frame joined to it; from the *ter end of the latter strong* spiral springs are secured to the short tube, thus giving the necessary tension upwards the trolley pole and trolley itself against the overhead wir

The greater part of the line is, of course, single. the turn-outs or crossovers, where the line is doubled, tl

street pole brackets are made extra long—up to, say, 10ft. spread—and a double arrangement of insulators provided. The trolley wire junctions themselves are of simple form, and require no comment. The entire question, indeed, of cars passing one another merely implies that the trolley of the car on the near side of the road leaves the main trolley wire for a supplementary one, which is suspended from insulators placed on the bracket arms nearer to the footpath, whilst the other car maintains its trolley upon the main wire. Its trolley pole, however, in order to keep the trolley in position, must cross right over the first car, but the height is amply sufficient to clear everything, and passengers will have no reason to fear that the pole may knock their hats off on a 6ft. clearance above the top of the seats outside.

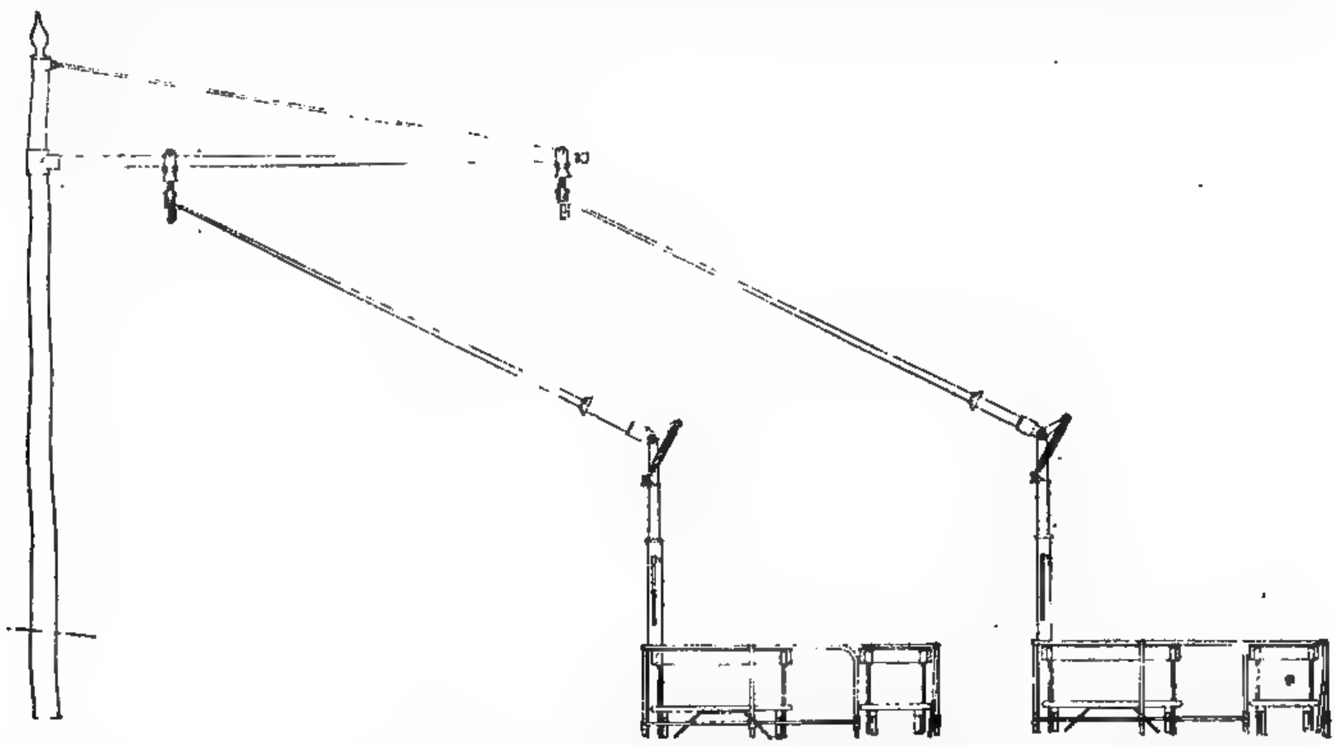
The cars to be employed for this new electric service on the South Staffordshire Company's lines have all been specially built for the purpose by Messrs. Brown, Marshall, and Co., Limited, Saltley, Birmingham, and in this respect the tramway company has doubtless followed a wise course by employing absolutely new rolling-stock rather than take the questionable course of adapting that already in use. It is seldom that satisfaction follows the putting, metaphorically speaking, of new wine into old bottles; although in the case of electric traction it is a comparatively easy and economical matter to convert horse or steam cars into rolling-stock to be driven by electric motors—whether on the accumulator or the conductor system. Anyway, it shows commendable enterprise and a high degree of confidence in the success of the scheme that the tramway company should have equipped the line to be electrically operated with entirely new cars upon which may be fitted more conveniently the latest and best appliances.

If the endeavour had been made to adapt or alter the cars previously used for steam traction on this line, the result would probably have proved unsatisfactory and expensive, owing to consequent modifications in the design throughout. Much heavier motors would have been necessary, the overhead construction of greater capacity, the central station and generating plant of larger output—all this apart from alterations to the cars themselves—although probably the receipts would be little, if any, more. This point is emphasised because in many cases it is pointed out that great economy in capital expenditure should result from simply altering the ordinary cars when electric traction is adopted for any line. This economy is not always existent, though in many cases it may be found: more often it is balanced, and even outweighed, by increased working expenses.

The new cars, which are of one type and design, are double-decked, like those previously used on this line with steam locomotives, but the awning is conspicuous by its absence. Probably no one will miss it; little or no satisfactory protection from the weather is obtained in this way, whilst the extra weight and possibly increased windage must tell against its use. Seating accommodation is provided for 40 passengers—18 inside and 22 on the top. The outside seats are of the "common or garden" form, with reversible backs, and the usual staircase is provided at each end. The length of each car over all measures 22ft., whilst the clear height, apart from the trolley-pole standard, is 12ft. from rail level to top of handrail. A single truck is used underneath the car frame, with 6ft. wheel centres, the amount of overhang at each end being also about the same length (6ft.). The wheels are of cast steel, with mild-steel axles and rolled-steel tires shrunk on; in diameter they measure 2ft. 9in.

Ordinary and emergency hand brakes are provided. These act upon all the wheels, and may be applied from either end of the car by a hand-wheel.

The weight of each car, empty, is stated to be less than $4\frac{1}{2}$ tons without the motors, or, say, six tons including the two motors. Fully loaded with passengers, etc., the total weight may be taken at $8\frac{1}{4}$ tons inclusive. The car interiors are, of course, lighted by electricity, though special arrangements, as on the City and South London line, will doubtless have to be made for this purpose, owing to fluctuations of pressure in the main circuit.



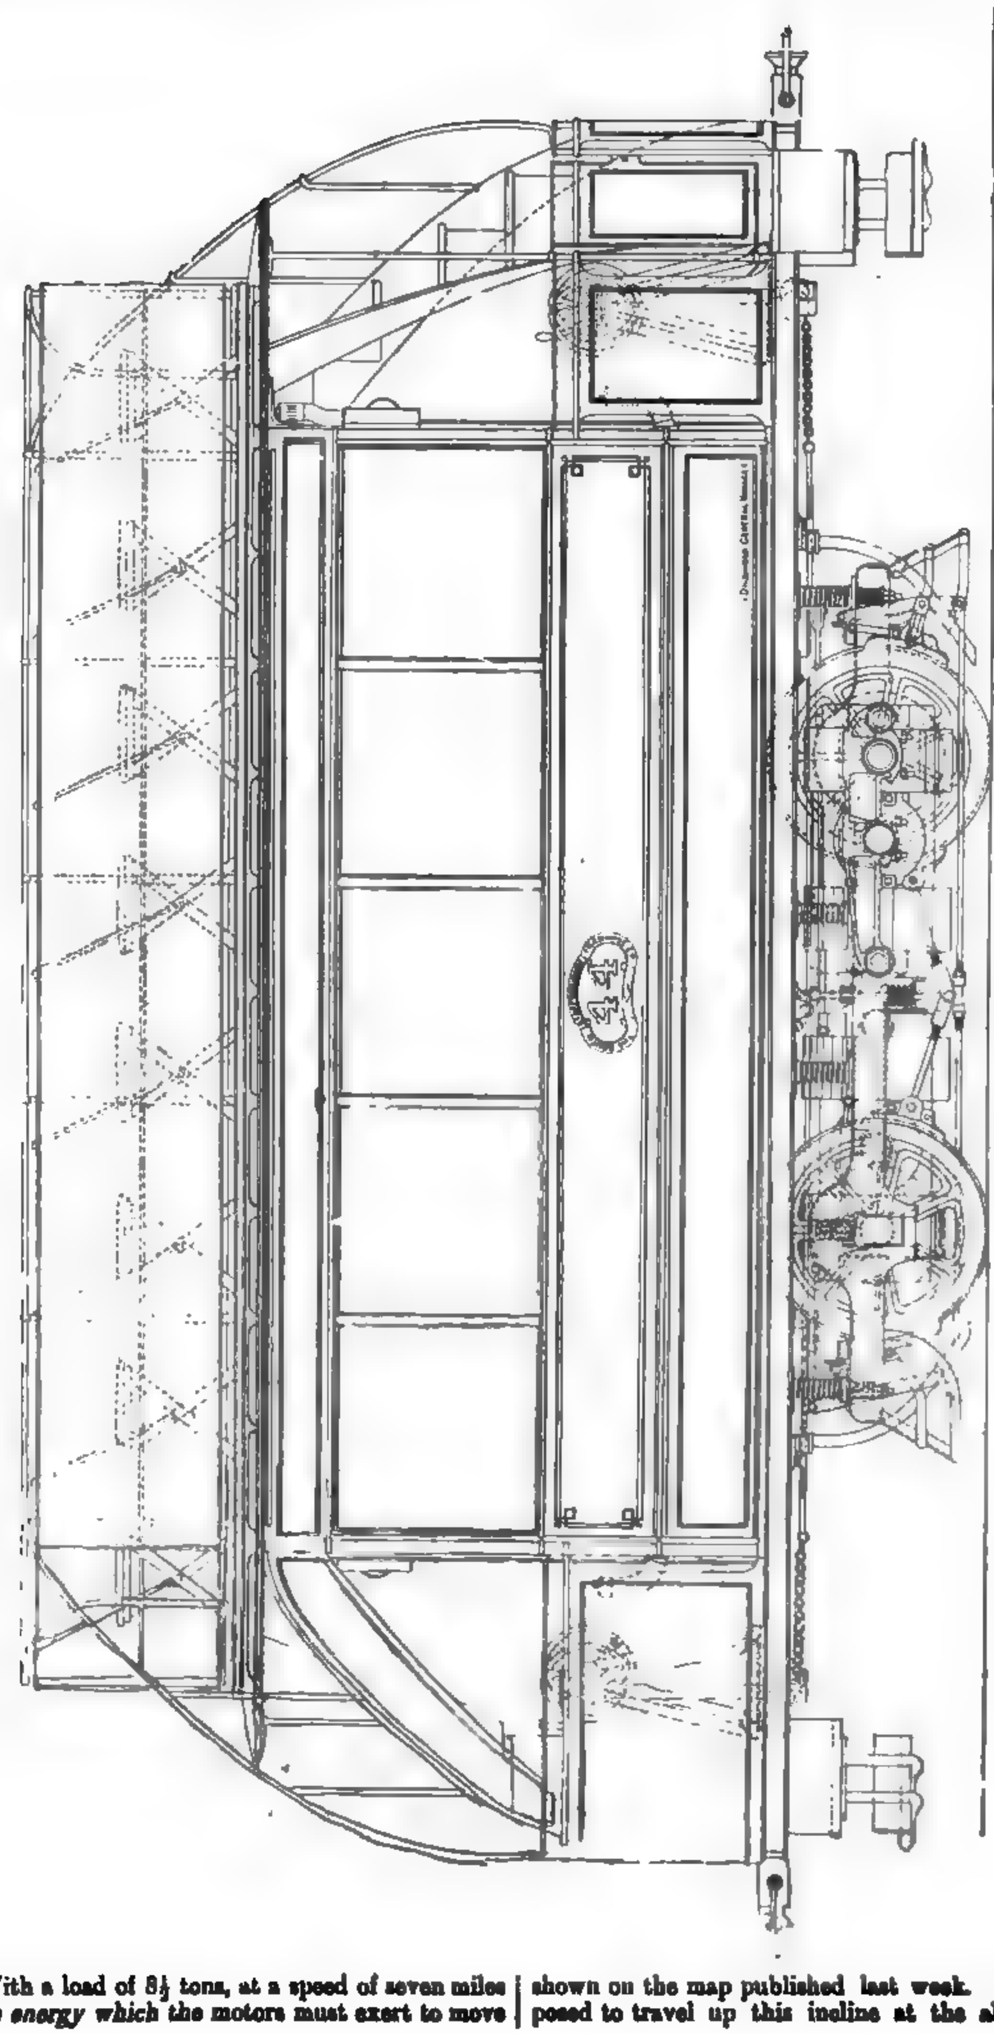
nd Elevation, Showing Cars Passing, with Range of Side Movement of Trolley Poles.

The necessary switch and brake handles are fitted to the car in duplicate—one set at each end—so that the driver, or "motorneer," in reversing the car for a return journey has nothing to do but pass from one end to the other.

Two motors are employed for each car, and the switch arrangements not only allow these to be coupled in series or parallel for starting and when under way, but also serve to vary the field magnet circuits and thus enable the speed to be regulated over a wide range. Single helical gear is employed, with cast-steel wheels 1ft. 9in. diameter. The pinions measure 6in. in diameter. At a speed of seven miles per hour the car axles go round about 70 times per minute, so that the motor speed is not more than 250 revolutions per minute. The motor frames are suspended in a similar fashion to that now usually adopted—that is, with bearings at one end upon the car axle, whilst the other end is hung by powerful springs from a beam running across the centre of the car frame.

Taking an average amount of 30lb. per ton as " tractive force required for an ordinary tramcar to overcome

the line-resistance, it is interesting to note the power necessary on this line to move the cars, apart from questions of gradient. With a load of 8½ tons, at a speed of seven miles [an] hour, the energy which the motors must exert to move each car on the level is approximately 5 h.p. The steepest gradient on the line is a short length of 1 in 16, as shown on the map published last week. If a car be supposed to travel up this incline at the above speed, fully



SIDE ELEVATION

View showing Brake and Motor Gear

loaded, the motors would be called upon to exert no less than 22 h.p. in addition, or a total of 27 h.p. As a matter of fact, the same speed is, of course, not kept up when ascending a gradient as on the level; but the figures given serve very well to emphasise the great range of power required for traction effort, not only in starting the cars, but also in overcoming the influence of gravity.

whole joint being then tinned. The rivets pass, with a drive fit, through holes drilled in the rail ends, and are then closed over with heavy hand hammers.

The same rails used for steam traction will serve for the electric cars; the section is shown in an accompanying illustration. They have been put down in 30ft. lengths, and weigh 75lb. per yard, being 6in. in depth. Flat iron

End View of Car Showing One Motor and Gear.

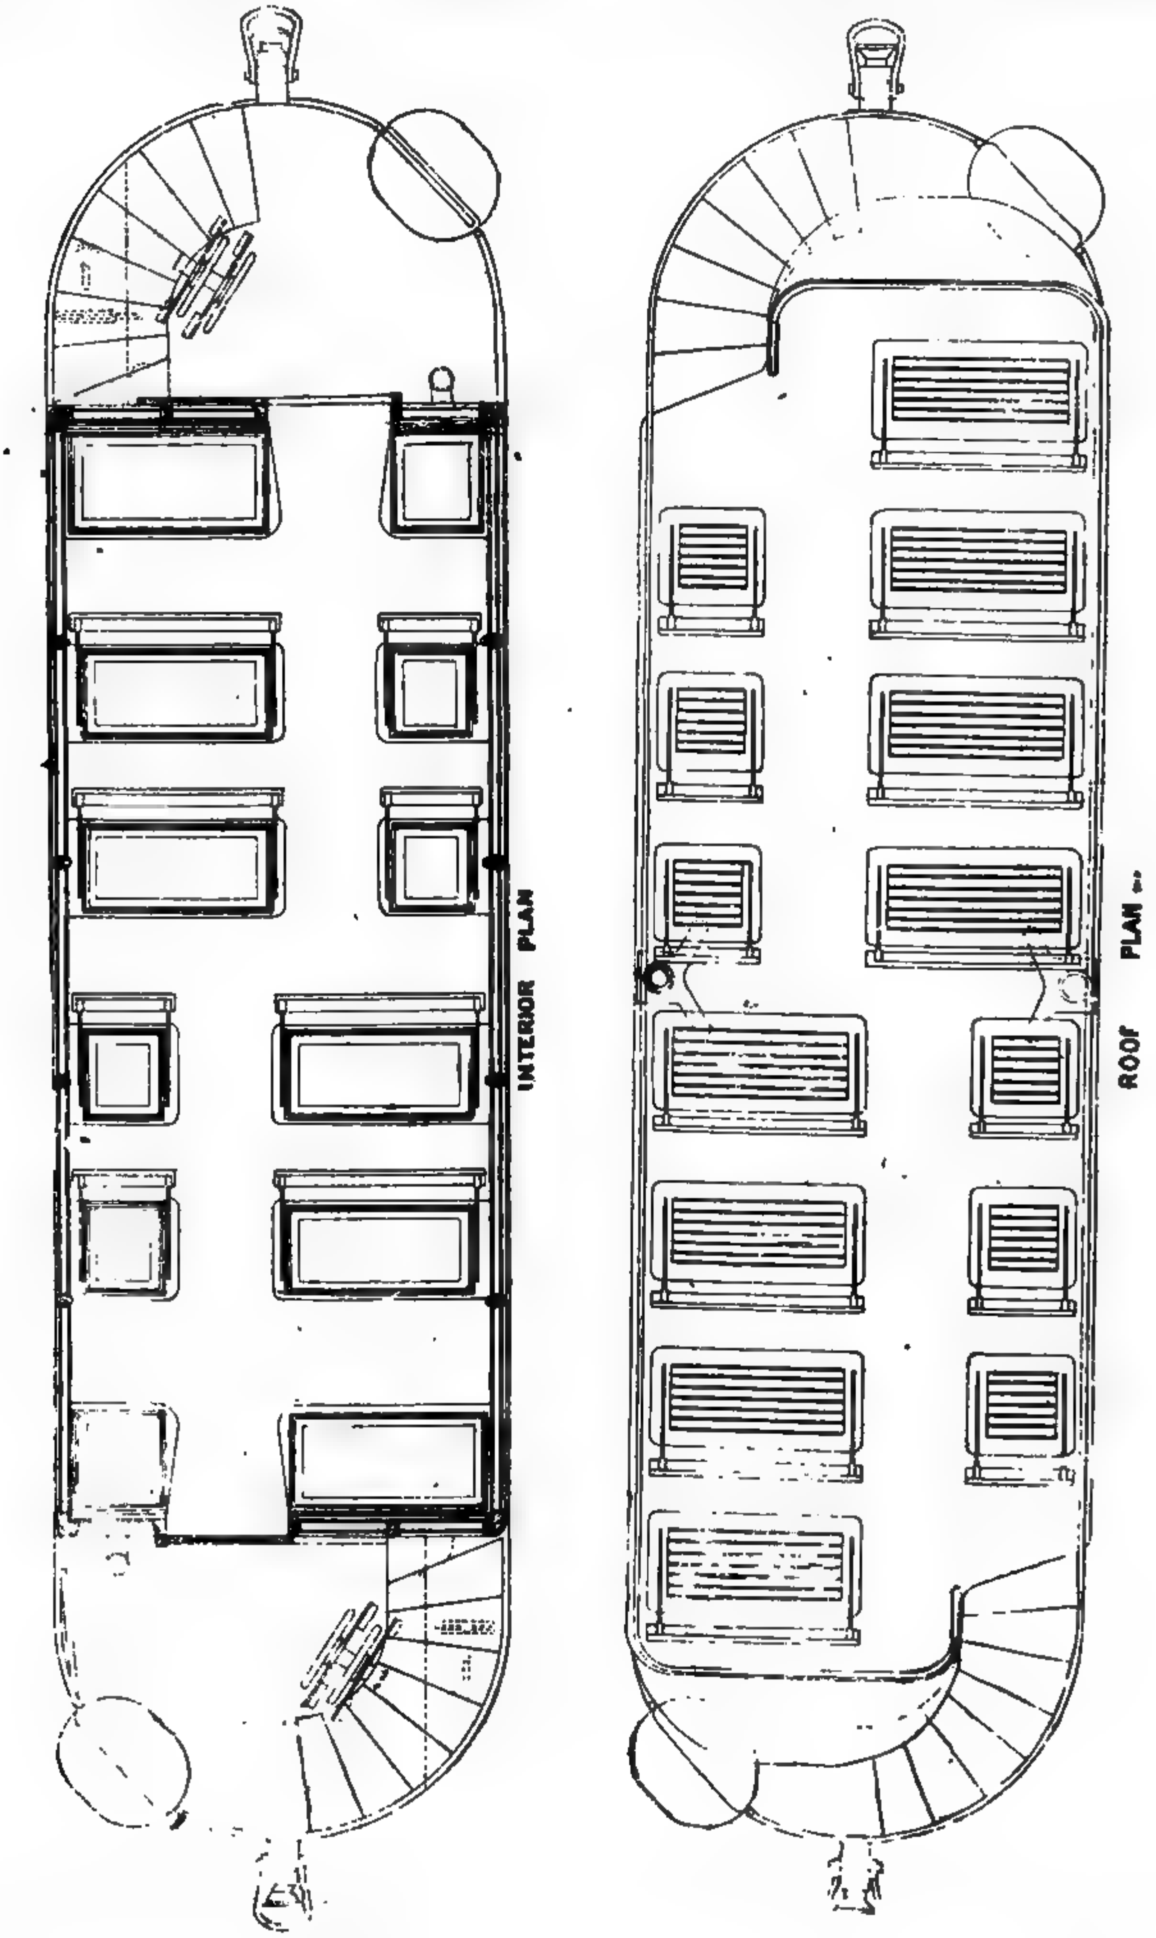
There are not many details to be given of especial interest in connection with the line or permanent way itself. Considerable expense has, of course, been necessary in putting down rail bonds in order to secure as efficient an earth return as possible, but apart from this no structural changes have been required for the new system of working. The rail bonds consist of stout copper wire in 2ft. lengths; to each end of one length is soldered a soft iron rivet, the

ties, 1½in. by ½in., rounded and screwed ¾in. at each end, are fixed every 8ft., and serve to keep the gauge true. The rail bed or foundation is, of course, built of concrete in the usual style, one heavy 6in. layer sufficing for the purpose.

Every precaution has been taken by the contractors to secure efficient and reliable work; and they are to be congratulated upon the results so far shown. As an instance of the care taken to prevent stoppage of traffic, it may be

nentioned that the whole system of overhead conductors s arranged in short sections, so that if anything should go

The whole of the electrical and station equipment has been in the hands of the Electric Construction Corporation,



The New Electric Tramcars on the South Staffordshire Tramway.

wrong with one of these, it may at once be cut off whilst repairs are being effected, without at the same time interfering with the traffic elsewhere.

whose energetic manager, Mr. T. Parker, has found this line a splendid source of opportunities for exercising his well-known and able ingenuity in overcoming obstacles.

The Corporation, besides supplying all the electrical plant, has entered into a contract with the Tramway Company to work the system for five years at a fixed mileage rate,

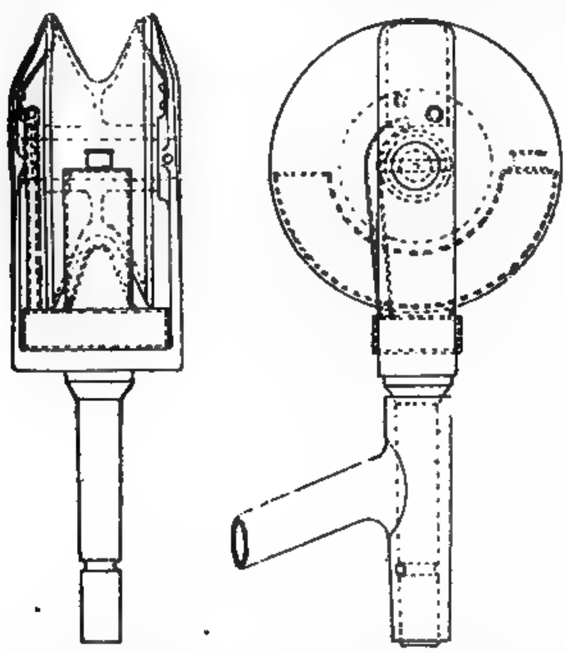
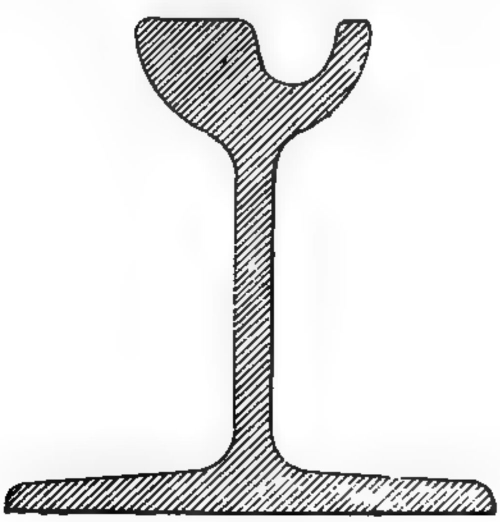
inclusive of maintenance. Mr. E. Parker has represented the Construction Corporation on the contract as resident engineer.



The Trolley.

Not the smallest part of the credit, however, by any means is due to Mr. Alfred Dickinson, C.E., the Tramway



Section of Tram Rail.

Company's general manager, who has provided the designs, plans, and specifications throughout, and superintended the conversion of the concern from one system to the other. Indeed, the special features which have been already indicated as forming the essence of novelty in this electric system are, it is stated, almost entirely due to Mr. Dickinson, and he must therefore be credited with showing tramway engineers in general how they may most advantageously introduce electric traction on their lines without trespassing in any possible degree upon the well-known prejudices of the British public.

ELECTRO-HARMONIC SOCIETY.

The next concert of the above society will be a ladies night, and will take place on Friday, November 25, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock. Artistes: The Queen Vocal Quartette, Miss Mina Rees, Miss Mary Hutton, Miss Amy Sargent, Miss Lucie Johnstone; violoncello, Mr. Clement Hann; pianist, Mr. Alfred E. Izard; humourist, Mr. F. Upton; musical directors, Mr. T. E. Gatehouse and Mr. Alfred Izard. A Bechstein concert grand pianoforte will be used:

PROGRAMME—Part I.

Quartette .... "Legends" .... Mohrling
Queen Vocal Quartette.

Song .... "Il Bacio" .... Arditi
Miss Mina Rees.

Violoncello solo .... (a) "Reverie" .... —
(b) "Tarantelle" .... Poppin
Mr. Clement Hann.

Quartette .... "The Banks of Allan Water" Specially arranged
Queen Vocal Quartette.

Pianoforte solo .... "Polonaise" .... Lizt
Mr. Alfred Izard.

Song .... "Voices in the Heart" .... Slaughter
Miss Mary Hutton.

Quartette .... "The Old Folks at Home," Specially arranged.
Queen Vocal Quartette.

Sensation novel .... "The Tragedy" .... Upton.
Mr. F. Upton.

PART II.

Duet (violoncello and pianoforte) "Variations, Op. 17" .... Mendelssohn.
Mr. Clement Hann and Mr. Alfred Izard.

Song .... "One Word" .... Pinsuti.
Miss Amy Sargent.

Duet .... "Friendship" .... Marziale
Miss Mary Hutton and Miss Lucie Johnstone.

Violoncello solo .... (a) "Intermezzo" .... Mascagni

Mr. F. Upton.

THE INSTITUTION.

SIR,—If the Council of the Institute is to be changed so as to more nearly represent the actual membership, may I suggest that provincial members should have two or three seats? I am well aware of the difficulties attending the proper service of a provincial member of Council, and that the actual work of the Institution must be done by local members; but nearly all provincial members come to town more or less frequently during the season, and it would not usually be difficult for them to attend some meetings of the Council. Probably, too, the consciousness of having a duty to perform would make most men come up more often. If such a course was adopted, and we in the provinces were represented by a few strong members who would not mind taking a little trouble on behalf of their constituents, I imagine that the great complaint raised in my article—that of the persistent neglect of everyone not resident in London—would soon disappear.—Yours, etc.,

SYDNEY F. W[illegible]

THE

ELECTRICAL ENGINEER.

SPECIFICATIONS.

It is becoming necessary to direct close attention, not only to the successes of electrical engineers but also to their failings. For a time people have to be satisfied during the development of a new industry with the results of imperfect knowledge, but as time passes onwards they expect improvement. In the question of proper specifications we fear that on the whole there is no improvement, that the matter and method of the clauses cannot be for a moment considered satisfactory. The fault is one that might have been, and indeed was foreseen. Even yet the general public make no distinction between an electrical engineer and an electrician. They go to the latter when they ought to go to the former. Experience will open their eyes to the difference, but then experience is usually gained too late. We are on the eve of many central stations being designed and built. The course to be pursued, which we have strenuously advocated, and which we believe is the only good one, is for the local authority to employ the *best* available consulting engineer just as it would for waterworks or sewage schemes. Instead of doing this, however, too many are under the glamour of a name. To them the man who calls himself an electrical engineer is assumed to be one, and a competent one. Terms are asked for, and while *the* competent man requires a fee commensurate with his knowledge and abilities, the incompetent man asks for what he thinks will tempt the querist to employ him, and is frequently employed accordingly. That is a fatal mistake. The incompetent man is filled to repletion with a jargon of technical terms—especially electric—which have little or no bearing upon the matter in hand. He has to design a central station, and not talk to a class of boys. The electrical engineer must, if competent, be a good mechanical engineer. The central station, if it is to work properly and be maintained economically, must be properly equipped both mechanically and electrically; in fact, we imagine the more important part economically is the mechanical. Still, there is hardly a detail either mechanical or electrical which is not essential to economical maintenance, and which, therefore, if ill-designed has a bad effect upon the whole installation. These considerations mean that the designer should have a thorough knowledge of each branch of the work; should carefully design each detail so that no weak point appeared. This brings us to the drafting of the specification. In the great majority of instances clauses now appear that this or that part of the apparatus is to be supplied to the satisfaction of the engineer. Any clause of that kind is a proof positive that the specification is from the hands of an incompetent man. The materials required, the apparatus wanted, in every detail should be clearly and specifically described. Nothing should be left to chance or to the contractor's whim. We have pointed out again and again that tenders sent in by contractors who each specifies his own particular system cannot be compared satisfactorily by any human being: there is no common ground of comparison, and the user is in the same position as the man who goes to half-a-dozen builders and says "What

will you build me a house for after your own design? The man, in the first place, has no proof that the design will be appropriate to the position or for his requirements, especially if he gives his order to the tender which appears lowest. We say appears advisedly, because it often happens that the tender which appears lowest, in reality in the long run is far from being so. But there is justly as much adverse criticism from the contractor's side at these badly-drawn specifications as there is from our point of view. When the decision is left to the contractor, if he has a reputation he immediately puts aside all ideas of cheap and nasty, and estimates for proper work and excellent materials; if, on the other hand, he has no reputation, and is merely running after work at any price, he estimates for the cheapest materials regardless of how long they will last without costly repairs. The maintenance is not his look out. The designer knows or cares nothing about the future, therefore the tendency is to legislate for the present only. Again, there may be various apparatuses fulfilling the same or similar functions. The designer who specifies at random, or leaves it to the contractor, probably does not know much about the apparatus; hence one contractor may estimate for the proper apparatus, another for the cheapest, trusting to the ignorance of the engineer to pass the estimate. A few hundred pounds of difference is soon made up in such ways, and we are bound to state that the best contractors are and must be the greatest sufferers from badly-drawn specifications.

SOUTH STAFFORDSHIRE TRAMWAYS.

There are many reasons why we should direct attention to the South Staffordshire electrical tramway system. In the first place, it is the first English attempt to instal an overhead system. We are, of course, well aware of what has been done at Leeds, but that work was due to the enterprise and energy of an American house. In the second place, the design of the South Staffordshire system is no mere plagiarism of the overhead system so largely employed in America, but is in numberless points original. Generally, when an overhead system is used, poles are erected on both sides of the street with a trolley wire in the centre, but Mr. Dickinson has designed this with only one set of poles on one side of the road, which enables passengers to be carried on as well as in the cars. The technical details are, however, set forth elsewhere, and we think all who read them will agree with General Hutchinson in congratulating Mr. Dickinson and Mr. Parker for the successful manner in which they seem to have designed and carried out the whole of the work. As would be gathered from the plan of the district given in our last issue, its centre is Walsall. The whole of the South Staffordshire system is not equipped with electrical plant. The company has some twenty-three miles of line, and has long used steam traction, which, however, was not liked by the inhabitants, nor found cheap enough for the company. Hence the value of electricity was examined, and before consent was given for its use, the authorities of the district made exhaustive enquiries as to its suitability. Mr. F. Brown the electrical engineer to the Walsall Corporation went to America and reported on the electrical lines there. Reference to this report will be found in our issues of July 17th and 24th last year. A deputation of the Council visited Leeds to examine for themselves. Mr. Dickinson, no doubt to allay criticisms, suggested the possibility of using one set of poles only on one side through the streets, and has, as we have said, very ingeniously carried this out. The consent was given, and a start was made to equip about nine miles of line. The district the new system runs through is essentially a manufacturing one, and includes Walsall, Darlaston, Wednesbury, and Bloxwich. The population of Darlaston is 15,000. The principal articles made here are bolts and nuts, all kinds of screws, railway fastenings and general ironwork, roofs, bridges and girders, all kinds of wrought and cast ironwork, shoe tips, files, latches, wire gauges, and gunlocks. There are also malt kilns and brick-fields, and several extensive ironstone and coal pits, with an abundant supply of the valuable ore known as "blue flats." Walsall, which includes Bloxwich, is a municipal, parliamentary, and county borough, with a population of 72,000. Coal mines, quarries of limestone, ironstone and clay pits, are numerous. Among the manufactures for which it is noted may be enumerated saddlers' and coach ironmongery, buckles, chains, curbs, bits, spurs and stirrups with plated and other mountings, bridles, saddles, harness collars, and all the necessary trappings for horses and carriages; also locks, bolts, keys, pulleys, brushes, and spectacles. There are also a number of brass and iron foundries, iron, galvanised iron, and iron-tube works, several corn mills and tanneries, besides establishments for the currying, dyeing, and polishing of hides for the staple commodity of harnessware. Walsall is also known far and wide as the town in which "Sister Dora," the devoted nurse of sick folk, lived and died, and whose beautiful statue adorns the open square in the centre of the town. It is also not without historical interest. Queen Elizabeth, in one of her tours, affixed the Royal seal and signature at Walsall, or, as some say, whilst she was staying at the Manor House of Bescot on July 13 in the twenty-eighth year of her reign, to a deed preserved in the archives of the Corporation granting a deed of land to the town. In 1643 Henrietta Maria, Queen of Charles I., remained here for a short time, and is said to have stayed at The White Hart hostelry previous to joining the King at Edgehill.

Wednesbury, popularly known as Wedgebury, is a municipal and parliamentary borough and market town of considerable antiquity. The population of the parish in 1881 was 24,566. Its manufactures are numerous and important, the principal being rails, boiler-plates, bar iron, Bessemer steel, Siemens-Martin steel, railway carriage axles, general iron-work for railways, gas, water, and steam tubes, spades, shovels, and edge tools, gunlocks, coach springs, hinges, bolts and nuts, and wrought iron of every description. There are also stoneware potteries. An abundance of coal is found here, as well as iron ore, limestone, clay (both potter's and brick), and a kind of coal which, from the intense

heat it gives out, is admirably adapted for the forge. From this it will be seen that the traffic must necessarily be considerable, and, in fact, the company carries annually about four million passengers, a large proportion of which travel on that portion now to be served electrically. The Board of Trade inspection by Major-General Hutchinson and Major Cardew last Saturday was a great success, and led to the congratulations of General Hutchinson to the engineers for having brought the installation to such a successful issue.

INSTITUTION OF ELECTRICAL ENGINEERS, Nov. 17.

The President, Prof. Ayrton, F.R.S., in the chair.

The following candidates were in due course balloted for and elected members of the Institution:

Foreign Members.—C. E. L. Brown, Baden, Switzerland; M. A. van der Sprong, assistant inspector, Dutch Indian Government Telegraphs, Batavia.

Associates.—Harold A. Clegg, 9, South parade, Manchester; William Corkhill, care of Messrs. Turner, Morrison, and Co., Asiatic Steam Navigation Company, Calcutta, India; Edward Henry Draper, Eastern Telegraph Company, 50, Old Broad street, E.C.; Edward Somerset Eccles, Tower House, The Hoe, Plymouth; Arthur H. M. Francis, 16, Fleet street, Dublin; Charles Jones, 42, Waterloo road North, Wolverhampton; Francis Hastings Medhurst, 2, Sidney street, Cambridge; Thomas Oddy, River street, Rochdale; Edward T. Parker, Newbridge House, Wolverhampton; H. Faraday Proctor, Moor View, Newcastle-on-Tyne; William Sillery, Wrexham; John Edwin Teague, Providence Wharf, Vauxhall, S.E.; Howard B. Trotter, 176, Adelaide road, N.W.; Archibald Wilson, 18, Warriston crescent, Edinburgh; Herbert Wooler, 34, Hall lane, Farnworth, near Bolton.

Students.—John George Barchell, Meadowhurst, Woodside lane, North Finchley; Frank Farley, The Law Courts Branch Bank of England, E.C.; Frederic Digby Latimer, 130, [illegible] street, E.C.; Hugh Berno Player, "The Wern," Ystalyfera; Charles Henry Stobart, St. Augustine's Vicarage, Bermondsey; Charles Barnard Wigg, 18, De Crespigny park, Denmark hill, S.E.

The discussion on Mr. Swinburne's paper, "The Problems of Commercial Electrolysis," was then continued by Mr. **Addenbrooke**, who stated that for the last two years he had devoted a great deal of time to the alloys and utilisation of aluminium. He agreed with Mr. Swinburne. The companies keep their processes secret as far as possible, and the demand is greater than the supply. There are [illegible] of processes to supersede the electrolytic processes. He thought that within 25 years aluminium would be as cheap as copper, and from its electrical properties it should be should be largely used in electrical work, such as for tramways. It would be well to watch the course of experiments.

Mr. Lloyd referred to the great interest of the paper, and added to Mr. Swinburne's list the work of electroplating. Cobalt, as stated by Prof. S. Thompson, is deposited in an easy manner, but to the speaker the greatest interest was in the deposition of alloys. This was a distinct advance, especially the deposition of silver alloys. By using alloys in Sheffield instead of silver, he calculated nearly £5,000 per year would be saved, in fact, more because of indirect savings. He called attention to samples of alloy of silver and cadmium. The latter is small in quantity, but the metal is improved, and it is difficult to find any difference in colour from pure silver. In depositing simple metals there was little for the electrician to do, but the secondary actions with alloys were very interesting and need careful attention. A sample of brass deposit, as also of palladium, was noticed. The latter was not oxidisable, and the plated material would stand a very high temperature without peeling. The palladium plating had been tried with the arc and stood successfully.

Mr Bevan referred to observations of Mr. Faulkner relating to chlorates, and said that the magnesium chlorate was found if the conditions were favourable and not otherwise. In connection with the paper, Mr. Swinburne takes the cost of power at ½d. per kilowatt, and the speaker thought this was a satisfactory figure, and not, as some speakers thought, too low. It was hardly fair to compare the price of oxygen obtained by oxygen [illegible] electrolytically and by the Brin process. In electrolysing sodium chloride from 4 volts to 4½ volts was an economical pressure. The strength of solution was important, and the speaker did not agree with Mr. Swinburne's comparison with those in the evaporation of the caustic liquor. He agreed with Mr. Swinburne as to the anodes, that Greenwood's anode would stand the wear and tear. He disagreed with Mr. Swinburne as to the influence of the salt upon the caustic soda. The results obtained in his experiments were recorded in the *Journal* of the Society of Chemical Industry.

Mr Trotter thought that some of Mr. Swinburne's examples were rather of electro-chemistry than electrolysis, and though he could not suggest a theory for electric tanning accepted as most probable that of Chastaing. (Practical tanners say that electric tanning is pure and unmitigated nonsense, and the failure of all [illegible] anywhere seems to point to this conclusion as a [illegible] one.—*Ed. E.E.*) He referred to his experiments on the [illegible] painting, and that not any [illegible] process however good on paper must also be exceptionally good in the laboratory.

Mr Andreoli jun., referred to the anodes, and the [illegible] anodes that had been used, and to Harold's experiments [illegible] on the density of solution, the carbon being less [illegible] the denser solutions. Electrolytic bleaching had not [illegible] [illegible] to a great extent, it had been [illegible]. He [illegible] many of the difficulties, but said the [illegible] was the production of chlorine and caustic alkali. [illegible] simplified the problem, and allowed denser solution to be used, the only difficulty being that hydrogen is separated by [illegible] and an explosive mixture is formed.

Mr Cooper, answering Mr. Andreoli, granted that there [illegible] been difficulties such as mentioned, which in the Hermite [illegible] had been got over years ago. At the present moment on the Continent they were replacing in paper and other [illegible] to 3,000 tons of bleaching powder per annum. As to [illegible] would be pleased to show those interested the figures, [illegible] showed in cases where water power, reckoned as costing [illegible], was used, a saving of 50 per cent., and where steam [illegible] used, reckoning £[illegible] for 1 h.p. for 24 hours, a saving of [illegible] per cent.

Mr Blunt referred to the electrolytic extraction of [illegible] hopeful, but it would be still more hopeful when [illegible] would be treated directly. Mr. Swinburne had [illegible] the Hoffner process, and wondered why the chloride was [illegible] to the sulphide. The reason was that chlorides were [illegible] and easily formed than sulphides, and the sulphur was [illegible] left free. It seemed to the speaker that the greatest difficulty was in the anode [illegible] to stand. The latest [illegible] [illegible], but its value was not yet [illegible]. He had found Greenwood's anode fairly satisfactory, but [illegible] only tried it experimentally.

Mr J. W. Swan had sent a communication, in which [illegible] pointed out that in estimating the kilowatt hour, the [illegible] used was not mentioned. [illegible] to electro-deposition, but in face of the [illegible] tion of placing large plates in the Siemens [illegible] no longer [illegible]. He had found that aluminium [illegible] deposited when getting [illegible] per square foot [illegible] at the rate of 1 gramme per sq. ft., and with [illegible]. With reference to extraction of zinc [illegible] there might be great improvement in present zinc smelting. [illegible] was a great waste of both coal and metal, resulting in a [illegible] 20 to 30 per cent. Among [illegible] processes, [illegible] has not been [illegible] of soda.

Mr Mordey [illegible] that in a class experiment [illegible] when [illegible] had been given off. He [illegible] effect mentioned [illegible] authorities, but it was [illegible] Faraday [illegible], 1834 *Researches*, vol. i., para. [illegible].

Mr Richardson agreed with Mr. Andreoli that [illegible] of [illegible] to density of solution [illegible] deleterious chemical actions were avoided with [illegible] solutions. In bleaching, it is not the chlorine directly that is material; it is oxygen that acts. [illegible] electrolysis it was the secondary action that [illegible]. He thought hypochlorite solutions would not pay [illegible] special circumstances.

Mr Faulkner did not agree with Mr. Andreoli, but [illegible] to be better than anticipation. If platinum anodes were [illegible] then [illegible] were better.

The **President** referred to Mr. Mordey's experiment [illegible] allowed was important, if electrolytic; in fact, it pointed to direct obtaining of current by burning carbon. [illegible] had been made to electric transfer as supposed to exist in electric tanning.

Mr Sinclair disagreed with the estimate of ½d. per kilowatt hour, and thought ¾d. would be nearer. An anode [illegible] good but would not last. For a good anode there was an [illegible] limited future.

Mr Swinburne, replying, said he was pleased to see [illegible] eminent chemists present. With regard to cost he had taken a plant of 1,000 h.p., coal at 10s. a ton; he had allowed 2lb. of coal per indicated horse-power; a 1,000 h.p. [illegible] showed [illegible] would. He had taken combined efficiency of engine and dynamo at 85 per cent., which could [illegible] cost less than £[illegible] h.p., or, and [illegible] £700, and [illegible] Willans engines at [illegible], and [illegible] at [illegible] per cent. and depreciation at [illegible] per cent., running night and day. The [illegible] came to £[illegible], which was [illegible] ½d. per kilowatt hour. He had stated that wide allowance should be made in practice. He knew some firms were going ahead with electrolysis [illegible] referring, but as his paper had not been [illegible] on [illegible] papers he thought chemists did not recognise the [illegible]. He had not referred to Mr. Swan's process as his paper was already written. The deposition of aluminium would be [illegible] [illegible] current was expended. He had [illegible] [illegible] tanning and [illegible], which was [illegible] to be [illegible] by [illegible]. He [illegible].

A vote of thanks was accorded to Mr. Swinburne for his important paper.

The **President** announced that Mr. David Salomons had [illegible] at the position as temporary hon. treasurer in place of [illegible] [illegible].

The meeting was adjourned to next Thursday, when a paper will be read by Dr. Fleming on "Experimental [illegible] on Alternate Current Transformers."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COMMERCIAL ELECTROLYSIS.

SIR,—In your issue of last week you gave a short report of the remarks made by myself at the meeting of the Institution of Electrical Engineers last Thursday.

I shall be obliged if you will allow me space to correct two slight inaccuracies in that report. I stated that an ordinary "electrolyser" as used in the "Hermite" process was worked at five volts and 1,000 amperes. Your report puts it the other way round, and it must have struck your readers that Mr. Rawson's anticipation of leakage would very likely be realised. The second point was regarding the renewal of platinum anodes. I stated that an installation of 10 electrolysers working continuously for five or six years, only one set (consisting of 52 plates) of new ones was supplied, the plates being distributed among 10 machines.—Yours, etc., CHARLES F. COOPER.

3, Princes-mansions, S.W., Nov. 15, 1892.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

SIR,—If I take up my pen to comment upon the manifesto of Messrs. Erskine, Manville, Mavor, Raworth, and Swinton respecting the composition of the Council of the Institution of Electrical Engineers, it is not at all to formulate any reply to the indictment framed by these good men and true. I merely wish to complete their statement which, it is well known, embodies partially sentiments that exist pretty widely in the Institution, within the Council as well as without. In other words, there are members of the Council who as individuals recognise, perhaps even more clearly than do Messrs. Erskine, Manville, Mavor, Raworth, and Swinton, the shortcomings which they have in part pointed out. As it is, in the natural course of things, my turn to retire from the Council in six weeks' time, I can speak the more impersonally. The object dear at heart to the memorialists can, therefore, in one instance, be readily attained without friction.

Let me first begin by classifying a little more definitely the membership of the Council (I take the official list, as the memorialists did; but, alas! we have just lost Mr. Graves). As the term electrical engineer has no legal or recognised definition, and as every gasfitter is nowadays an electrician, I avoid these indescriptive terms. In passing, I remark how strange it is that the memorialists are able to discover no fewer than 10 professors who are neither "electricians" nor "electrical engineers." Perhaps Prof. Hughes never was an electrician in spite of his well-known inventions. Perhaps Prof. Hopkinson never was an electrical engineer. But in that case—dreadful thought—who is? However, let that pass.

The Council, including past-presidents and vice-presidents, consists, indeed, of the following:

Manufacturers and contractors	5
Telegraph, telephone, and cable men	13
Chemists	2
Engineers in consulting practice not included in above	6
Baronets	1
Engineers to manufacturing firms	1
Government officials not included in above	2
Teachers of electricity not included in above	2
	32

or, omitting past-presidents and vice-presidents:

Manufacturers and contractors	2
Telegraph, telephone, and cable men	5
Chemists	0
Engineers in consulting practice not included in above	5
Baronets	0
Engineers to manufacturing firms	1
Government officials not included in above	2
Teachers of electricity not included in the above	0
	15

Inspection of these figures at once shows on what head the Council is overweighted. But, then, the Institution must be forgiven for the circumstance that it originated as a body of telegraph engineers, and not as a body of manufacturers or contractors.

But really there is a grain of reason in the contention that there are in the Institution and on its Council gentlemen "only indirectly connected with practical engineering." Too often the phrase "practical engineer" is held to denote one who has served seven years of drudgery at the bench. Well, but that is precisely (my friends will pardon me for so personally using them as examples) what my friend John Perry, engineer and professor, did; it is precisely what my friend William M. Mordey, engineer and inventor, did not do. It is within the bounds of possibility that there may be contractors and manufacturers who are even less directly connected with practical engineering.

It is a pity for the memorialists' case that they have so sadly understated the "professorial element" on the Council. Their delicately-concealed suggestion that if a man has at some time or other held a responsible post as a teacher, that circumstance in some way disqualifies him to take part in managing a "professional" body such as the Institution, reaches more widely than to the 10 "professors" (including Lord Kelvin) so denominated in the official list of the Council. To these 10 should be added Prof. Sir Frederick Abel, Prof. John Hopkinson, Prof. (now General) Webber, and Prof. Crookes, not to add Mr. Mordey and Mr. Swinburne, both of whom have qualified themselves for the same courtesy by systematic teaching. So the 10 should be written 16. It is evidently high time that the number of "professors" on the Council should be reduced. There is also an undue proportion of members of Council whose names begin with the letter C. Moreover, compared with the Civil Engineers, there is a smaller proportion of "Sirs" on the Council. This is a sad oversight which might be commended to the notice of the P.M.G. (I do not mean the *Pall Mall Gazette*.)

What seems to be the saddest fault of all, is the complete absence from the Council of any member who, being neither an engineer in consulting practice, a teacher, a soldier, a sailor, an officer in the volunteers, a Government official, a company director, a company promoter, a cable man, a telegraph operator, a chemist, an author, a a peer, or a baronet, and never having been any one of these things, shall be therefore competent to represent "those actively engaged in constructive work." The omission is not, however, irremediable. Doubtless the Council, awakened at last to a sense of its shortcomings, will fill one of the shortly vacant places by the member entitled to such unique distinction—if he can be found.—Yours, etc.,

SILVANUS P. THOMPSON.

THE ELECTROMAGNETIC THEORY OF LIGHT.*

BY JAMES H. GRAY, M.A., B.SC., PRESIDENT.

(Concluded from page 473.)

Coming to the case of other dielectrics than air, we must have $\frac{1}{\sqrt{K\mu}}$ = velocity of light in the dielectric, but the velocity of light varies with the wave-lengths; in other words, there is dispersion, and we meet with the great difficulty that is as yet not completely explained by any optical theory. If we are to explain dispersion, we must assume that either K or μ, or Kμ, varies with the length of the waves. In order, therefore, to get a fair comparison, we must take electromagnetic waves and light-waves of as nearly the same length as possible. Now, the highest frequency of vibration for which K has been measured is 25 millions per second. In the electrostatic system of measurement we have $\mu = \frac{1}{v^2}$ for air, and practically so for glass and other dielectrics, $\therefore \frac{v}{\sqrt{K}} = v^1$ the velocity of light in glass. But $\frac{v^1}{v} = \frac{1}{k}$ where k is the index of refraction of glass. Therefore $\sqrt{K} = k$. Prof. J. J. Thomson (*Proceedings* Royal Society, June 20, 1889), and Blondlot (*Comptes Rendus*, May 11, 1891) found that $\sqrt{K}$ approximated to k for a frequency of 25 millions per second. Dr. John Hopkinson (*Phil.*

* Presidential address delivered before the Physical Society of Glasgow University.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

V.—WATER POWER.

(Continued from page 447.)

This is a source of power that exists to a very limited extent in England, because the rivers are not of a rapid nature, and there are very few waterfalls of any size. In a country like Switzerland water power is abundant, due to the swift mountain torrents and waterfalls that are met with everywhere. It is, therefore, only natural that the Swiss engineers are famous for the turbines manufactured by them, and their experience in utilising this source of power. Water power, for motive purposes, is used all over the world whenever it can be obtained and proves a most valuable and cheap source of power where coal or any such fuel is scarce and expensive. The development and practical application of transmission of power by electricity has made a good source of water power of still greater importance and value, since by electricity the energy of the water, instead of running to waste, can be transmitted a number of miles and there utilised, subject to a loss depending on the distance and the method employed. This matter will be discussed later on in the chapter relating to "Electric Transmission of Power." For the present water power will be simply referred to in a brief way as a source of motive power.

A moving body of water may be said to deliver its power in two general ways, in a practical sense: first, by momentum; second, by weight. A rapid stream explains the first, a waterfall explains the second. All water motors may be divided into two classes: (I.) Waterwheels (horizontal axis), (II.) turbines (vertical axis).

(I.) *Waterwheels.*—This class of water motor may be again divided into three types, namely, (*a*) undershot, (*b*) overshot, (*c*) breast.

The undershot waterwheel is the oldest form of any device used to obtain power from a moving body of water. Figs. 1 and 2 show an undershot wheel. The water flows in what is named a "race," the part in front of the wheel being called the "head race," whilst the part behind the wheel is called the "tail race." In the head race the water is flowing at its normal rate, and so is in a condition to do work. Upon reaching the wheel, which offers an obstruction, the water forces the floats in front of it, and so turns the wheels; the water now has parted with more or less of its power, and so continues its way at a slow rate into the tail race. The shaft of the wheel, which is of wood, is encircled by an iron socket fastened to it by wooden pins. The radial arms are set in the socket and fastened with bolts. An iron ring is fixed on and supported by these arms, the ring being in segments, each segment being fastened to its corresponding arm by iron bands; the segments are also joined together by iron bands.

The floats are pieces of board, about 1in. to 1½in. thick; these have the same width as the rim of the wheel, and are supported by stout wedges of wood placed behind them. The diameter of the wheel determines the number of arms. With a diameter of, say, 12ft., there would be about six arms, the floats being placed about 15in. apart. That portion of the race just underneath the wheel is curved out, so as to fit the wheel, the race being made the same breadth as the wheel. The average depth of water should be about 7in. or 8in., and this depth is regulated by a gate, fixed in a slanting position; by raising or lowering this gate, a greater or less quantity of water can be admitted through the open space between the bottom of the gate and the bed of the race. The angle of slant for this gate must be such that there is a very small distance between the opening and the tips of the floats. By this means the water impinges right on to the floats immediately on getting through the gate, and so power is not lost.

Undershot wheels should be used where the streams are rapid, contain large bodies of water, and are not subjected to much rise or fall, for in the event of a flood the wheel would become "drowned," and its power crippled.

The great advantages which an undershot wheel possesses are cheapness in first cost and simplicity of construction, so that it would not be very difficult for anyone to make one for themselves, and they would find that the cost would not be much.

The Overshot Waterwheel receives its power as much from weight as from momentum of the water. In place of a "flume," in which the undershot wheel receives its power, the water is delivered to the overshot wheel from above, so that it falls just beyond the top centre into buckets attached to the periphery of the wheel. Fig. 3 gives an illustration of an overshot wheel, and the way in which water is delivered to it. A wooden trough, made of planks, delivers the water; at the end of the trough a thin piece of iron is fixed on the bottom of the trough and projects out, forming a lip; this lip reaches the wheel a little in advance of the vertical diameter of the wheel; the water as it rushes out leaps off the lip and so is carried a short distance forward, and, therefore, falls on the buckets a little beyond the top of the wheel. A

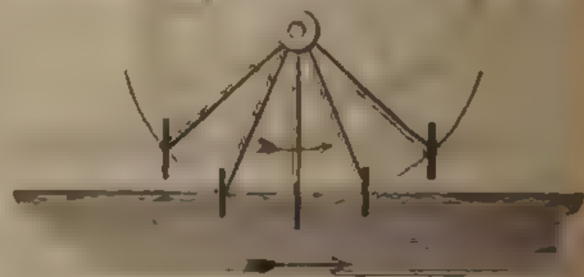

Fig. 1.

sluice is fixed at the entrance to the trough, and so the water can only enter in a thin stream. This type of wheel can only be used where there is a good fall of water; quantity of water does not much signify, provided there is a fall. It may be reckoned that an overshot wheel requires a fall about 1¼ times the diameter of the wheel.

The Breast Waterwheel is a combination of the undershot and overshot, and is probably more used than either of the others. As with the undershot, a flume of masonry is built for the race; the walls of the flume are so made that the wheel will just fit in, there being no space ... left between the floats and the walls. This is in order to prevent any water from escaping past the floats. Fig. ... shows how the water is delivered to a breast wheel. A curved piece of iron fixed at the entrance to the flume is called the "guide bucket." A gate, capped with an ... beak, called the "sole of the weir" (not shown in Fig. ...) is often used, the water flowing over the "sole" and striking the floats just below the axis of the wheel as it does in Fig. 4.

Fig. 2.

For high speed, use wide floats and small diameter.
For low speed, use narrow floats and large diameter.

The following is the efficiency of the three types of waterwheels:

Overshot utilises	50 to 70	per cent.
Breast utilises	45 to 50	,,
Undershot utilises	27 to 30	,,

The Pelton Waterwheel.—This motor is a great improvement on the ordinary wooden waterwheel, being built of iron and encased by an iron shell, the water being fed into it by an iron delivery pipe; a regulating wheel valve regulates the amount of water admitted, and so the power of the motor can be varied. These motors have lately been provided with a throttle valve and centrifugal governor, so that the speed can be regulated when the load varies.

(II.) *Turbines.*—This class of water motor may be divided into two types—namely, (*a*) outward flow, (*b*) inward flow.

When the power is used for driving dynamos, and running

electric lights direct from the dynamo, then a turbine should be used, because a waterwheel cannot be depended on to run steadily; an ordinary waterwheel with its irregular running is quite good enough for driving a dynamo, when it is only used for charging accumulators, because it is not absolutely necessary to have a constant speed, and a variation of speed will not matter, provided it is within reasonable limits. Of course a great deal depends on the nature of the water power. In districts where it remains fairly constant in power the lights can be run successfully by a waterwheel, provided that some regulator is used, such as putting an electrical regulating device across the main terminals of the dynamo, so as to throw resistance in and out of the shunt coils.

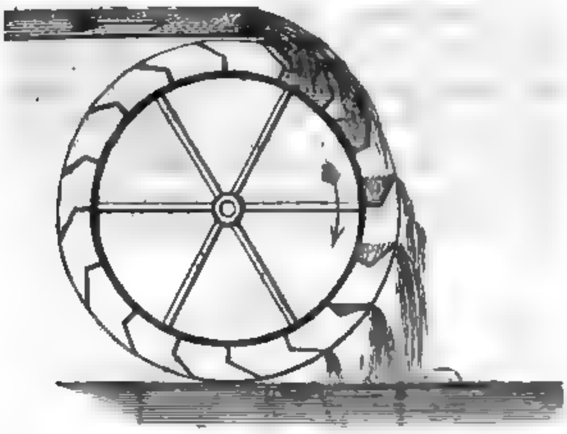

Fig. 3.

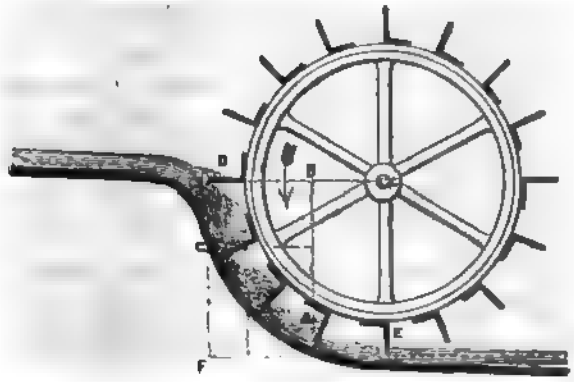

Fig. 4.

The principle underlying the action on which turbines work, may be termed to be the effect of a reactionary force. For an example of what is meant by this definition, it will be remembered that the first instance in which steam was employed to promote motion, and consequently yield power, is generally ascribed to Hero of Alexandria, who partly filled a metal sphere with water and attached two curved spouts diametrically opposite to each other; upon boiling the contained water steam issued from the spouts, one jet rushing upwards and the other jet rushing downwards, and the sphere, being pivoted, revolved. This illustrates to some degree the signification of reactionary forces. The following explanation given by Bodmer will aid in understanding this principle of reaction as regards water: "The construction of turbines is based upon the fact that when a mass moving in a given direction with a given velocity is impelled to change this direction, force is required to effect this change. The intensity of the force necessary is obviously dependent on the extent to which the mass is deflected from its original course. In a turbine a jet of water is deflected by being brought into contact with a curved vane, which, preventing further progress in the initial direction, compels the water to follow its surface. Owing to the resistance offered by the water to this compulsion, a reactionary force is exerted on the vane which is employed driving the turbine wheel." Fig. 5 illustrates how the above reactionary force is practically applied, where, instead of the water being turned abruptly from a vertical to a horizontal course, the arms make a curve, as seen in the section; in addition to this the arms are curved horizontally, as seen in the plan.

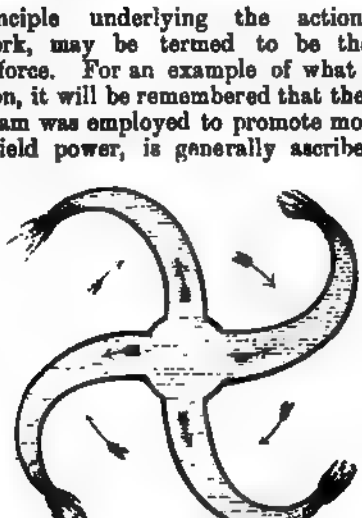

Fig. 5.

In outward-flow turbines, the water enters at the centre, and leaves at the circumference, the guides being placed inside the wheel. In inward-flow turbines, the converse holds—that is, the water enters at the circumference and leaves at the centre, the guide blades being fixed round the periphery of the wheel. A good turbine should give out 70 per cent. of the available power, so that they are far more efficient than waterwheels.

How to Calculate Water Power.—After the explanations given as to the meaning of horse-power and how it is calculated in a steam engine, it will not be very difficult to apply the same to water power. Quantity of water is usually stated in gallons, but in calculating power the water must be measured in pounds weight, for the term gallons is no use, and has to be changed into weight. When the water yields power, by virtue of its dead weight, as when it falls freely from a height, then the theoretical power it gives out just upon reaching the ground is measured simply by the weight in pounds per minute that flows, and the distance in feet that it falls (neglecting air resistance). Now one cubic foot of water weighs 62·5lb., therefore one cubic foot per minute falling 1ft. will yield 62·5 foot-pounds per minute, and since 33,000 foot-pounds make 1 h.p., therefore 528 cubic feet of water per minute, or 8·8 cubic feet per second, falling freely 1ft., will produce 1 h.p. In order to obtain the number of cubic feet of water, the velocity of the water must be measured as near to the fall as possible. The average depth and width of the stream multiplied together give the average sectional area of the water that is flowing, therefore multiplying this by the velocity in feet per minute will give cubical amount of water that flows per minute.

Example.—Suppose a stream, having an average depth of 5in. and an average width of 9ft., has a free fall of 13ft.; find its horse-power, the velocity just above the fall being, say, five miles per hour.

The sectional area $= 9 \times (5 \div 12) = 3{\cdot}75$ square feet;

Five miles per hour = 440ft. per minute;

$\therefore$ quantity of water per minute $= 3{\cdot}75 \times 440 = 1{,}650$ cub. ft.

$\therefore$ weight of water per minute $= 1{,}650 \times 62{\cdot}5 = 103{,}125$lb.

Hence, power developed $= \dfrac{103{,}125 \times 13}{33{,}000} = 40{\cdot}6$ h.p.

In the above case we have measured the power given out by the water by a certain weight of water in pounds falling a certain distance in feet in a certain time—one minute—that is to say, in foot-pounds per minute.

Now turn attention towards measuring the power of water developed, not by weight, but by momentum. Momentum signifies the stored-up or kinetic energy possessed by a body by reason of its velocity.

When a mass of water is travelling along at a certain velocity, the amount of power it would yield upon being suddenly stopped, would be equal to the amount of power that was given to it in order to give it that velocity. The simplest way to find out what amount of power a moving mass has is to calculate out what vertical distance the mass would have to fall, acted upon by gravity, in order to acquire that velocity, and then to proceed as usual. A body falling freely is constantly accelerating its velocity or rate of motion. Thus it starts from rest, having a velocity of 0,

and goes on increasing in velocity until at the end of one second of time its velocity is 32·2ft. per second, and its *average* velocity throughout the space of that second is naturally $(0 + 32·2) \div 2 = 16·1$ft. per second, and the distance fallen is 16·1ft. In the next interval of time, its *initial* velocity is already 32·2ft. per second, while its final velocity is 64·4ft. per second at the end of the second second; hence its *average* velocity during the two seconds is $(0+64·4) \div 2 = 32·2$ft., and so on until at the end of 12 seconds its *final* velocity would be 386·4ft. per second, its average velocity $(0+386·4) \div 2 = 193·2$ft. per second, and therefore the total space covered by the falling body would be $193·2 \times 12 = 2,318·4$ft., so the law is—

$$\text{Space} = \{0 + (32·2 \times \text{time})\} \div 2 \times \text{time, or } s = 16·1\, t^2,$$

where s = space in feet, and t = time in seconds.

In words this means that the distance in feet a body will fall is obtained by multiplying the square of the time in seconds by 16·1.

Example.—A stone falls down a precipice; at the end of four seconds it is seen to strike the surface of a pool of water at the bottom; how deep is the precipice? Applying our rule, we have

$$s = 16·1\, t^2 = 16·1 \times 16 = 257·6\text{ft. deep.}$$

We have now obtained the law connecting space and time for falling bodies, and from this we have to deduce another law—one connecting final velocity and space—so that when a mass is moving at a certain velocity we can find out what distance it would have to fall in order to acquire that velocity. This law would then enable us to measure the energy of the moving mass, for the weight of the mass multiplied by its distance of falling (expressed as a function of its velocity), will give us the foot-pounds of energy it would develop upon being suddenly stopped.

The following is the deduction: Indicating final velocity by v, $v = 32·2\, t$; therefore by dividing the velocity of the mass by 32·2, we obtain the number of seconds it would have to fall to acquire that velocity, and knowing this, the space covered can be easily calculated from the previous law, $s = 16·1\, t^2$, since by substituting the value of t, we get $s = 16·1 \times (v \div 32·2)^2$ = space. This is worked out in the following way:

$$v = 32·2\, t\,;\ \therefore t = v \div 32·2\,;\ \therefore t^2 = (v \div 32·2)^2\,;$$

$$s = 16·1\, t^2\,;\ \therefore s = 16·1 \times (v \div 32·2)^2 = \frac{v^2}{64·4}.$$

Our law, then, is this: Square the velocity of the mass, expressed in feet per second, then divide by 64·4. The answer gives the distance in feet the mass would have to fall, acted on by gravity to acquire that velocity. Hence the stored energy possessed by a moving mass $= \frac{(\text{velocity})^2}{64·4} \times$ weight in pounds.

Example.—Suppose a swift stream of water rushing down an incline at the rate of seven miles per hour, its average depth being 9ft. and its width 25ft.; what horse-power will the stream produce?

Seven miles per hour = 10·26ft. per second;

Cross-section of channel = $25 \times 9 = 225$ square feet;

Mass of water flowing by per second = $225 \times 10·26 = 2,308·5$ cubic feet;

Weight of water flowing by per second = $2,308·5 \times 62·5 = 144,281·25$lb.;

$$\therefore \frac{(\text{velocity})^2}{64·4} \times \text{weight} = \frac{(10·26)^2}{64·4} \times 144,281·25$$

$$= 231,615·6 \text{ foot-pounds per second.}$$

$$\text{Hence horse-power} = \frac{231,615·6}{550} = 421·1.$$

The following tabulation gives a number of values of velocity worked out in their equivalent values of distance:

V = velocity = number of feet per second.

S = space or head in feet.

TABULATION 13.

V	S	V	S
1	·01	20	6·2
2	·06	30	13·9
4	·24	40	24·8
6	·55	50	38·8
8	1·00	60	55·9
10	1·55	80	100·0

Feet per second = $1\frac{1}{2}$ times the number of miles per hour ($2\frac{1}{4}$ per cent. too high).

Miles per hour = two-thirds the number of feet per second ($2\frac{1}{4}$ per cent. too low).

The preceding values are plotted out in a curve, as shown in Fig. 6, where velocities are plotted along the vertical axis, and the spaces along the horizontal axis.

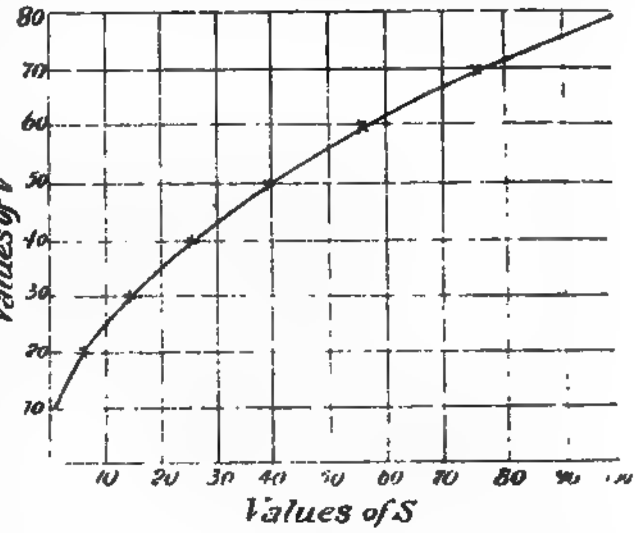

FIG. 6.

Since one cubic foot of water weighs 62·5lb., therefore the energy of one cubic foot of water moving with V velocity is

$$\frac{V^2}{64·4} \times \frac{62·5}{1} \text{ foot-pounds.}$$

Multiplying this by the number of cubic feet of water that flow by per second, will give the foot-pounds developed per second by a volume of flowing water: 550 foot-pounds per second are equivalent to 1 h.p., and since 62·5 is sufficiently near to 64·4 for approximate results, these two factors can be omitted. Now, volume in cubic feet per second is the product of cross sectional area in square feet and velocity in feet per second: hence this formula may be written

$$\frac{V^2 \times \text{area} \times V}{500} = \frac{V^3 A}{500} = \text{H.P.}$$

Where V = velocity in feet per second,

and A = cross-sectional area of stream in square feet.

We can thus obtain the horse-power of a flowing stream of water by the use of the following rule for approximate results only: Cube the velocity of the stream, expressed in feet per second, multiply this by the average cross-sectional area, expressed in square feet, and then divide by 550.

The above rules for calculating water power only give theoretical results, since there are several things which must be taken into consideration in obtaining the actual power—for example, the depth must be very carefully noted in several places, and only the mean or average taken. Then again it must be remembered that the water at the bottom and at the bank sides flows slower than that in the central parts of the stream. This is due to the friction existing between the earth and the water near it, for everyone knows that in rowing against the stream a boat should hug the bank.

(To be continued.)

FINE ART ELECTRICAL FITTINGS.

The development of electricity as a means of light has given an immense impetus to the industry of the fitting trade, and undoubtedly a certain degree of success has been achieved in this country in producing designs which compare favourably with the chandeliers and other appliances in use for lighting by gas. This concession, however, is but faint praise when it is considered how inartistic, and in the majority of cases how hideously ugly, are the gas

Natural-Tinted Floral Electric Fittings.

fittings to which we have so long accustomed ourselves to tolerate. The great difficulty experienced by the great number of makers of electroliers seems to be to shake off the old conceptions, and to get rid of the antiquated traditions connected with gas chandelier designing. So tenaciously do these workers cling to the old forms that it would appear almost hopeless to expect them to leave the gas-chandelier prejudices behind and strike out in an entirely new direction. The art of lighting by electricity lends itself to so many possibilities due to the nature of the new illuminating power that we have long expected to see a larger amount of really artistic development in the gigantic industry which has been brought about by the invention of the incandescent lamp. We have been shown some very artistic fittings recently introduced by Messrs. John Davis and Son, of All Saints' Works, Derby, which can be seen at their London showrooms, 118, Newgate-street. These possess the merit of perfect freedom from the objectionable gas-chandelier type, and should meet with great favour for house lighting of the better type. The designs are very numerous, reaching upwards of 500, so that every variety of condition may find its requisite design of fitting. The electroliers, in varied floral designs, for two up to fifty lamps, are suitable either for the smallest room or the largest saloons or halls of palaces. Brackets, wreaths, cornice lights, theatre-box illuminations are all well represented. The designs are not only elegant, but the workmanship is of a high order, the finish being in gilt, silver, bronze, or a combination of all.

A special feature of the firm's work is the production of floral fittings in natural tints, flowers and foliage being enamelled by a special process in spring, summer, or autumn colouring. The effect is very striking and peculiarly harmonious under the brilliant light of the incandescent lamp. This enamelled work has, moreover, the important advantage of resisting the wear and tear of time, as a wet cloth or sponge suffices to renew the freshness of the work to its original condition.

We must refer our readers to Messrs. Davis and Son for the privilege of inspecting their specimens and photographs at their City showrooms. We illustrate a few representative pieces, which will convey some impression of the new departure in electric fittings.

ABSTRACT OF REPORT ON TRIALS OF PARSONS'S CONDENSING STEAM TURBINE, USING SUPERHEATED STEAM.

BY PROF. EWING, F.R.S., M.I.C.E., CAMBRIDGE UNIVERSITY.

(Concluded from page 483.)

In the second set of trials the object was to test the effect of additional superheating. A special furnace, built into the uptake of the boiler flue, was made to give additional heat to the superheater, bringing the temperature of the steam to 165deg. F. In this set of trials the continuous current armature was again used, and the measurements were made in the same way as in the first set. Three different grades of output were tested. The results are given in Table II.

In the third set of trials the alternate current armature was used, giving 2,000 volts at a speed of 4,800 revolutions per minute, which made the frequency of alternations 80 periods per second. Here the current was directly measured by the Everett and Siemens instruments, and the volts were determined by (1) a Cardew voltmeter furnished with a resistance specially wound to enable it to read 2,000 volts, and independently (2) by another Cardew voltmeter with a step-down transformer having a ratio of 1 to 20. The output was taken to be the product of the effective volts and the effective amperes. In these alternate-current trials the electrical energy was absorbed by a water resistance formed by sticking two rods, to serve as terminals, some 10 yards apart in a pond, the amount of resistance between them being adjusted by pulling the rods out or in to expose more or less of their surface to contact with the water. In this third set of trials the steam was moderately superheated as in the first set, by the hot gases of the boiler flue only, its temperature again approaching 400deg. F. The results are given in Table III. The close agreement of them with the corresponding continuous-current trials, Table I., is important, as supplying evidence that in alternate-current trials conducted in this manner the effects of lag in the external circuit are immaterial, in other words that the electrical work is properly measured by multiplying the effective volts by the effective amperes. The difference between the alternating and continuous-current measurements is less than 1 per cent. of the output at full load.

In each of the trials the turbine was kept running for a [illegible] time beforehand to establish a nearly uniform regime. [illegible] was kept up long enough to prevent any material error from arising in the [illegible] readings of the water level in the boiler gauge glasses. In each trial the amount of the feed water was measured during two successive equal periods of time, to test the agreement of these with each other. The air pump and [illegible] pump were driven by donkey engines, the steam for which was supplied from a separate boiler, and is not included in the figures given below. What the tables give is the gross amount of feed water actually delivered to the main boiler, from which the whole supply of steam for the turbine was drawn.

The temperature of the steam was read by a thermometer placed in a mercury pocket in the steam pipe, close to the turbine. A pressure gauge placed there showed that the pressure was, at full load, between 2lb. and 3lb. per square inch less than the pressure at the boiler. The amount of superheating in the trials of Table I. was comparatively small under light loads, because the boiler [illegible] was not then being forced; from half load to full load it was nearly uniform.

TABLE II.—Trials with Continuous Current Armature, with Extra Superheating.

Pressure by gauge on boiler, lbs. per sq. in.	Temperature of steam, deg. F.	Load in electrical units per hour.	Feed water per hour in lbs. Total.	Per unit.
102	463	28·3	1,000	[illegible]
102	468	49·5	1,480	[illegible]
101	465	78·4	2,170	[illegible]

Vacuum by gauge on condenser, 28¼in. Barometer, 29·5. Temperature of injection water, 72deg. F.

TABLE III.—Trials with Alternate-Current Armature and Water Resistance. Superheating by the Gases from the Boiler Furnace.

Pressure by gauge on boiler, lb. per sq. in.	Temperature of steam, deg. F.	Load in electrical units per hour.	Feed water per hour in lbs. Total.	Per unit.
99	367	31·6	1,180	[illegible]
97	394	49·9	1,550	[illegible]
103	399	105·2	2,970	[illegible]

Vacuum in full power trial: By mercury column at [illegible], 27¼in.; by gauge on condenser, 28¼. Barometer, 29·6. Temperature of injection water, 72deg. F.

The results are also exhibited in the curves, Figs. 3 and 4. The rate of electrical output is shown in relation to the whole consumption of feed water per hour, in Fig. 3, and in relation to the consumption of feed water per electrical unit, in Fig. 4. The line A A in each diagram refers to the first set of the present trials, those of Table I., which were made with continuous current and moderate superheating. The points of observation are marked thus [illegible]. The points marked [illegible], which lie very close to [illegible] and a trifle below it, are for the tests made with alternating currents, Table III. The line B B in each diagram refers to the trials with extra superheating, Table II. The points of observation are marked thus [illegible].

To facilitate comparison, the amount of feed water used per electrical unit at various rates of output, as measured from the curves of Fig. 8, is given numerically in Table IV.

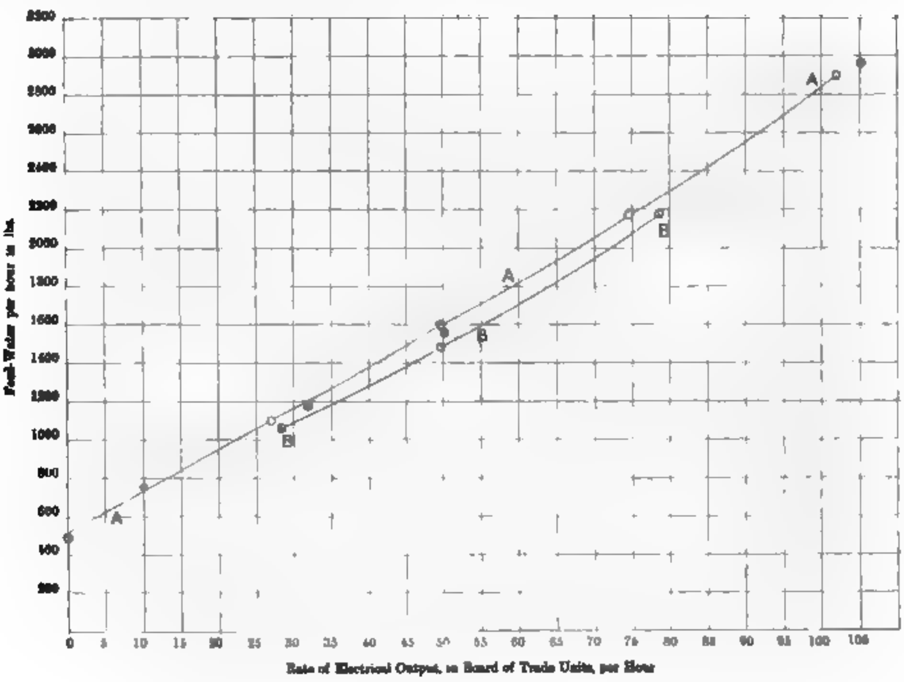
TABLE IV.—Consumption of Feed water at Various Rates of Output, with Superheating.

Rate of output in electrical units per hour.	Feed water per electrical unit. With superheating to about 400deg. F.	With extra superheating to [illegible]
20	48	
30	39	36½
40	34½	32
50	32	29¾
60	30¼	28
70	29¼	28
80	29	27½
90	28¾	[illegible]
100	28½	[illegible]

The trials show that a very considerable advantage is realised by moderate superheating. To superheat the steam from, say, 338deg. F., the temperature of saturation for a boiler pressure of 100lb., to 400deg. F. requires the addition of barely 30 units of heat, which is less than 3 per cent. of the heat taken up in the boiler. With steam superheated to this extent the consumption at full load is less by one-fourth than the consumption in the [illegible] trials. How much of this increase in economy is due to superheating alone cannot well be distinguished without further tests, as the comparison is complicated by the other improvements referred to at the beginning of this report. It is clear, however, that superheating is responsible for a great part of the [illegible]. Apart from the increased volume of the working substance, the advantage of superheating is to be ascribed in part to the prevention or reduction of the condensation which would otherwise take place in consequence of the [illegible] of admission, and in part to its influence in keeping the steam dry during its expansion, and thereby reducing the internal [illegible]. At full load, when the steam enters in a nearly continuous [illegible], the latter effect is no doubt the more important.

The further advantage realised by superheating to 465deg. F. is comparatively small, especially at high loads. From [illegible] given by the temperature of the turbine case it was clear that this amount of superheating not only kept the steam dry throughout its whole course through the turbine, but left it still considerably

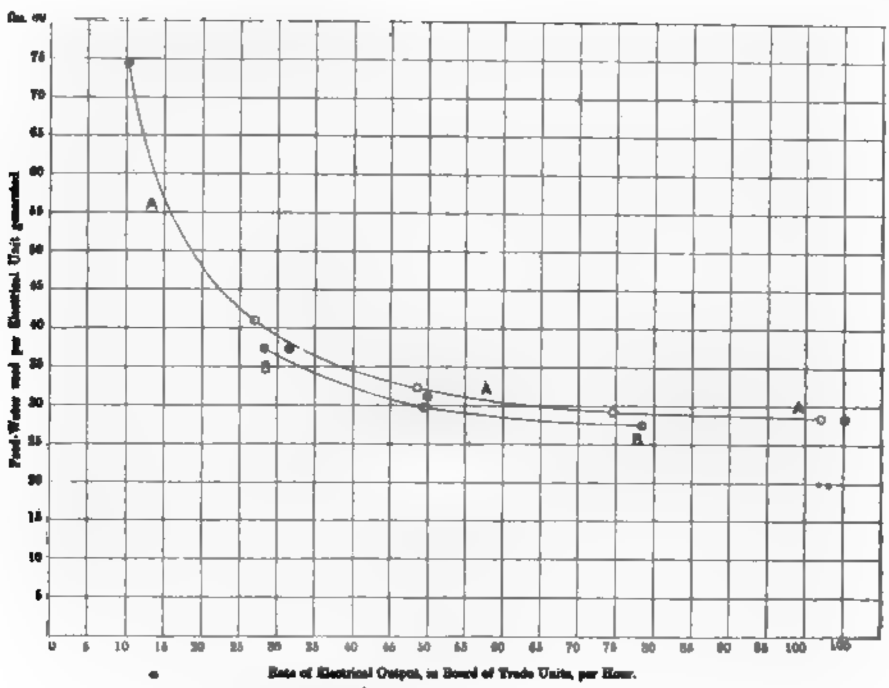
superheated at the end. The part of the case next the exhaust, which had been quite cool in the trials of Table I., was decidedly hot in those of Table II. This observation agrees with the result of calculation, which shows that an initial temperature of about 443deg. F. would be high enough to prevent the steam from becoming wet as it expands.* It may be concluded from this consideration, as well as from the results of the trials, that very little increase of efficiency is to be brought about by carrying the superheating further than this. It seems, therefore, undesirable to push the superheating to a higher point than can readily be reached by the use of a superheater in the boiler flue. With a superheater of moderate size the hot gases of the uptake will furnish as much superheating as need be aimed at, and as much as is sufficient to secure highly economical working.



Trials of Parsons' Steam Turbine and Dynamo, August 1892.
A A.—Steam superheated to about 400° Fah., Continuous current trials ; Alternating current trials
B B.—Steam superheated to 465° Fah., Continuous current trials

FIG. 3.

The general result of the trials is to demonstrate that the condensing steam turbine is an exceptionally economical heat engine. The application to it of moderately superheated steam has put the performance of the turbine on a level with that of the best steam engines of the ordinary type. A consumption of 27lb or 28lb. of steam per electrical unit, at full load, and 30lb. or 32lb. at half load, is a result that does not need to have its significance emphasised. The efficiency under comparatively small fractions of the full load is probably greater than in any steam engine, and is a feature of special interest in relation to the use of the turbine in electric lighting from central stations.



Trials of Parsons' Steam Turbine and Dynamo, August 1892
A A.—Steam superheated to about 400° Fah. Continuous current trials , Alternating current trials
B B.—Steam superheated to 465° Fah. Continuous current trials

FIG. 4.

* Taking the initial pressure as 115lb. per square inch absolute, the temperature of saturation is 338deg. F. Superheating to 443deg. F. makes the total energy of each pound of steam at admission 1,235 thermal units. Each pound does work equal (at full load) to about $\frac{1}{11}$th of an electrical unit; and the thermal equivalent of this is 122 thermal units. Hence, if we neglect the small loss of heat which occurs through radiation and air convection from the turbine case, steam at 100lb. pressure initially superheated to 443deg. F. will retain at exhaust a total heat of 1,113 thermal units. This makes it just saturated, for 1,113 thermal units is the total heat of 1lb. of saturated steam at the final pressure of 1lb. per square inch.

The consumption of 28lb. per unit corresponds to 20·9lb. per electrical horse power hour. To facilitate comparison with other engine trials, it may be useful to estimate from these results what may by analogy, be called the "indicated" horse power of the turbine—that is to say, the mechanical work done by the steam on the turbine blades. The curves of Fig. 7 are nearly straight lines, and by prolonging them backwards to meet the base line produced, it appears that the idle work—that is to say, the work done without useful output—was equivalent to 27 kilowatts, or 36 h.p. The effective work at full load, the equivalent of 100 electrical units per hour, was 134 e.h.p. Hence, if the idle work had the same value at full load as when the machine was running light, the total work done by the steam at full load would be 170 h.p., and the effective work, 134 h.p., would be 79 per cent. of the total. But the idle work certainly increased when the machine was loaded, and it will be nearer the truth to assume that the effective work was not more than 75 per cent. of the total work. This would make the total work about 179 h.p. On this basis, a consumption of steam at the rate of 28lb. per electrical unit is equivalent to 15·7lb. of feed water per "indicated" horse power hour, and 27lb. per unit is equivalent to 15·1lb. per "indicated" horse power hour. Similarly, the consumption of half load is equivalent to about 17lb. per indicated horse power hour.

No allowance, as has been said, was made in these trials for leakage of steam and water from the boiler. It is well known that some leakage occurs under the most favourable conditions, and that if the quantity of steam used were measured after passing through the engine—as is often done in tests where a surface condenser is used—the results would be more favourable than those obtained by direct measurement of the feed. In the present instance it appeared from separate observations that the losses by leakage amounted to about 90lb. per hour, or, say, 3 per cent. of the whole consumption in the full power trials. If this allowance were made, the quantities of steam per horse power hour and per unit would be reduced below the values stated above by about 3 per cent. in the full power trials, and by about 6 per cent. in the half power trials.

By applying the indicator at various parts of the turbine case, the range through which the pressure varies as each gust of steam passes, and the fall of pressure from one set of turbine rings to the next throughout the series, may be examined. This was done during the trials, with the result of showing that the apertures of the several turbines were not adjusted in the best possible relation to one another; in particular it was found that the turbine rings on the large disc at the condensing end gave too free a passage, and were doing less than their proper share of work. The re-adjustment of areas indicated by this test as desirable will, no doubt, secure even better results.

Apart from the other possible applications of a peculiarly light and efficient high-speed motor, the turbine dynamo in its present state is, in my opinion, eminently well fitted for central station use, not only on account of its economy of steam under both heavy and light loads, but also on account of its exceptional lightness and compactness, its small first cost, its independence of foundations, its freedom from vibration, its steady governing, its simplicity, the ease with which it is handled, and the moderate outlay which it may be expected to require under the heads of maintenance, oil, and attendance. So far as I have been able to judge, the performance of the machine is as excellent as its details are ingenious.

LEGAL INTELLIGENCE.

HOPKINSON v. THE ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY.

Mr. Hopkinson, Q.C., on Thursday in last week, with the consent of both parties to this patent action, the further hearing of which had been adjourned till Monday last, asked that the case might stand out of the list generally, with liberty to apply to restore it.

Mr. Justice Romer made the order asked for.

COMPANIES' MEETINGS.

WEST INDIA AND PANAMA TELEGRAPH COMPANY, LIMITED.

The thirty-first ordinary general meeting of this Company was held on Tuesday at Winchester House.

Mr. C. W. Earle presided, and in moving the adoption of the report stated that, although there had been a decrease of £4,762 in the receipts and an increase of £3,721 in the expenses, it was somewhat better, on the whole, than he anticipated it would be when they were discussing the effect of the reductions in the tariffs which they were compelled to make 12 months ago. He felt pretty confident that the considerable reductions made by them in their tariffs—amounting to very nearly 50 per cent. at most stations—had not produced a single extra message over their lines. When a message cost some pounds to transmit, it was not sent at all unless it was of importance, and, therefore, whether a message cost £3 or £5, the probability was that just as many messages would be sent at the one tariff as the other. The competitors who had invaded this Company's field, so very unnecessarily, as it seemed to him, must regret having expended their money in laying cables in the West Indies. The report submitted by that company at the meeting held last was a very gloomy one, and [illegible] he thought it possible that it would be still worse. They were now broken down in their line to Brazil, and although it [illegible] them very little traffic, yet he thought it would cause a great loss of time, and, if they were forced to repair [illegible] expense. At present that company had no ship on the West Indian stations for repairing purposes. With reference to their own expense on cable repairs, they had had 15 interruptions during the past half year compared with seven in the same period of the previous year, and they had used 190 knots of cable compared with 41 knots in the June half of 1891. This of course would explain the very large increase in the expenditure on cable repairs. As the repairs of the Grenada-Trinidad and Jamaica [illegible] lines amounted to renewals, they had followed the practice previously adopted in repairs of such magnitude, and [illegible] part of the cost to the reserve fund. He concluded by moving the adoption of the report.

Sir James Anderson seconded the motion.

A short discussion followed, and, in answer to questions, the **Chairman** stated that the traffic receipts in the current [illegible] showed an improvement of about £1,700 over those of last year up to the present date; and that repairs, he was glad to say, had been very much less. The Jamaica-Porto Rico line was about one-seventh of their whole cable. Even after charging the [illegible] renewals in question to the reserve fund it stood at [illegible] what it ought to be in the twenty-third year of [illegible] existence. About £7,000 of the cost of the new cable and repairs had been charged to revenue account, and [illegible] in the light, was quite a legitimate charge to the reserve fund. The cable between Jamaica and Colon, on which they obtained [illegible] any traffic, was not duplicated, but all the other cables were.

The motion was adopted.

BUSINESS NOTES.

York.—The date for the York tenders is the 21st inst.

Hove Town Hall.—The plans and tenders for wiring the Hove Town Hall are to be sent in by 18th inst.

Johnstone (N.B.)—The next meeting of the Johnstone Municipality will consider the lighting of the town.

Cars.—The cars for the Liverpool overhead electric railway are being built by Messrs. Brown, Marshalls, and Co., of B[illegible].

Bell's Asbestos Company, Limited.—The works [illegible] this Company have been removed to Southwark Bridge [illegible] Southwark-street, S.E.

Glasgow.—The Gas and Electric Lighting Committee of the Glasgow Town Council has Mr. William Ure as convener and [illegible] William Stevenson as sub-convener.

Dublin.—The new fish and vegetable market, which has been in progress of erection since March, 1891, is nearly completed. The lighting will be a mixture of electricity and gas.

Arc Light.—The great search light at the World's Fair [illegible] electric arc of 150 ampères, and the illuminating power of its beam is calculated equal to that of 100,000,000 candles.

Western and Brazilian Telegraph Company.—The receipts for the week ended November 11, after deducting 17 per cent. payable to the London Platino Brazilian Company, were [illegible].

Richmond.—The newly elected Mayor of Richmond, A[illegible] Burt, referred on taking office to the electric lighting as one of the important matters that were requiring earnest attention this year.

Totton.—Tatchbury Manor, the residence of Mr. [illegible] Wilson, C.C., is now lighted by electricity, which is also [illegible] into requisition in connection with the dairy and other parts of the premises.

Derby.—The Electric Lighting Committee of the Derby Town Council consists of Aldermen Bemrose, Hextall, L[illegible] and Woodiwiss, Councillors Bottomley, Bowring, Butterworth, Harrison, E. Haslam, and Stone.

Bristol.—Tenders for underground mains, arc lamps and posts for Bristol central station will be received until Dec. 1 by Mr. D. Travers Burges, town clerk. Forms of tender and specifications are obtainable on payment of £2.

Switch Invention.—The name of one of the inventors of the new switch we described last week which was given as [illegible] should be Husk. Mr. W. A. Husk is superintendent of public lighting to the St. Pancras Vestry.

Northampton.—The Highway and Lighting Committee of the Northampton Town Council report that, after inspecting the electric light in the Market-square, they have asked the engineer of the electric light company to send an estimate for lighting the square.

Shoreditch.—Mr. E. Manville, 39, Victoria-street, Westminster, on behalf of his firm, Messrs. Waller and Manville, has been appointed consulting engineer to the Vestry of St. Leonard, Shoreditch, to advise them on their proposed electric lighting undertaking.

City and South London Railway Company.—The receipts for the week ending November 13 were £860, against £[illegible] for the corresponding period of last year, or an increase of £[illegible]. The total receipts for 1892 show an increase of £1,533 over those for the corresponding period of 1891.

Paisley.—Tenders for the transference of their electric lighting powers are invited by the Paisley Town Council. Information by appointment from Mr. W. A. Bryson, M.I.E.E., 11, Bothwell street, Glasgow. Tenders received up to 28th inst. by Messrs. Young and Martin, town clerks, Paisley.

Liverpool.—The main construction of the Liverpool Overhead Railway is now practically finished, and the details which have yet to be attended to will take but a very short time. It is understood that the railway will be opened for traffic within the next month. As stated in our last issue, a successful run has been made.

Sugar Refinery.—J. and R. Houston, Cartburn Foundry, Greenock, have received a contract to construct buildings, plant, and machinery for a sugar refinery in the East, to be capable of producing 3,000 tons of refined sugar in a month. The works are to be fitted with all the latest improvements, including the electric light.

Fleetwood.—The Fleetwood Commissioners, having definitely decided upon a scheme of electric lighting, have appointed a committee to negotiate for the purchase of a site near Copse road, for the erection of the necessary works. The Commissioners have had before them tenders and reports from 16 electrical engineers and companies.

Weston-super-Mare.—At the last monthly meeting of the Town Commissioners the question of a company taking over the provisional order was discussed. Enquiries had been made, and the Commissioners agreed that they would consider a proposition coming from a substantial company provided the conditions offered were satisfactory.

Cambridge.—At the annual meeting of the Cambridge Town Council last week, it was resolved, on the motion of Councillor Ginn, seconded by Councillor Vinter, that the seal of the Council should be affixed to the deed of transfer of the powers of the Corporation under the Cambridge Electric Lighting Order to the Cambridge Electric Supply Company, Limited.

Accrington.—In consequence of the Accrington Gas Company having raised the price of gas by 3d. per 1,000 cubic feet, the extensive firm of Messrs. Howard and Bullough are fixing a small installation of electric light at their works with a view of dispensing with the use of gas. The moulding shop and technical school have been lighted by electricity for some time.

Scarborough.—There will be some good contracts conjoined with a lively outing for electrical men during the coming spring, if the signs of the times are correct. The Mayor of Scarborough, on his election, dwelt specially on the paramount importance to the town of the general adoption of the electric light, which it was hoped would be carried out during his term of office.

Wigan.—The following gentlemen constitute the Gas and Electric Lighting Committee of the Wigan Town Council: Mr. C. B. Holmes (chairman), John Gee (vice-chairman), the Mayor, Aldermen Ackerley, Hilton, Heywood, Richards, and Smith, and Councillors Benson, Booth, Baldsworth, Joseph Wilson, W. Rigby, Gaskell, Henderson, John Johnson, Worswick, and J. Woods.

Barnard Castle.—A committee has met the representative of the Brush Electrical Engineering Company, Mr. J. J. Hall, to receive an approximate estimate for lighting the town of Barnard Castle with electric light. Mr. Hall has made an inspection of the river with a view of utilising the water power, and the matter was discussed in detail. The Lighting Committee are expecting further particulars and plans.

Farnworth, near Bolton.—The Farnworth Local Board have appointed a committee to consider whether or not the electric light should be adopted for the town. The town is at present supplied with gas by a private company, and there have been numerous complaints from millowners and private consumers as to the bad quality of the gas. In one case the illuminating power was so bad that the mill had to be closed.

Morecambe Tramways.—The directors of the Morecambe Tramways Company report that the provisional order authorising the company to construct an additional line was confirmed by Parliament in June last. The Board of Trade declined to consent to the use of electricity as the motive power until such time as the road west of The Midland Hotel be widened. The directors propose to proceed with the construction of the line from the new pier to East View in readiness for next season's traffic.

Swan United Electric Light Company, Limited.—For the year ended September 30, 1892, the Directors have resolved, subject to audit, to recommend the shareholders to declare a dividend as follows: 4s. 2½d. per share on the 78,949 ordinary shares (£3 10s. paid), and 4s. 11½d. per share on the 19,750 £5 (fully paid) shares, free of income tax. This, together with the interim dividend paid on May 31 last, will make a total distribution of 10 per cent. for the year on the ordinary £3 10s. paid shares of the Company. The dividend will be paid upon the register as it stands this day, and the warrants will be issued on December 13.

Burton.—The Gas and Electric Committee of the Burton Town Council, in their report presented at the last meeting, announced that the gas manager, Mr. Ramsden, had produced plans of the districts to be lighted by electricity. The cost of the project was given as £25,000, and the committee recommended that application for a loan to that amount be made. In answer to a question, Alderman Lane, on the authority of the gas works manager, said that the engine at the refuse destructor was not of sufficient power to be used for the electric light. The committee were empowered to apply to the Government Board for permission to borrow the required amount.

Train Lighting.—An order for accumulators for lighting a further seven trains on the Brighton and South Coast Railway has been received by the Electrical Power Storage Company. This railway company has already 23 trains lighted, and, with the seven now in hand, will have 30, which are expected to be in use after the commencement of the year. In addition to this, their telegraph superintendent, Mr. Houghton, informs us that there is every possibility of very large extension in the near future.

Islington and Hackney.—The Islington Vestry and the Hackney District Board of Works have each given notice of an intention to make application to the Board of Trade, under the Electric Lighting Acts of 1882 and 1888, for a provisional order enabling them to produce and supply electricity and electric light for public and private purposes within their districts. Among the streets in which it is proposed to lay the electric mains, should the application be granted and the order confirmed by Parliament, are High street and Upper street, Islington; Holloway road and Seven Sisters road; High street, Kingsland; High street, Stoke Newington; Kingsland road, Mare street, Stoke Newington road, and Dalston lane.

International Electric Syndicate.—Mr. Justice Vaughan Williams, sitting in Bankruptcy in London on the 9th inst., granted a winding-up order in the case of the International Electric Syndicate, a company whose registered office is in Manchester. The petition was presented on behalf of Mr. C. H. Hodgson, a holder of 500 shares, and was granted under that section of the Companies Act which states that if a company has carried on no business within one year of the date of its incorporation it may be wound up. Moreover, it was stated that the registered offices of the company in Manchester had never been opened, and no business had been carried on.

Coatbridge.—Certain statutory notices are now running with reference to the Coatbridge installation which do not expire till the 28th inst., and during the currency of these notices nothing can be done in the way of breaking ground. The manufacture of the necessary mains is being pushed forward with all speed, and the contractors only await delivery of these and the expiry of the notices to commence work. The machinery is being built, and when completed and erected will embrace all the most modern improvements in electric lighting. The contractors intend to make the Coatbridge installation a model in all respects, and it is anticipated that the company will be able to supply electric light as cheap as the present gas.

Claybury Asylum.—The Asylums Committee of the London County Council are prepared to receive tenders for the installation of electric light at the London County Lunatic Asylum in course of erection or completion at Claybury, Woodford, Essex. Printed forms, bond, and lithographed copies of the drawings, can be obtained on application to the clerk of the committee, at the offices of the committee, 21, Whitehall place, S.W., on payment of £2, which will be returned on a bona fide tender being delivered within the appointed time, or on return of the forms and drawings before that time. Tenders must be delivered at the offices of the committee not later than noon on December 6, 1892. The contractor will have to enter into a bond in the penal sum of £300, with two approved sureties, each in £150, as security for the due performance of the contract.

Weston-super-Mare.—The Town Commissioners of Weston-super-Mare were much agitated at their last meeting on the question of electric light. It seems that a firm of accountants, Messrs. Curtis, Jenkins, and Co., of Bath, have written to know upon what terms the Commissioners will hand over their electric lighting powers. A long discussion ensued on the resolution to entertain this proposal. Desire was freely expressed that the Board should keep the matter in their own hands, Mr. Phillips proposing, and Mr. Palmer seconding a motion to this effect. Mr. Pethick, on the other hand, said there was no one on the Board who was competent to see the matter carried out, and if they did not act by June they would be in the hands of outsiders. The report of the Inspection Committee to consider the proposal of the company was finally adopted by a considerable majority.

Madrid.—According to the *Engineer*, it is proposed to build a great dam on the Guadarrama river, near Torrelodones, where a fall of about 200ft. can be obtained. This can be increased to a total of 1,100ft. by building a canal five miles in length. The power obtained will be used to run dynamos, and will be transmitted to Madrid by wire for use in lighting the city and for other purposes. To equalise the power, and provide a supply of water in the dry season, a canal some 15 miles long will be built to connect Lake Pantano with Guadarrama; the lake being thus utilised as a storage reservoir. The plan also includes the use of the water after passing the dam, and water power to supply the city of Madrid and irrigate the country surrounding it. Madrid has now a very insufficient water supply, and the new project, it is expected, will much improve its health and convenience.

Central Station Cells.—The Electric Power Storage Company have recently introduced a new central station accumulator cell, with a number of plates (total) ranging from 42 to 132, with a corresponding maximum discharge rate for one hour of from 350 up to 1,200 amperes. The new central station cells embody the following improvements: Capacity for high rates of discharge, 1,200 amperes for one hour from 61 positive plates as a maximum; lead box with insulated bottom, the plates are fitted in the box, being also provided with lip so that electrical leakage, due to creeping of acid, cannot take place; each set of plates can be separately removed without interference with the remainder or with the circuit; the

area of connections is greatly increased; the arrangement of electrodes is such that the work is uniformly distributed over the whole of the plates, even when working at emergency rates.

Heckmondwike. At the meeting of the Heckmondwike Board last week the Electric Lighting Committee reported that they had held an adjourned meeting, when the terms of a telegram previously received, offering to take 600 lights for the Heckmondwike Shoe Works, was confirmed, the offer being subject to arrangements being made for satisfactory insulation, and that the price did not exceed that quoted by the Board. No resolution was passed upon the letter. Messrs. Wood (chairman of the committee) and Macaulay were appointed to draw up replies to a number of letters from private electric lighting companies who had been written to asking upon what terms they would light the town with electricity at their own cost. The minutes were approved.

Huddersfield. The work of laying the electric mains in Huddersfield, which has been done in a careful and substantial manner, has made satisfactory progress, and is now nearly completed. There are now 2,900 yards of conduit laid for the high-tension mains, 3,550 yards of conduit laid for the low-tension mains, and 64 junction boxes have been built. The conduits for the mains have been laid in the principal streets, which, under the provisional order, form the compulsory area of the borough, and the mains are of sufficient size to meet the future requirements of consumers. The occupiers of a number of shops and offices have already applied to be connected to the electric mains. Some advantageous positions have been secured for the transformer stations, and these are now in course of erection. It is thoroughly expected that by the spring of the coming year the electric supply will be commenced.

Whitehaven. The Whitehaven Town and Harbour Trust had before them at a special meeting last week the question of electric lighting contracts and loans. The committee reported that the surveyor had been instructed to advertise for tenders for the masonry, brickwork, and concrete in engine foundations and boiler seatings in accordance with the specifications. A letter was read from the Local Government Board, enclosing formal sanction for the Trustees to borrow £14,000 for purposes of electric lighting, to be repaid within a period of 20 years, and notifying that the application to borrow an additional £7,000 should be deferred. It was agreed that the seal of the Board should be attached to contracts for electric lighting plant already approved; and on the motion of the chairman it was agreed that the £14,000 should be borrowed, the chairman remarking they would have no difficulty in obtaining it at 3½ per cent.

Electric Light in Flour Mills. Messrs. Christy Bros., electrical engineers, of Colchester, have of late been placing installations of the electric light in numerous flour mills. They are now erecting a very complete plant for 200 lights for Messrs. J. and H. Robinson, Deptford Bridge Mills, Greenwich, consisting of a slow-speed dynamo, driven by 12-h.p. gas engine, and all the latest improvements, including a large number of hand lamps of a new and improved type. They have also made important alterations and extensions in the mills of Messrs. E. Marriage and Sons, Colchester, and Messrs. Lofthouse and Hammond, of Borough Bridge. Among numerous installations in other classes of electric work, they have in hand a 400-light plant at Stockport, a 300-light plant at Maybole, in Scotland, and a large combined arc and incandescent plant in an extensive paper mill at Purfleet. They are making an entirely new application of electricity in a large clothing factory near Bath in the shape of a large number of electric "geese and irons" for ironing the garments.

London County Council. At the meeting of the London County Council on Tuesday, the Highways Committee reported, with reference to the appointment of Mr. A. E. Rosster as inspector, at a salary of £250 a year, that they considered it well for the appointment to be continued on probation until November, 1893, subject to confirmation at this date. Notices were sanctioned for laying mains by the Westminster, the House-to-House, the Kensington and Knightsbridge, and the Notting Hill Electric Companies. The St. James and Pall Mall Electric Light Company had given an emergency notice of intention to substitute armoured cable for the existing bare copper mains across Pall-mall by Waterloo-place. This the committee regarded as a very desirable alteration, and needed to be made in all cases as quickly as possible, so that they were of opinion that the action of the company in treating the matter as one of emergency is justifiable. The committee also recommended that permission be given to the General Post Office to place an additional four-wire cable in the Commercial-road subway.

Burnley. Alderman Collinge, in moving the acceptance of the tenders for electric lighting plant, which we gave last week, said the committee believed the electric lighting station would be finished during the spring, and they were desirous that the other work should be going on at the same time. By doing that they would have the electric light in such a state that anyone desiring to take it up could do so before midsummer, and prevent the great rush that might be made in the winter. The amount of the tenders was £17,700, whereas the original estimate was £19,000 and they had got powers from the Local Government Board to spend £23,000. Alderman Lancaster said the tenders were very elaborate. They had adopted a special system of cable, which ought only to be put in the bottom of the streets. In answer to questions, he said the length of the cables would be about 2,200 yards, the laying entailing a cost of £1,000 additional to the amount mentioned. The building was sufficiently large to accommodate twice the plant, and they [illegible] for further extension when needed.

Coventry.—Considerable discussion is taking place in municipal circles respecting the proposals of Mr. W. F. [illegible], the purchaser of the undertaking of the Coventry and District Tramways Company, to provide a new equipment and install [illegible] traction. The latter is on the overhead wire system, which many object to because of the narrowness of the Coventry streets. On the other hand it is contended that the system can be so modified and adapted as to practically remove all objections. The City Council have up to the present kept the matter at arm's length, some of the influential members of the body being opposed to tramways through the city under any system. The General Works Committee have appointed Alderman Marriott and Councillor Andrews a special deputation to visit Leeds and inspect the working of the system there, and they will do so next week. On Wednesday night, however, an independent party left Coventry for the same purpose—viz., Councillors [illegible] Thomas, Haywood, Webb, Worrall, Fowler, Callcott, [illegible] and Statham. They were accompanied by Mr. Seilon, [illegible] engineer.

Seaforth and Waterloo. A proposal is on foot for the establishment of a central generating station and system [illegible] supplying the electric current throughout the district of Seaforth, Waterloo, Blundellsands, and Crosby, near Liverpool. We understand that it is meeting with a very encouraging [illegible] from the residents who have as yet had the [illegible] before them. A number of gentlemen have already signified their intention of supporting the undertaking. The names include those of the chairman and several members of the two Local Boards and other prominent residents. A circular will shortly be sent round to the householders in the district pointing out the advantages of the light, and enclosing a requisition form stating about how many lights will be required in each house. The system to be adopted will be the alternating current transformer system, which enables a scattered district like the one under consideration to be served economically. The engineer for the scheme is Mr. Wilfrid S. Boult, A.M.I.C.E., 60, Castle-street, Liverpool, and the secretary, *pro tem.*, Mr. Charles Stananought, 41, [illegible] street, Liverpool.

Windermere.—At the monthly meeting of the Windermere Local Board, the chairman stated that an application from Mr. Fowkes for permission to lay an electric cable was considered by the Main Roads Committee of the County Council at their last meeting and they consented on condition that he paid [illegible] per mile per year as way leave, and undertook all risks and the leaving of the roads in proper condition. He supposed the Bowness Board had given their consent, and it only remained for the Windermere Board to do the same, upon similar terms to those granted by the County Council. Mr. Fowkes, who was present, said it was not proposed to obtain a provisional order, but to act as a private company. He would undertake to supply [illegible] terms to be mutually agreed upon. He had already made an agreement with the Bowness Local Board by which the light was to be supplied where required at the rate of 10d. per unit. [illegible] he understood the agreement with the Bowness Local Board was that the electric light should be supplied at the same [illegible] Mr. Fowkes explained that that was in respect of the public lighting only. He could not say whether they could do the same for Windermere, as he had no basis to go upon. Having [illegible] to submit the agreement made with the Bowness Board [illegible] clerk he withdrew, after which a committee, consisting of Messrs. Irving, Garnett, and Pattinson, was appointed to look into the matter, see what arrangements were likely to be suitable, and report to next meeting.

Penarth.—An adjourned meeting of the Penarth Local Board was held on Monday to consider the scheme proposed at the last meeting of lighting the town by electricity. Mr. J. Rose, engineer, of West Bute-street, Cardiff, attended and produced plans showing the principal streets to be lighted. Mr. Rose stated that a powerful company was being formed for this purpose, and should the Board grant the necessary permission, work would be commenced forthwith. He further stated that his company would be prepared to undertake the lighting of the principal thoroughfares at a charge of something under £3 per lamp per annum. In answer to a question, Mr. Rose explained that the price for private houses would not exceed the present gas charge by more than [illegible] per cent. He pointed out that if the Board decided to light the streets this price would be materially reduced. The plans of Mr. Rose were discussed by the Board and favourably received. The chairman asked whether, if the Board decided not to light the principal streets, the proposed company would still proceed with the house-to-house lighting by electricity. Mr. Rose answered in the affirmative, and stated that his principal object was to secure the sole right to carry the necessary wires through the streets. The chairman said the Board would at once consider the question. Mr. Rose then thanked the Board for their courtesy, and, in conclusion, stated the estimated capital required for the carrying out of the project would be about £15,000, and so confident was he of success that his partner and himself were prepared to find one-third of the amount. A suggestion was adopted that the clerk be instructed to apply to all towns which have adopted the system, inquiring how the scheme worked satisfactorily.

Arundel Castle.—The contract for the electric lighting of Arundel Castle, the seat of the Duke of Norfolk, which has been secured by the Brush Electrical Engineering Company, will be one of the largest and most complete private installations in the country, comprising some 1,200 lamps of 16 c.p. for the castle, together with an additional number of lights for the large [illegible] 12 50-c.p. lamps for the drive, and eight 100-c.p. for lighting the

one industry, and should be worked together in the interest of the public at large. Gas for heating can be produced for half the price of gas for lighting. Bradford and St. Pancras have been at work for some time and are making profits. Bristol, Glasgow, York, Manchester, Nottingham, Dundee, Huddersfield, Chester, Burnley, Southport, Blackpool, Portsmouth, Hull, Barnsley, Worcester, Wolverhampton, etc., are already at work; and nearly every other town of importance is either considering or has decided upon taking it up as a municipal industry. The business increases more rapidly when fostered by a corporation than by a company, for the ratepayers, being virtually the proprietors, take an interest in the progress of their own industry when they know that its profits go to the reduction of their own rates. I am sure that in two years 10,000 lamps will be taken up in Yarmouth. The Corporation itself will absorb nearly 1,000. Every hotel must take it for their own prosperity; shops, offices, and private houses follow. Now the average revenue per lamp fixed may be taken at 10s. per annum at 6d. per unit, and 10,000 lamps will produce a revenue of £5,000. The working expenses may be taken at 50 per cent. of the gross receipts, and 10,000 lamps will give a profit of £2,500 per annum to pay interest on loan, to provide sinking fund, and to pay for public lighting, or to reduce the rates. Full allowance is made in working expenses for depreciation and renewal. An electric light plant must always be maintained in perfect working order. Nothing can be allowed to decay or depreciate. I do not recommend the committee to go in for 10,000 lamps at once. I think it will be sufficient to start with smaller plant. The growth of business is easily met by the multiplication of plant. It is proposed to establish the central station at the north end of the South Denes near the Fish Wharf. No place in the whole borough can be found more suitable. Water is abundant, coal is easily delivered. Cheap and expansible buildings can be built there, and units of power can be installed, which can be multiplied as the business increases. I think it would be quite sufficient to start with a capital of £10,000, viz., building £1,500, and plant and mains £8,500. This would give us power sufficient to provide current for 4,500 35-watt lamps. The Corporation have already advertised for tenders, and several tenders have been submitted, which I have carefully examined. They vary so much, and are based on such different assumptions, that I do not recommend the acceptance of either of them, but I suggest to the committee that when the authority of the Council be obtained to expend £10,000, full detailed specifications of a definite plan be prepared upon which comparable and acceptable tenders can be invited from those who have competed. I am a great advocate of public lighting. Brilliant illumination increases the security of our streets. Accidents in large towns are relatively greater during the hours of darkness than during daylight. The amount of light distributed over the roadway by an ordinary street gas burner is very small, and the spaces halfway between the lampposts are not much advanced from darkness. Hence accidents at night are frequent. If one arc lamp replaces four gas lamps, the illumination is improved four times. These 50 arc lamps would replace 200 gas lamps, and give much better effects. Moreover, half of these lamps can be put out at midnight, and hence we find by experience that the cost of maintaining the electric light does not exceed that of gas. Four ordinary gas lamps cost in Yarmouth £13. 4s., and one arc will cost £14 per annum. Public street lighting gives all the ratepayers of the borough an interest in the undertaking. It is, moreover, a great advertisement for the electric light. It tends more than anything else to popularise the movement. Public street lighting favours all classes alike. Moreover, it must be done well, otherwise it would have the opposite effect, as has been the case in more than one instance where very imperfect street lighting was attempted. I do not advocate public street lighting at once. I think it better to start the station on a small basis to acquire experience and secure confidence. But when all is going well, then the illumination of the quays, of the Fish Wharf, of the Market place, and of the Parade and piers by arc lamps will convert Yarmouth into a place of beauty by night. Other seaside resorts will be surpassed, and the town itself will be advertised all over the United Kingdom in a way that no payment would secure."

PROVISIONAL PATENTS, 1892.

NOVEMBER 7.

19902. **An electric energy motor.** Robert Pippette, 31, Endymion road, Brixton Hill, London.

20056. **Improved electrical appliance to be adapted to clocks for giving an alarm.** Victor Durand, 9, Warwick court, Gray's inn, London.

20064. **An improved method of and means for generating currents of electricity for promoting the growth of vegetation.** Robert Henelade Courtenay, 11, Lambourne road, Clapham, London.

20065. **Improvements in the construction of horticultural buildings also with apparatus and means for forcing the growth of vegetation by electricity.** Robert Henelade Courtenay, 11, Lambourne road, Clapham, London.

NOVEMBER 8.

20100. **Improvements in and connected with telephone switches.** William Albert Shaw and Edward Arthur Shaw, 4, Corporation street, Manchester.

NOVEMBER 9.

20214. **Improvements in electrolytical apparatus.** Alfred Julius Boult, 323, High Holborn, London. (O. Knöfler and Fr. Gebauer, Germany.)

NOVEMBER 10.

20254. **Improved arc lamp for photographic purposes.** Henry Bonn and William Hafgood, 43, New Kent road, London.

20272. **An improved electric billiard marker and pool marker.** William Walter Gerard Webb, 9, Coppenhall terrace, Crewe.

20311. **The improved electric engraver.** Charles E. Braun and Frederick Wilde, 37, Oxford street, London.

20316. **Improvements in electric lighting.** Hannah Clegg, Brampton, West Norwood, Surrey.

20333. **Improvements in apparatus for protecting transformers and other electrical apparatus from lightning and from electric currents of excessive strength.** Charles Eugen Lancelot Brown, 40, Lincoln's inn fields, London.

20348. **Improved electric battery cells.** Richard John Black, 70, Deansgate, Manchester.

NOVEMBER 11.

20369. **Improvements in electric arc lamps.** Richard Albert Goodman, Commercial street, Halifax.

20371. **Automatic electrical railway signal.** Alfred George Barrell, 5, King street, Sheffield.

20445. **Improvements in electric motors.** Carl Raab, 28, Chancery lane, London.

NOVEMBER 12.

20478. **The combined automatic charging switch and cut-out.** Rupert Carryer, Queen Anne's mansions, Westminster, London.

20488. **Improvements in apparatus for closing an electric circuit by the passage of a locomotive or train over a line of railway, and recording apparatus connected therewith.** Francis William Webb and Arthur Moore Thompson, Holly Bank, Crewe.

20489. **Improvements in apparatus for sterilising and oxidising liquids by electricity.** Arnold Beaumont W[illegible], 28, Harley street, London.

20505. **Improvements in alternating-current motors.** William Lloyd Wise, 46, Lincoln's inn fields, London. (The Maschinenfabrik Oerlikon, Switzerland.)

NOTES.

Appointment.—The Postmaster-General has conferred the appointment of engineer-in-chief and electrician to the Post Office upon Mr. W. H. Preece, F.R.S.

Society of Arts.—A paper will be read before the Society of Arts on the 30th inst., at 8 p.m., by Mr. Jas. Douglas, on "The Copper Resources of the United States."

Old Students' Association. — The presidential address of this association, entitled "Human Dynamics," by Mr. Ll. B. Atkinson, will be delivered at the Finsbury Technical College on November 30 at 8 p.m.

South London Railway.—The *Standard* gives vent to the complaints of correspondents on the overcrowding of the South London Electric Railway on Saturday afternoons and other times. We are pleased to see this sign of the times: it certainly shows the line is appreciated; and what suburban line, we should like to know, is not crowded at special times! All the same, as the traffic goes up the trains will have to be increased in number.

Niagara.—The large tunnel for the tail race at Niagara Falls has now been finished. The engineers expect to have the turbines and the rest of the plant ready for running in March next year. The plant will be capable of yielding 75,000 h.p., and as Buffalo is estimated to take only 45,000 h.p. at present, there will be sufficient to replace all existing engines in Buffalo, and still leave 30,000 h.p. for transmission elsewhere—Chicago possibly among the rest.

Turin.—A bold project is being brought to the practical point by two Italian engineers, MM. Aguidio and Azari, for transmission of force to Turin from a waterfall on the Italian side of Mont-Cenis, 40 miles distant. A power of 4,000 h.p., by means of four vertical turbines, is spoken of, the force to be transmitted electrically on six bare overhead copper cables to Turin, following the railway of the Susa Valley. The cost of the project is given at four million francs.

Book Received.—We are pleased to note the issue of the fifth edition of that well-known scientific classic, "A Hand-book of Electrical Testing," by H. R. Kempe (Spon and Co., London). A considerable amount of new matter has been added. Tables by Messrs. Glover and Co. have been inserted, as well as recent submarine cable data by Mr. Herbert Taylor. The work now extends to 576 pages. We have also received "Electric Shiplighting," by J. W. Urquhart (Crosby Lockwood and Son), illustrated.

Fire at Carnaby-street Station.—At 10 o'clock last Friday night several calls reached the fire brigade stations for Carnaby-street, Golden-square, and the news was speedily circulated by telephone that the basement of the premises of the St. James's Electric Light Company in that thoroughfare was on fire. Several engines were despatched to the scene, and with the aid of a hydrant the mischief was restricted to the portion of the premises in which it had originated. Much damage, however, was caused.

Electricity at Kensington.—A well-attended *conversazione* was held on the 17th inst. at the Kensington Town Hall, Lord and Lady Chelmsford receiving the guests. By invitation, some recent advances in electric lighting and cooking were illustrated by Messrs. Faraday and Son and Messrs. Crompton and Co. The first-named firm showed a series of artistic fittings, including many of the new devices for shading the over-brilliancy of the filament, while Messrs. Crompton demonstrated that elementary cooking and heating can be performed wherever the mains for lighting are available.

Anthracite.—The electrical engineer is doing his level best to obviate dust, dirt, smoke, and fog, and in so doing is acting as a veritable benefactor to humanity. But it will be some time till he can have houses heated by electric fires, and perhaps the next best thing he can do until this good time comes is to recommend and burn anthracite coal. An association for the promotion of the use of this smokeless coal is formed, with offices at 18, Parliament-street, and showrooms at 121, Regent-street, and the promoters, though working in a slightly different field, should have the goodwill of all electrical enthusiasts.

Coast Communication by Telephone. — The Admiralty have issued instructions to the Post Office authorities to connect Peterhead and Fraserburgh and the coastguard stations *en route* by means of telephone. The route of communication will be from Peterhead through St. Fergus to Rattray Head Coastguard Station, thence to Inverallochy and Cairnbulg Post Office and Coastguard Station. It is understood that public messages will be allowed between Fraserburgh and Cairnbulg, and possibly St. Fergus; but only Admiralty messages will be transmitted meantime between Peterhead and Cairnbulg.

Electric Traction in Paris.—The trials of Compagnie des Tramways at Paris with electric cars seem to have proved very satisfactory. The company has adopted accumulators of the Laurent-Cély-Sarcia system. The new cars have seats for 56 passengers, with roof seats. They have independent truck bodies, and each axle is fitted with a 15-h.p. motor. The cars, which can be run together in trains, run at eight miles an hour in Paris and 10 miles outside the fortifications. Each car is furnished with a special apparatus to derail the cars so as not to interrupt the traffic when the road is obstructed by accident. A powerful electric brake enables the car, by reversing the current, to be stopped within three yards.

Sulphide of Carbon.—The Baxeres-Torres process of producing sulphide of carbon consists, says the *Revue Industrielle*, in passing through a mass of carbon of any kind—coke, gas, carbon, etc.—brought to incandescence by a number of variable arcs, sulphur vapours produced by heating in the same apparatus some sulphurated substance—sulphur, sulphurated earths, pyrites, sulphates, particularly sulphate of baryta, sulphurated residual products, among others the brick ashes of soda. A series of arcs can be used operating simply by the high temperature produced to volatilise the sulphur, when this is possible, or by acting both by dry electrolysis and calorific effect on the product treated. The operation is for the purpose (1) of producing the isolation of the sulphur from the combination in which it is found, (2) producing the volatilisation of this sulphur when rendered free.

Bazaar Lighting.—A very successful bazaar was held last week at the Vestry Hall, Turnham Green, in aid of the funds of St. Alban's Church, Acton Green. The Dowager-Countess of Winchelsea and Nottingham, in the presence of a numerous company, performed the opening ceremony. The stalls were tastefully illuminated with incandescent lamps, the current being derived from accumulators, the whole of the electrical gear having been lent by Mr. Ronald A. Scott, M.R.I., of Acton-hill; whilst the installation was carried out by Messrs. Worthington, Leslie, Bigland, and Denny, under the supervision of Mr. Cyril Davies, all being members of the Acton Hill Engineering Works, and who kindly gave their services. Owing to a ball on the previous evening the work had to be carried out during the night. Lady Winchelsea expressed herself as

in the healthiness of the air. Whether such an arrangement would be desirable in the British Museum or not, it is certainly necessary in a place of this national importance that no complaints should arise about the ventilation, and we trust the authorities will be able to pay a little attention to the matter.

Liverpool Polytechnic Society.—The seventh meeting of the fifty-fourth session was held at the Royal Institution, Colquitt-street, on Monday evening, November 21st, Mr. Thos. L. Miller, Assoc.M.Inst.C.E., president, in the chair, when a paper on "Electric Traction" was read by Mr. Francis G. Baily, B.A., A.M.Inst E.E., of University College, Liverpool. In opening the paper, Mr. Baily gave an historical account of the application of electricity as a tractive force, and drew attention to the early attempts with primary batteries. A description of the various methods of traction by accumulators and by collectors and leads then followed, and examples were given of their application to trains, trams, 'buses, launches, tricycles, travellers, telpherage, etc. The methods of using accumulators were then dealt with, together with their advantages and cost, and the direction of future improvements pointed out. The collector method was then dealt with, and the limits to its use pointed out. Overhead collectors and the third rail were then referred to, and descriptions of various lines and results of working given. Comparison of the various methods in efficiency, convenience, and cost then followed, after which descriptions of the electric motors used and designs required were given. The methods of regulation were explained and the amount of power used was dealt with. The general advantages of electric traction were then considered, with its dangers and the precautions to be taken against breakdowns, and the paper concluded with an account of some of the new schemes proposed and a forecast of the lines of future advance.

Siemens and Halske Electrolytic Zinc Process. The process of obtaining zinc electrolytically adopted by Messrs. Siemens and Halske, has for its chief purpose the prevention of the zinc being deposited at the negative pole in a spongy form, consequent on hydrogen being also disengaged. For this purpose the electrolyte formed of a neutral or slightly acid solution of sulphate of zinc obtained in any usual manner by treatment of zinc ore, has added to it either (*a*) a weak solution of chlorine, bromine, or iodine; (*b*) a weak solution of hypochlorous or hypobromous acid; (*c*) a current of chlorine gas or bromine gas is sent into the solution; (*d*) or a soluble organic compound of chlorine or bromine is added, which, under the influence of the nascent hydrogen, can give up all or part of the haloid element, such as the chlorhydrine or bromhydrines of glycerine or certain glycols; (*e*) lastly, two or several of the reactions above-mentioned may be used. The proportion of zinc-hydrogenium or of nascent hydrogen which is produced electrolytically from the sulphate of zinc, causing the spongy deposit of metal, is relatively very weak. So that small quantities of the halogen element, or of its substitutes, are sufficient to produce a coherent deposit of zinc; and the action of the chlorine, bromine, etc., on the metal deposited at the cathode during the passage of the current is altogether negligible. At the commencement of the electrolysis a small quantity of the halogen element is added, renewing the dose from time to time, so that during the whole operation the electrolyte always presents a weak though distinct reaction. Under these conditions, instead of obtaining, especially at the commencement, a deposit of pulverulent grey metal, there is obtained from the moment of starting a coherent metallic coating of silvery-white colour and crystalline structure.

Units and Quantities.—M. Hospitalier, in an article on "Units, Dimensions, and Quantities," in *L'Industrie Electrique* recently, has the following passage: "English electrical engineers commit a fault in defining magnetic induction as the number of lines of force per square centimetre. In acting thus, a physical quantity and a unit are associated together; the product being a hybrid, neither physical quantity nor unit, whose least inconvenience is to falsify entirely right ideas of the relations between physical quantities, and to establish an inextricable confusion between the physical quantities and the units that serve them as common measures. For the same reason there only ought to enter into the definition of a unit of measure of a given quantity units of quantities which define this quantity. English electrical engineers persist, for instance, in expressing specific resistances in ohms per centimetre cube, under the pretext that the specific resistance of a substance is the resistance of a cube of 1 cm. each side between the two opposite faces. But a specific resistance cannot be measured in ohms per cm.^{3}; it is the product of a resistance by a length, and should be measured in ohms-centimetre. These general ideas are unfortunately almost always wrongly conceived, and it is for this reason that we so often see, even in the reports of the most scientific societies, speeds and accelerations in metres, specific resistances in ohms, and so forth. The International Congresses, adds M. Hospitalier, "would do a great and useful work by formulating, once for all, the general rules which should preside over definitions, for once these rules were settled, the special definitions would then only be natural, logical, and systematic consequences, of which the application could be indefinitely extended, to respond to the new needs of science and physical industries."

Electric Light Fires.—The practical organ of the fire insurance offices, the *Review*, has last week a first article on "Electric Light Fires," with practical illustrations. The article consists of examples, culled from here and there, of fires and other accidents resulting from electricity, from the Grosvenor fire to a shock from a gas and electric combination. There does not seem to be much attempt at classification, and some of the instances are amusing—thus: "Hatter's shop—arc light, iron resistance frame tampered with." It reminds one of the couplet, "Boy, gun, joy, fun; gun bust, boy dust." An interesting example is given, contrary to usual experience so often quoted, of a hosier whose goods were set fire to by an article falling on an incandescent lamp. Lest the unbelieving should revile, it is stated this happened twice. Examples introduced by "It is currently reported,' will not do for such a list. The instances ought to be well vouched for, and above reproach. The following sensible remarks are given *apropos* of pendant lamps: "There is a good deal of danger in connection with pendant incandescent lamps. The multiplicity of fine strands which constitute a pendant wire, the two wires also being so close to each other, makes it exceedingly easy for a fine filament of copper being left out of place in the holder, to set up a short circuit, burning out the fuse. Now the real danger comes in. Where the fuse is gone it is probably mended by a piece of copper wire of substantial thickness, and there you are, as the saying is." Moral: Give full instructions as to fuses, and see that they are obeyed. The *Review* also strongly advises periodical testing for leakage and continuity and for the examination of state of the fuse, switches, and all fittings. It is suggested that the inspector should particularly enquire on his visits with reference to apparent discrepancy between meter readings and number of lamps used, the abnormal destruction of lamps, or the variation of their brilliancy.

A Plea for Exactness.—Scientific progress is made by two methods of working, experimental and theoretical. The two are both potent, but are entirely different in kind—one deals with facts and the other with thoughts. The statement of experimental facts when proved and tested are true for all time, but the theories often change from one year to another. The writers of scientific text-books and technical articles do not seem to thoroughly realise this point, and their statements of what really exists or happens, and what is supposed upon theory to happen, are nearly always given with the same certitude of diction. "A piece of soft iron energised by a coil of wire connected to a battery will attract iron." This is a fact. "The ether is an imponderable substance existing everywhere" is not a fact—it is a supposed fact, invented to explain the action of light and electricity. Beginners in the study of electricity and kindred scientific subjects experience more difficulty than professors are willing to admit in differentiating actual from hypothetical facts. The text-books usually sin greatly in not discriminating, as they certainly should, between these two different kinds of statement. In electrical science the "ether" is the centre of most of these hypothetical statements; but when discussion is raging round a theory, when even the theory is firmly settled, until actual experiment can demonstrate the facts are as stated, would it not be better that the words "are supposed to" be or do this or that—or an equivalent hypothetical method of expression—should be used by all writers with a pretence for scientific exactness? The text of this plea for exactness in scientific statement has been given by a quotation in a technical journal from Prof. Oliver Lodge, whose definition of ether is given, commencing, "Ether is," but defining what the latest theories conceive ether to be. This attitude of mind runs through the whole scientific world, more particularly with the teachers, and a glance into any book on science will show many statements made as facts which are certainly theoretical only. Let us clearly recognise this difference between objective facts and the subjective reasoning from these facts, keeping in all discussions, and more especially in text-books, the two absolutely distinct.

Marseilles Electric Tramway.—The electric tramway recently established at Marseilles runs from La Cannebière to Saint-Louis. The generating station is placed in a new depôt erected by the tramway company at Lazaret. Three multitubular boilers by Naeyer evaporate 1,100 to 1,500 kilogrammes of steam per hour, driving three Hoffmann vertical compound engines, 100 h.p. each, running at 300 revolutions. Each engine drives a dynamo of 66,000 watts at 550 volts. The dynamos are two-pole compound wound, with ring armature. The engines were made by the Oerlikon Company, and the dynamos by MM. Sautter Harlé, of Paris. Two sets are sufficient for the service of 12 or 14 cars, the third being for reserve. A separate set made by Oerlikon produces light for the station. The cars were made by the tramway company. They carry inside passengers only, and have switches at each platform. Each axle is driven by a 15-h.p. motor by means of an endless screw acting on an helical wheel. The speed of the motors is 1,400 revolutions when travelling at 20 kilometres (12½ miles) an hour. The starting and stopping are easy and gradual under the action of the switch-lever. The cars are brilliantly lighted with three 16-c.p. lamps, and head lamps on each platform. The gradient of the line is very uneven, the greatest rise being 5·9 in 100 for 90 yards. At Saint-Louis there is a curve of 16 yards radius on a rise of 5 in 100. The cars pass these places at eight to twelve kilometres (5 to 7½ miles) an hour. At other points the speed does not usually rise above 14 kilometres (eight miles) an hour on account of the traffic, but at night the cars have been run at a speed of upwards of 25 kilometres (15 miles) an hour. The length of the line is six kilometres (3¾ miles), all double line except in one street. It is divided into four sections, each served by special overhead feeders. These are connected to the switchboard by an automatic cut-out, which interrupts the current in any case of breakage of the overhead wire or short circuit. The feeders are insulated in the neighbourhood of houses and telephone lines. They are supported on oil insulators. The trolley wire is carefully insulated by suspension pieces fitted with ebonite, and the carrier wires placed transversely across the public street are insulated from the poles and buildings by porcelain insulators carried on paraffined wood. The effective work at the ends of the line is over 50 per cent. of the power produced at the pulleys of the engines. The return circuit is made by the rails, and by an underground network of galvanised iron wire. The connection of rail to rail is effected by slotted rivets and copper wires. The contract has been carried out in combination by the Oerlikon and Sautter-Harlé Companies. The price of traction guaranteed is not to exceed 0·22f. (say, 2d.) per car kilometre (say, 3½d. per car mile) for a daily run of 1,200 kilometres, or 750 miles.

Lighthouse Communication.—It is very satisfactory to see the great attention which is now being paid to electric lighthouse communication. The interesting letter by Mr. W. H. Preece to the *Times*, which we reproduce in another column, was followed on the 24th by an equally interesting communication from Mr. Willoughby S. Smith, who states that before the year 1887 his father, the late Willoughby Smith, has carried out successful experiments with the object of communicating electrically through water to lighthouses or ships. When Sir Edward Birkbeck moved for a Royal Commission on the subject, the suggestion was made by Mr. Willoughby S. Smith to Admiral Sir George Richards and Mr. W. Shuter, of the Telegraph Construction and Maintenance Company, that the experiments should be repeated in order to show the practicability of such a system. Application was made to the Trinity House, and the Needles lighthouse was kindly placed at their disposal to carry out the trial. The writer continues: "With my assistant, Mr. W. P. Granville, I carried out experiments upon the original ideas and introduced certain modifications in the arrangements, with the result that constant communication has been maintained between the lighthouse and the shore in both directions since June last, the instruments being worked by the lighthouse keepers. I did not publish any statement as to this successful installation, because having practically carried out the trial for the information of the Royal Commission, I considered it would be quite time enough to speak more fully when the report had been made, which would probably include the evidence given by me on the subject. To briefly describe the arrangements at the Needles, I may say that an ordinary submarine cable has been laid in Alum Bay to within 60 yards of the Needles rock, where it terminates, with its copper conductor attached to a small anchor; the anchor is in 5½ fathoms at dead low water, and is quite free from any action of the waves. The shore end of the cable is attached to the signalling instruments, while to establish the circuit a simple earth-plate is immersed in the water close to the shore. On the lighthouse rock two strong bare wires dip into the sea about 10 yards apart; these two wires are in connection with the signalling instruments in the lighthouse. Thus, through the inter-

vening space of 60 yards of water the men on the rock can call the attention of those on shore, or *vice versâ*, by means of an electric bell, and communication can be established by means of a single Leclanché battery cell, which seems simpler than a powerful generator, to say nothing of the half mile of wire on the lighthouse rock, a thing impossible in most instances." The writer inclines to the idea that Mr. Preece has been doing work similar to that previously done in Alum Bay, but the methods appear less simple. The working of the system briefly described above has been inspected by the members of the Royal Commission, who sent from the lighthouse a message to their chairman, the Earl of Mount Edgcumbe, then at Osborne.

Cost of Electric Welding.—Mr. Frederick P. Royce in a paper read at the Buffalo Convention of the Chicago Builders' National Association, reproduced in the *Electrical World*, discusses the practical question of the comparative cost of electric and forge welding. The two important elements are labour required at the welder and necessary power to drive dynamo—the attention at the dynamo being slight. One man only is needed for light and regularly-shaped pieces. When great rapidity is necessary a boy or assistant will be required. In case of axle work two men are needed, a blacksmith and a helper turning out easily 150 sets of 1in. axles or 100 sets of 1½in. axles. In the case of light iron tires one man can easily weld 700 to 800 daily with a cheap helper to carry. In the case of steel tires 400 to 500 can be welded. In heavy wagon tires more help is needed. At the Studebaker works two electric welders are placed side by side, with a steam hammer near, and a force of five men turn out a large product. Step-irons, carriage rails, dash-irons, and similar work is done by one man. The removal of the burr at the joint is an element of cost. Grinding is too slow, and rolling is impracticable. Hammering has been found to be the cheapest and most effective. All welds retain sufficient heat to be hammered, and this also improves the weld. With ordinary work the light hand-hammer is most effective. Presses have also been found efficient. Cleaning the metal before welding has been abandoned, it being cheaper to use more current. When a heavy oxide is formed it is removed by pickling, but it is only necessary in exceptional cases. The question of actual horse-power required for welding both axles and tires has been most carefully considered, and the following figures are based on actual experience in various works and from very careful electrical and mechanical tests made by reliable experts.

1 in. round	axle requires	25	b.p.	for	45	seconds.
1 in. square	,, ,,	30	,,		48	,,
1¼in. round	,, ,,	35	,,		60	,,
1¼in. square	,, ,,	40	,,		70	,,
2 in. round	,, ,,	75	,,		95	,,
2 in. square	,, ,,	90	,,		100	,,

The slightly increased time and power required for welding the square axle is not only due to the extra metal in it, but in part to the care which it is best to use to secure a perfect alignment for the welding. For tire welding the figures are:

1 in. × $\frac{5}{16}$in.	tire requires	11	h.p.	for	15	seconds.
1¼in. × ⅜in.	,, ,,	23	,,		25	,,
1½in. × ⅜in.	,, ,,	20	,,		30	,,
1½in. × ½in.	,, ,,	23	,,		40	,,
2 in. × ½in.	,, ,,	29	,,		55	,,
2 in. × ¾in.	,, ,,	42	,,		62	,,

The time above given for welding is, of course, that required for the actual application of the current only, and does not include that consumed by placing the axles or tires in the machine, the removal of the upset, and other finishing processes. From the data thus submitted, the cost of welding can be readily figured for any locality where the price of fuel and cost of labour are known.

Mason College Engineering Society.—A general meeting of the above society was held in Mason College, Birmingham, last week, when a paper on "Electromotors in Factories" was read by Mr R. H. Housman. The author divided factories into two classes—(1) those in which power could be supplied from a single engine, as in a Lancashire cotton mill; (2) those in which the machinery requiring power was too scattered to enable one engine to economically drive the whole, by means of ropes and gearing. In the second case a considerable number of methods of driving might be discussed. Separate engines might be used supplied from either a battery of boilers, or each from its own; but here a loss of economy is experienced owing to condensation of steam in steam-pipes, use of smaller engines, and many other causes. He then considered the degree of economy attainable when one or more large engines were employed to drive dynamos, the current being distributed by copper conductors to motors at the various places requiring power. He pointed out that at first sight a dynamo, conductor, and motor seemed a rather expensive type of coupling, but it must be remembered that with this system of distribution it made very little difference whether the power were scattered or concentrated. In order to obtain a high standard of economy in this system it was necessary (1) that the generating plant be concentrated at a single centre, in order to economise labour; (2) the plant should be worked at or near its full capacity. For this latter reason it was often necessary to depart from the ideal system of one large engine and generator, and use several smaller engines and dynamos, the best number to be employed depending on the variation of load caused by the special work which has to be done in the factory. He next considered the amount of variation of load allowable in various cases. In the case of an engineer's machine-shop the ratio of maximum to minimum load might be taken as 3 to 1; but in some cases, where very sudden variations of load were experienced, as in rolling mills, the ratio might rise as high as 20 to 1. The advantages of the use of heavy flywheels for dealing with load variations was pointed out, but a more perfect though less simple method was to use a battery of secondary cells in parallel with the generating dynamo. The next point considered was the efficiency of the motors. The author's experience gave 94 per cent., 91 per cent., and 83½ per cent. efficiency as averages for full, half, and quarter loads. The author alluded to the series of experiments carried out by Mr. Willans, which gave a complete key to steam engine efficiency under varying loads, and showed the disastrous effect of underloading, especially with simple non-condensing engines. Electromotors suffered much less in efficiency when partially loaded, it being possible with care to obtain 70 per cent. of the steam engine indicated horse-power as brake horse-power at the motor shaft, this showing about 30 per cent. in the double conversion and transmission. In the motors used for factory purposes it was necessary that the motor should run without requiring special attention, and should not spark with variation of load. The use of carbon brushes obviates this. Another difficulty encountered was the high speed at which motors were run. This, however, could be got over by using multipolar machines. The paper was followed by a discussion, in which Messrs. R. Richardson, F. W. E. Jones, E. C. R. Marks, T. Archer, H. M. Waynforth, and Prof. R. H. Smith took part; and the proceedings terminated with a vote of thanks to the author.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

(Continued from page 509.)

RESISTANCE, *continued.*

Other Forms of Wheatstone's Bridge.—Another arrangement of the rectangular pattern of Wheatstone's Bridge, made by Messrs. Queen and Co., of Philadelphia, and differing but slightly in general principle from Dr. Muirhead's design, although varying considerably in point of mechanical construction, is shown in Fig. 23.

FIG. 23.—Wheatstone's Bridge, Queen's Pattern.

In this instrument each set of coils in the variable known resistance has its junction-pieces arranged on one side only of the long metallic bar, instead of on both sides, as in instruments of Dr. Muirhead's pattern. The chief feature in the instrument, however, is the arrangement of the coils in the two ratios, which are so devised that with three coils in each arm, there are obtained all the variations usual with four coils in each. This is accomplished by making the coils in the two arms of different values, and providing a reversing arrangement, so that the virtual positions of the two arms may be interchanged. In the example shown, the resistances of the coils in the two arms are respectively:

1,000, 100, 10,
and 100, 10, 1 Ohms,

and the reversing arrangement, the principle of which will be readily understood from the figure, is a very simple

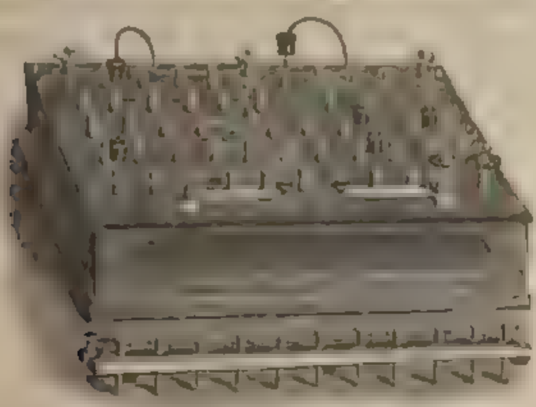

FIG. 24.—Wheatstone's Bridge, Paul's Laboratory Pattern.

one, the operation of interchanging the positions of the two ratios consisting merely in the alteration of only two plugs. Of the six terminals shown in the illustration, the two on the right hand side are for the galvanometer, and the two outer ones at the left hand side are for the battery, the unknown resistance being connected to the two inner terminals at the left hand side. It will be observed that, in this example as well as in the three succeeding ones, the galvanometer and battery keys are incorporated in the instrument itself.

Two examples of another form of combined Wheatstone's Bridge and resistance box, of the same type as the preceding ones but possessing several important modifications, are illustrated in Figs. 24 and 25. In these examples, due to Mr. R. B. Paul, the junction pieces of the coils consist of round metal sockets arranged in rows on the ebonite baseboard, and connection is made to them by means of flexible insulated conductors, one for each group or row of coils. Each of these flexible conductors has one of its ends permanently attached to the first coil of one of the rows, whilst the free end is provided with a taper plug for insertion into any of the sockets in the junction pieces in the next row of coils, contact in this way being established between two rows of coils by means of the flexible conductor. These

FIG. 25.—Wheatstone's Bridge, Paul's Portable Pattern.

these flexible conductors, each of which consists of from two hundred to three hundred strands of fine copper wire, fulfil the same function as does the round or oblong centre-piece in the dial or rectangular forms of the instrument. In both of the examples shown, Figs. 24 and 25, the underboard connections are indicated by white lines on the baseboard, so that no difficulty need be experienced in connecting up, or using the instrument. Among the advantages claimed for this form of instrument are: Surface leakage across the ebonite baseboard is reduced to a minimum owing to the junction pieces being some little distance apart, and these are easily cleaned; contact resistance is constant and easily measured and allowed for; much better contacts are

FIG. 26.—Wheatstone's Bridge, Swinburne's Pattern.

obtained as the plugs bear on the sockets all round instead of only on a portion of their circumferences. The sockets being made each in one piece are not liable to deformation through unequal expansion of metal and ebonite, as in the ordinary form of instrument; and the plugs being permanently attached to the instrument are not liable to get lost or mislaid.

The instrument illustrated in Fig. 24 is also provided with a special contact-bar as shown in the illustration, whereby any number of coils in a group may be coupled up in parallel, thus converting the instrument into a high range conductivity box, suitable for the measurement of very low resistances. The construction and principles of

mentioned, animal electricity, as the torpedo, gymnotus, and other electric fish. Lastly, there is atmospheric electricity.

Of the four practical generators of electricity—namely, the Primary cell, the Thermopile, the Dynamo and the Secondary cell—the last must be disregarded, because in the present way in which secondary cells are made, electrical energy has first to be put into them, and so converted into chemical energy, before they can be utilised to give out electrical energy. Concerning the primary cell, this is too expensive and impracticable, as shown in the paragraph on "Sources of Power." As for thermopiles, attempts have been made to construct these on a large scale, so as to make them powerful enough to run electric lights, but so far they are not classed as being of practical use. It is possible that in the future better things may be expected of this source of electricity, and it is interesting to note that, by means of a thermopile, an example is afforded of generating electricity direct from heat, and hence from burning coal, without any intervening converters. To what extent this will become practicable, it is impossible to say; the subject is, however, worth research.

Having disposed of three, we thus have only one practical source of electricity available from which to obtain electric light and power on a large and commercial scale, and that is the "Dynamo."

Water Analogy.—The simple laws regulating the flow of electricity along a conductor can best be made clear and comprehensible by comparing them with those regulating the flow of water in pipes. It must, however, be remembered that the analogy between electricity and water cannot be strained and carried too far. This water analogy is a time-honoured one, and although modern theories and speculations concerning the nature of electricity and its attendant laws, as taught to-day, are different to what were taught in the old schools, yet, for all we know respecting what electricity is, the water analogy still holds good.

In the case of water a flow is produced by a difference of level, consequently a head is created; the greater the head or pressure the quicker the flow, and the greater will be the quantity of water that will flow through the conveying pipe. By decreasing the diameter of the pipe more resistance will be offered to the flow and by increasing the diameter less will be offered; the pressure of the water, and hence its velocity, will gradually fall off along the length of the pipe, and if the pipe be made very long the pressure will be reduced so much that the water at the far end will scarcely move along. We will now see how this can be applied to electricity flowing along a wire.

1. The pressure or difference of level of the water may be likened to the E.M.F., or "Difference of Potentials," that tends to move electricity; the greater this is, the greater is the flow of electricity.

2. The size or diameter of the pipe may be likened to the diameter of the conducting path or circuit. Water flowing in a pipe produces friction, and hence heat, and this is energy wasted, so a current of electricity flowing along a wire, or other conducting path, produces what may be termed electrical friction, and this also produces heat, and hence wasted energy; by making the conducting path of greater capacity, say, by increasing the diameter of the wire that forms the circuit, a greater current of electricity will flow.

3. The lengthening of the pipe may be likened to the lengthening of the conducting path or circuit: if the wire composing the circuit be made very long, the electrical potential will fall along the circuit. In the case of water the effect of a long pipe means that a great quantity flows by at the beginning of the pipe, while scarcely any flows by at the end; in the case of electricity this does not hold, for the effect of a long circuit on the flow of current is that very little current will flow, and that, however much it is, the amount of current that flows is the *same quantity passing at every point of the circuit*.

4. In the case of water, the effect of having a pipe of varying size or diameter at various points, is that at those points where the diameter is small only a small quantity of water can get through at a time, while at those points where the diameter is large a large quantity can pass; but when the pipe narrows the velocity increases, and when it widens the velocity decreases; consequently, the product of the sectional area and the velocity at any point will be constant. Now, in the case of electricity, as already stated, the current is always the same at every point in the circuit, and the effect of having the conducting path narrow at some points and wide at others would not cause the current to vary at these points. What would take place is this: At the narrow points more heat would be generated by the flow of current, and at the wide points less heat would be generated.

5. Water, to be carried a long distance, must have very great pressure, and the quantity must be necessarily small, hence a long thin pipe of small diameter must be used.

Electricity, to be carried a long distance, must have very great E.M.F., and the quantity must be necessarily small, hence a long thin wire of small diameter must be used.

In a water system, the initial or maximum pressure decreases as the water flows on, and in an electrical system or circuit, the initial or maximum electrical potential also decreases as the current flows along the conducting path. In each case this is owing to the resistance that is met with; and the "difference of pressure" and "difference of potential" that exists between any two points of the two systems measures the loss of pressure or potential, or the amount that is absorbed in forcing the water or electric current through the distance between these two points, and so overcoming the mechanical or electric friction for that distance.

Water is a material body, whilst electricity is looked upon as a peculiar state or condition of matter—what, we do not know. We even do not know in which direction a current of electricity really flows, although for convenience it is arbitrarily assumed that it flows from the point of higher potential to the point of lower potential. Furthermore, we do not know that its action is propagated inside the wire or not; to every appearance its action takes place around the wire or conducting path, and the wire may be looked upon, not for the purpose of carrying the current, but of guiding it.

In a simple electric circuit there can only be one electromotive force, and this is called the initial or maximum difference of potentials; but there can be an infinite number of difference of potentials. For example, a battery may have an E.M.F. of 50 volts—that means the maximum difference of potential is 50 volts—and allowing the current to flow from the positive plate to the negative, the potential will gradually fall all the way around the circuit, beginning at the positive plate and ending at the negative; so that any two points in the circuit will represent a difference of potentials in proportion to the distance between, provided that the resistance of the external circuit is uniform throughout.

Electrical Units.—The practical unit of E.M.F. is named the volt, and is that amount of electrical pressure that will force a current of one ampere through a path having the resistance of one ohm. Volts are usually denoted by the letter E. Since the E.M.F. may also be looked upon as the maximum difference of potential in a circuit, hence the volt is the unit of difference of potential. Measured in absolute, or C.G.S. units, the unit signifies that E.M.F., or difference of potential, which is necessary to force a unit quantity of electricity per second from the point of higher potential to the point of lower potential, so that the current does one erg of work per second. This can be made clearer by referring to our water analogy. When a certain mass of water falls from a higher level to a lower level, then work is done by the mass; so that 10lb. falling 10ft. will do 100 foot-pounds of work. Similarly, when 10 units of current flow from a potential of 90 to a potential of 80, or through a difference of potential of 10 units, then 100 ergs of work per second have been done by the current. Also one erg of work is done by forcing a unit current through unit resistance because it requires unit difference of potential to do this, and because the amount of work that is expended in doing this—namely one erg—is evidently equal to the amount of work—one erg—done by the current. This absolute unit of potential difference is far too small for

practical purposes, hence the practical unit of potential difference, or E.M.F.—namely the volt—is fixed equal to 10^8, or 100,000,000 times the absolute unit.

The practical unit of current is called the ampere, after Ampere, a French physicist, and is that current which one volt will force through a resistance of one ohm. The absolute unit of current has a value of 10 C.G.S. units, and is too large, so the practical unit, the ampere, is equivalent to one-tenth of the absolute unit, and is generally denoted by the letter C.

The practical unit of resistance, denoted by the letter R, is named the ohm, after Ohm, the famous German physicist, who discovered the elementary law connecting pressure, current, and resistance, and is that resistance which when acted upon by a difference of potential of one volt will permit a current of one ampere to flow through it. The absolute unit of resistance is too small, so the practical unit, the ohm, is made equal to 10^9, or 1,000,000,000 times the absolute unit, and according to the Paris Congress of 1884 the ohm is the resistance of a column of pure mercury, one square millimetre (or ·0016 square inch) in sectional area, and 106 centimetres (or 41·73in.) in length, measured at the temperature of melting ice.

Ohm's Law.—The amount of current which will flow in an electrical circuit depends on the E.M.F., which urges the flow, and on the resistance of the material forming the circuit, which tends to obstruct or oppose this flow.

The flow of current is in proportion to the E.M.F., therefore the greater the E.M.F. the greater the flow; it is also in inverse proportion to the resistance, so that the greater the resistance the less will be the flow of current; hence we have

$$\text{Current} \propto \text{E.M.F.}$$

$$\text{Current} \propto \frac{1}{\text{Resistance}}.$$

Combining these two facts together, it is evident that

$$\text{Current} \propto \frac{\text{E.M.F.}}{\text{Resistance}};$$

hence we may say that the current flowing in a circuit is obtained by dividing the E.M.F. by the resistance,

$$\text{or,} \qquad \text{Current} = \frac{\text{Electromotive Force}}{\text{Resistance}},$$

$$\text{or,} \qquad \text{Amperes} = \frac{\text{Volts}}{\text{Ohms}}, \text{ or } C = \frac{E}{R}.$$

By multiplying the resistance of a circuit by the current, we obtain the E.M.F. necessary to force that current through that resistance, or E.M.F. = current × resistance, or volts = amperes × ohms, or E = C × R. By dividing the E.M.F. by the strength of current flowing in the circuit we obtain the resistance of the circuit,

$$\text{or,} \qquad \text{Resistance} = \frac{\text{Electromotive Force}}{\text{Current}};$$

$$\text{or,} \qquad \text{Ohms} = \frac{\text{Volts}}{\text{Amperes}}, \text{ or } R = \frac{E}{C}.$$

The above is known as Ohm's law, and it is the fundamental law of electricity, since it establishes the relation between E.M.F. and current and resistance.

Currents are divided into several kinds, according to the construction of the electric machine which generates them, such as continuous currents, alternating currents, pulsating currents, multiphase currents, etc.—each of these will be treated with and explained later on. For the present it suffices to say that the first kind—namely, continuous currents—are known as steady currents, because the effective E.M.F. producing them is practically constant in value, but the rest are unsteady, because the E.M.F. is constantly varying or falling and rising in value. Ohm's law, in its above simple form, is absolutely true for all steady currents, and we have every reason to believe that it is true for all unsteady currents as well, but when applied to unsteady currents, say, for example to an alternating current, then the flow of current in amperes cannot be found by simply dividing the volts of pressure by the pure ohmic resistance of the wire carrying the current, because the effect of the pressure constantly varying is to produce currents of a secondary and tertiary nature arising from self induction and mutual induction, etc. In addition to this, an alternating current flows first in one direction and then in the opposite, alternately, a great number of times per second. This brings in more complications, because the flow of current offers a certain opposition to change of direction, which is named the inertia of the current, in comparison with the inertia in mechanics. All these disturbing elements must be recognised, and, if possible, be subjected to calculation. It need scarcely be said that when this is done the complicated formula that would be presented would probably be such that Ohm's law in its simple form would be almost lost to sight; so that when Ohm's law is applied, it must be understood that it is only used for steady currents, except when otherwise stated. For those that are interested in this matter, see the *Electrical Review* of May 20, 1892, page 626.

(To be continued.)

THE INSTITUTION DINNER.

The annual dinner of the Institution was held at the Criterion Restaurant on Friday evening last, and was attended by a large number of members and guests. Prof. W. E. Ayrton, F.R.S., the President, was in the chair, and was surrounded by a distinguished company of politicians and scientists. The toast list was short, as were the majority of speakers. We have seen Prof. Ayrton in a great many characters, but we think in none has he ever shone more conspicuously than in these after-dinner remarks. They were full of point and full of wit, with the true ring of enthusiasm for the science he so admirably represented, running through from beginning to end.

The toast of "The Queen" was given and received in the usual loyal manner. The next toast, "The Learned Societies," was proposed by the President, who said that some difficulty had been felt in the wording of the toast list. It was thought that to have two toasts—"The Learned Societies," "The Engineering Societies"—might suggest that the latter were not learned. But the inference would be entirely wrong. There was no "and" in the matter. His friend Mr Macrory, as a lawyer, would tell them that the French saying "None but fools and Englishmen travel first class," was evidence that Englishmen were not fools. The presence of the conjunction made all the difference.

Prof. FITZGERALD responded in a partly humorous and partly grave speech. In the former he gave an admirable description of a discussion between two Irish car drivers as to the merits of scientific men which ended in "going for a drink." He said that the learned societies were never more flourishing than they were now. The co-operation of theory and practice had been the fruitful parent of nearly all the advances of the present generation. We had such enormous stores of energy at our service that almost immeasurable prospects were open for the material improvement of man's estate.

Mr. LATIMER CLARK (past president) proposed "The Engineering Societies." He said these societies were in danger of being overlooked. They first perfected the steam engine, then improved manufacturing implements, then the steamboat. The engineering societies had done much more to promote the great prosperity of this country than the politicians who had so wickedly usurped the greater part of the credit. The great majority, unfortunately, of our countrymen believed that this prosperity was mainly due to the politicians who attributed everything to free trade. It was to the engineers more than to any other body due that this country was the richest in the world.

Dr. W. ANDERSON, president of the Mechanical Engineers, responded, and said if the engineering societies were

not learned they had the happy gift of appropriating for practical purposes the learning of others. The Government factories, of which he was the head, could speak to the way in which the labours of the chemist and metallurgist and other scientific men were utilised to practical purposes to the great benefit of this country, and, it was to be hoped, the destruction of any country which should be so ill advised as to become involved in war with Great Britain.

The CHAIRMAN then proposed "Our Guests," with which he joined the name of Mr. Mundella, President of the Board of Trade, who exercised a sort of parental supervision over them all. No doubt sometimes there was a little disposition to grumble, as children did occasionally, at the form in which that fatherly affection displayed itself. But whatever their feelings about the Board of Trade, there was no doubt about their feelings with respect to its president. The man who by the Electric Lighting Act, 1888, made electric lighting commercially practicable was entitled to their warmest regard.

Mr. MUNDELLA, in response, said that whatever grievances the engineers might have against the politicians his withers were unwrung. The Board of Trade might have given the electrical engineers some trouble; if so, it was not due to him. He was only newly installed—only three months—and some of them might think he would not last much longer. The President had thanked him for what he had done in 1888. But he was not then President of the Board of Trade. He had, however, learnt that the Act of 1882 was too restrictive and required relaxation. But they had not suffered much from the Act of 1882, which was probably only a blessing in disguise, as it had enabled the engineers to perfect their methods in a manner which could not have been done before. Mr. Latimer Clark had complained of the appropriation of all the credit of material progress by the politicians. Let them halve the difference. The politicians had, at all events, appointed Dr. Anderson. The improvements to which Dr. Anderson had referred related to the destruction rather than the conservation of human life. But, whatever they were, the British Navy had availed itself of all those appliances, and had been enabled—we hoped for defence and not for attack—to perfect the methods of naval warfare more than any other nation in the world. Free trade was due to Sir R. Peel more than to any other man, and it was due to him that the energies of Watt, Arkwright, and our other great engineers had enjoyed free play for their energies. He was speaking to a comparatively young institution, but it was to one which was growing more and more and would advance to still greater degrees of greatness. The Board of Trade owed much to the electrical engineers, who had devised systems and methods of the utmost value. It would be his duty to embody the report of the committee with respect to electrical standards in a statement to the Queen. For that report they were much indebted to the society, as they were also indebted to the distinguished German men of science who had so greatly advanced our knowledge of electricity. But, as it would be his duty to submit to the House of Commons and the Queen the result of the labours of that committee, he could not do better than read it to them. It was in one sentence, without punctuation, and ran as follows: "That an alternating current of one ampere shall mean a current such that the square root of the time average of the square of its strength at each instant in amperes is unity." He had asked Sir Thomas Blomefield to explain that proposition, but that candid gentleman had admitted that he knew nothing about it. Sir Courtenay Boyle was not so candid, but he suspected that his friend Sir C. Boyle knew just as much as his colleague. He had been thanked for the Act of 1888. He believed we were now at the outset of a great advance in the science of electric lighting. Progress would be assured when they could assure shareholders of a reasonable dividend. Two millions had already been expended in the metropolis, and we might soon hope to overtake the United States and continental countries, which were, he feared, still, to some extent, in advance of ourselves. He hoped we should soon see the day when electricity would be the great motive power in all the work done by the nation. A marvellous change had been wrought by the introduction of the electric cable. When he left business 20 years ago, they had to wait replies for letters from Australia for three or four months. But now in one day all the operations could be carried through which used to require months to effect. Time and space had been annihilated. Electricity was now being used for the saving of life at sea, and Mr. Preece, one of their members, had been appointed a member of the Commission on Electric Communication with Lighthouses and Lightships. The number of lives lost in our electric systems had, he believed, only been six, an infinitesimal number compared with the loss which had been sustained in America. We had proceeded on a sound and careful system, which was economical of life, but would not fail to attain the greatest results at which it was possible to arrive. The Board of Trade had no desire to hamper the progress of electricity by needless rules, and hoped that in this, as in all other branches, science would go on its beneficent course untrammelled by any unnecessary regulations.

SIR JAMES SIVEWRIGHT, Commissioner of Public Works, Cape Colony, proposed "The Institution of Electrical Engineers." He spoke as one of the oldest members and a whilom secretary of the Institution, and described the affection towards the society the many members resident in the colony had towards it. He referred at length to the telegraphic work of the colony, which he half hoped and expected would continue to be pushed further and further into Africa, till its northern end reached Cairo. Parodying the words of the late MacDonald, he said his earlier life was spent as a telegraphic engineer, and his end should find him a member of the society, though, for the moment, he was under an eclipse, and so an outsider. He was enthusiastic in his expression of success to the Institution, and prophesied that the Institution would grow in strength and renown, and last as long as England lasted.

The PRESIDENT, who responded, said Mr. Mundella had made some joking remarks about the alternating definition of an ampere—it lacks punctuation, he says. Well, the reason is quite simple: it is a legal definition; and law processes are interminable, the law is everlasting, the law never stops. But he was no lawyer, so would come to an end, and thank them for the candid way in which they have drunk the toast so laudably proposed by Sir James Sivewright.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE NEW WESTINGHOUSE LAMP.

SIR,—It is an old saying that "necessity is the mother of invention," and, according to a description of the new Westinghouse lamp which has appeared in the technical Press, it is evident the experts of the Westinghouse Company have revived this ancient problem. And the advent of this new lamp, coming as it does just at this juncture, is one of great importance to all of us engaged in the electric lighting industry, not only in America, but in England and several other markets throughout the world wherever monopoly exists—in all of which places a reliable and cheap lamp cannot fail to command a ready sale amongst consumers, and by this means increase the demand for all classes of electrical plant. Therefore, this lamp opens up quite a new field for business, and, as constructed, it can be freely sold and used without fear of molestation from headquarters under the guise of the monopoly of Edison's patent rights covering certain claims to both lamps and holders, which actual infringements I have always maintained never had any real existence, except in the eyes of the law, and, singular to say, even on this point the views of various judges have very widely differed upon analysing the evidence placed before them in the various tribunals and sections of the Courts of England, Germany, and America. In England, for

instance, as is well known, the case was won and maintained in two actions entirely by infringements of the "Sawyer-Mann" hydrocarbon flashing process, which system the Edison and Swan Company cleverly secured, maintained, and worked in combination with Mr. Swan's latest improvements, which combined process undoubtedly enabled English lampmakers to produce and supply probably some of the best and most reliable incandescent lamps in the world. And so thought the German Courts, when they refused to give a monopoly to the owners of the Edison system in Germany. Now, having been professionally engaged in the litigation, both in England, Germany, and America, I have had special opportunities to peruse the evidence and pleadings used in each country, and I must say the tactics adopted by the Swan and Khotinsky people in Germany were sound. What did they do? They proved that Edison's early patents were unworkable without in some form or other by making lamps under the improvements and methods discovered at various dates by Sawyer, Mann Maxim, Weston, Swan, Khotinsky and others, which combination of talent, the German experts argued, gave to the world the real knowledge of how to make the modern glow lamp of the present time. And upon this basis the case was decided. The German lawyers are frequently called hard headed, but in the "incandescent lamp war" I am inclined to think they showed sound judgment, good stratagem, and a great deal of common sense in dismissing the German Edison Company's claims to a monopoly of the trade in Germany, which decision was undoubtedly a just and correct one and worthy of admiration from a legal point of view. If I remember rightly, one of the strongest points urged by the defenders in the German action was that the Edison Company *did not and could not* make a so called Edison lamp without adopting the more modern methods invented by others, and probably if the same tact and legal pleadings had been adopted and resorted to in England and America, both countries would have been able to have shaken hands with Germany over a triple defeat. And if all we hear and read in the Press be true, probably no man in the world was more astonished than Mr Edison (in the face of facts) to find himself legally declared by law "the inventor of the modern glow lamp," which very naturally he now believes himself to be. As regards myself, I think I can safely say that there is no man in the world as an incandescent lamp manufacturer who has personally suffered more than myself through my humble endeavours to produce a reliable low-resistance lamp for battery lighting purposes, which I claim to have accomplished by methods which in no way are infringment of others' rights; and I don't think the 60,000 little lamps sold by me during the four years I was engaged in the lamp industry did much harm, but, on the contrary, I claim my work did much good by the seeds sown, which work greatly assisted a very important industry of which the larger firms are now reaping the benefits. I also invented, as is well known, the fundamental patents for fancy and ornamental lamps, now so largely used for decorative lighting and illumination purposes -things which the great inventor did not do, as his entire group of patents show, and yet by the construction and twisting of our modern patent laws as now framed, declare and decide against me because somebody else invented something else of a colourable nature. It may be legally "law," but I fail to see where the justice comes in. I naturally feel somewhat strongly upon this point, as others are reaping the benefit without payment of a cent, and unfortunately all one can do is twinge and bear it. At the same time I do not blame Mr. Edison taking all that the law has given him; but I do blame the construction of the present laws, which as now constructed according to modern theory are neither civil, spiritual, or Mosaical, but which are so framed to provide for the upkeep of a select few Q.C.'s and certain professional experts who cling about their garments—all of whom grow fat on disputed patents. But reverting to the merits of the new lamp and its construction, which has many good points about it:

1. There is no brass used at the base, a very good point gained, as all metal contacts retain heat, which is well known to be a great objection to the construction of screw-capped lamps.

2. No platinum is used for the leading-in wires. This is another great advantage, calculating the cost of this commodity, the non use of which must cheapen the cost of manufacture, and, above all, legally overcome an important claim relative to the use of platinum.

3. The new lamp being a separable one, certain special parts, such as bulbs, sockets, and connectors, which in many cases can be reused over and over again; therefore old and hitherto useless lamp materials can now be converted into new lamps, and thus made to do treble work at a very small cost by remaking same (over first outlay paid for raw material). I can doubly appreciate this idea, especially as I hold the original and fundamental patents for converting old lamp material into new lamps under British patent granted me in the year 1887, for which method I have patents pending in the United States, and for which original process of manufacture I claim to be the first inventor; and I venture to say, according to recent decisions, that this process is a useful one, as it will enable lampmakers to convert old and waste lamp materials into an article of commercial value, and as royalties have been paid upon these used-up lamp materials, the question of infringement of the rights of A, B, and C, either in England or abroad, does not apply in the face of the many decisions already recorded, hence the value to those holding licenses to manufacture under my original patents, No. 5,955, of 1883, and No. 11,802, of 1887.

4. The question of exhausting or extracting the air from the bulb, whether it be before or after sealing, is of no moment, as such methods are old; therefore open to the Westinghouse Company or any other lampmaker to use as incandescent lamps for producing light in vacuo where made and sold by De Changy, Staite, Roberts, Harrison, Lane Fox, and others long prior to Edison's application. Therefore no further comment on this point is needed.

5. The question as to time taken up in cleaning the old bulbs when in a blackened state, upon which the *Western Electrician* lays some stress: I would also say this part of the process is a very simple and easy matter to overcome, and it can be quickly and easily done by a special method by those "in the know."

Probably the most important point to consider in the new lamp is the stopper connection, but as this is tightly enclosed and embedded in a special cement within the bulb, which is afterwards covered as an additional protection, thus making it a multiple double vacuous chamber, there appears to be no reason why a good lamp of this class (if properly constructed) cannot be made to do good work and even if not quite up to the standard of a highly vacuous lamp, the new Westinghouse type can be cheaply made; besides, the first cost materials can be used over again, and as platinum is dispensed with another good point is gained. Nor does this new lamp require any expensive socket to hold it. There is also another saving. But, above all, it is a type of lamp which is absolutely free from infringement of the Edison and Swan combination claims, consequently it is certain to sell, and it is to be hoped that the Westinghouse Company will see its way clear to supply the English market with this new type of lamp; and if sold at American prices in the country, or anything under 1s. 6d. per lamp, it will then come cheaper to use, even if the life is only half as long, and for the next year or two pending the expiry of the chief lamp and holder patents, it cannot fail to find a ready market, and at the price should command a large sale. I think every reader of your journal will join with me in wishing the Westinghouse Company all the success it deserves in overcoming a difficulty by placing upon the market a lamp which is novel in construction, natty in appearance, cheap in price, and, above all, entirely free from the combination claims of certain master patents, the working of which has been unfortunately so detrimental to the real advancement of the electric lighting industry. However, as soon as lamps become cheaper, trade in plant and machinery will increase tenfold in all parts of the kingdom, as electric light in due course is certain to find a home, not only in the mansion of the rich, but also in the cottage of the poor.—Yours, etc., ARTHUR SHIPPEY.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET,

LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. IX. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

INCANDESCENT LAMP BULBS.

The blackening of incandescent lamp bulbs, and the consequent deterioration of the quantity of light, is one of the most practical questions with which electric light engineers have to contend. It is an all-important problem to the supply companies, for after the glamour of the novelty of the new lighting has worn off, users will ask to receive that which was promised them. We think it unfortunate that the unit lamp is taken as an equivalent to eight candle-power, because the sixteen candle-power lamp is the one by which comparisons by the public will be made. It is the lamp mostly to be found in the dining-room, the drawing-room, and the library that appeals to the user, not that used in bedrooms and passages. At the present moment none of us have a very distinct idea of what the unit life efficient lamp is to be. Are we in the near future to expect a sixteen candle-power lamp for a couple of shillings lasting a thousand hours, or, say, half that time—five hundred hours? We put it to all branches of the trade, manufacturers and suppliers, whether normal candle-power through five hundred hours is not enough to aim at. Probably that result, too, will be fairly achieved, though we doubt about getting the thousand hours. The user is told that such and such a lamp is a sixteen candle-power lamp, but directly he begins to use it the lamp begins to deteriorate, and in a short time, even if it commences with sixteen candle-power, it gives him less light. So, too, if the pressure is not kept constant at the point at which it is intended the lamp should be supplied. The supply being at too low a pressure was discussed in various papers not so very long ago, so that nothing more need be said on that part of the subject. The blackening of the bulb and its influence on the light has not, however, been examined in England to the extent it has in America. The most recent utterance on the subject is from Prof. Nichols, who, in the *American Journal of Science*, gives the results of the investigations of Messrs. Moore and Ling, in the laboratory at Cornell University. The results of these experiments were given in a note in our last issue, but the question is so important that we again call attention to it. In an investigation by Prof. Thomas and Messrs. Martin and Hassler, described in a paper before the American Institute of Electrical Engineers, the authors stated that if the life be limited to the time when the lamps give 75 per cent. of their initial candle-power, the average death is at 450 hours; while 80 per cent. as limit cuts them off at 340 hours, and 90 per cent. at 180 hours. These investigators also found that the lamps which were least blackened were those exhausted by mechanical pumps, hence it is inferred that exhaustion by mercury has a deleterious effect. The investigations of Messrs. Moore and Ling goes further than that of Prof. Thomas and his colleagues, and examines into causes. Thus it was found that the absorbing power of the coating is in itself sufficient to account for a very considerable falling off in the candle-power. The effect of the "age-coating," as they term the black deposit on

is to dim the lamp without appreciably he quality of the light. This means that anges and quality remains, so that if a r of candles is estimated for the lighting amount of light decreases 10 per cent. ed and eighty hours' use of the lamps. continues, and a quarter of the light idred and fifty hours. A brilliantly m in the first instance becomes nd indistinct visions; with gas ccurs—the light of the burner of the burner to-morrow here is our remedy? Not mechanical engineer (Mr. ...ne fame) showed us a plan ...n he thought the "age-coating" ...ared from the bulb easily and expedi-... We do not know if his experiments succeeded, but the idea was certainly worth a trial. There is another view of the matter, which, so far as we know, has not been considered by manufacturers; but as the controlling patents lapse and competition increases, the various problems attaching to incandescent lamps will be more closely examined. Prof. Nichols tells us that "the rate of deposit of the coating in incandescent lamp bulbs is greatest in the early part of the life of the lamp." Now, our view is that improved manufacture could alter this, or the manufacturer should not send the filament out in a bulb till the early life is passed. In other words, the particles from the filament should be disintegrated before, not after the use in a bulb. We ought even then to get a life of five hundred hours, and a rate of blackening and a diminution of light much slower than at present. Is this impossible? Mr. Shippey, in his letter in another column, says the cleaning is simple to those "in the know," but he does not explain the method, which we venture to state is not one that ought to be kept secret, but, for the benefit of all who use lamps, should be promulgated broadcast over the world.

A PACIFIC CABLE.

The *Times* of November 8 contains an evidently inspired article on the proposed Pacific cable, a proposal due to French initiation. We have our own views about a Pacific cable, which are not in accord with those of the *Times* article. In our opinion the directors of the Eastern and Eastern Extension Companies have for years done all they could to stop this cable, and have hitherto succeeded. Those two companies are to all intents and purposes one company, but it pays the wire-pullers to take separate salaries. They also would prefer a duplication of lines to Australia, not *viâ* the Pacific, but *viâ* the Indian Ocean. Unfortunately, the Australasian authorities have been divided, otherwise a cable through the Pacific would long since have been laid. By playing off one authority against the other, Messrs. Pender, Anderson, and Co. have got their will—are charging a far higher tariff than is necessary, and preventing the alternative route. Had the Australasian authorities agreed together, these gentlemen would long since have found it advisable to lay the Pacific cable under their own auspices. It needs little or no premonition to understand that all their plans are prepared for this purpose; and should the French proposals really come to anything there would be some more pretty cable fighting. Messrs. Pender and Anderson would turn faster than a weathercock, and a cable would be announced forthwith. Indeed, it would not be surprising to learn that the promulgation of these French proposals is due to the direct or indirect action of these companies. The important consideration for Englishmen is in the last sentence of the *Times* article—in fact, in the last phrase: "That the line must pass through some countries where the British Government was not supreme." Now we hold that this line should pass through countries where the British Government is supreme. Will it be believed that we have absolutely no line which our Government can control? We cannot send a message to our Asiatic colonies without the permission of a foreign Government, nor without the permission of Governments which are always more or less hostile to us. We cannot reckon upon the Governments of France, Spain, or Portugal, or upon those through whose territories the Indo-European lines pass, for neutrality or for friendship in our extremity. What we want, and what we ought to have when another international upset arises, is a means of communication wholly through English territory and under English control. This can be obtained by connecting Canada West with New Zealand or Australia, and this Pacific line should be a Government line, and under the control of no company. It should be worked at the cheapest possible rate, and if properly managed, as the Post Office Telegraph Department can manage when it has a mind to, the traffic receipts would pay a fair percentage upon the outlay. The aim of the companies all along has been to play off colony against colony, and nation against nation, to serve their own ends. There has been no patriotism, except when patriotism was intended to pay. If the shareholders reaped the full benefit of such policy, it would be a different matter; but they do not. Surely the colonies in Australasia have shown themselves patriotic enough when the welfare of the mother country was in question, and they, together with Canada and the mother country, could establish a chain of telegraphic communication under the absolute control of Britain and Greater Britain.

QUICK WORK AT HOVE.

Electrical central supply contractors are obtaining well-deserved fame in some instances for the extremely rapid work in erecting machinery and starting the supply. A recent instance of this is the central station at Hove. The New Hove Electric Lighting Company acquired, some short time back, the statutory powers under the Board of Trade provisional order granted to the Hove Commissioners in 1890, and on Saturday last supply of current was commenced to residents in about two miles of streets from a temporary central lighting station in Holland-road.

The contract for this work was placed with Messrs. Crompton and Co., Limited, exactly ninety days before the date of first supply, and the two miles of mains were laid in sixty days, an extremely smart piece of work. A large number of private consumers' houses are already wired for the electric current, and others are being wired. About one thousand three hundred lamps are connected up, thus ensuring an income of some £700 to £800 per annum from the commencement. The Hove Commissioners propose to light the Town Hall and municipal buildings with some six hundred lights, and they also intend to erect a large number of arc lamps in the streets. Messrs. Crompton and Co., Limited, are under contract for completing the laying of mains in the compulsory area by the 19th March, and they have also to erect the permanent generating and distributing station. The active manner in which both installation and distribution is being carried out promises exceedingly well for the new company, and the example will serve to have an inspiring effect on corporations still lagging in hesitation.

THE FATAL ACCIDENT AT KENSINGTON.

We should have made some remarks about this sad, and unfortunately fatal, accident at the House-to-House Company's Kensington installation last week, but pressure on our space prevented us. The facts are simple: the man T. P. Lang was handling a live wire in the ordinary course of business. The installation was probably defective, and he received a current under 2,000 volts pressure, which was instantaneously fatal. In this country the number of fatal accidents through electric light operations have, fortunately, been few, a fact which speaks well of our general workmanship. Familiarity with electrical machinery is apt to cause carelessness, and in this particular case no doubt had the indiarubber gloves been used, which at the inquest were said to be provided and ordered to be used by the company, there would have been no fatal accident. The management may make rules and provide proper appliances, but it is another matter to compel workmen to comply with such rules. In all branches of work the same difficulty arises. We have been in rooms where emery-wheels were going on every side, where the air was laden with dusty, death-dealing particles, where provision was made that every workman should wear what we might term a dust-sieve to prevent inhalation of the dust, but half the workmen are always found with no protection. Possibly it is the same in electric light matters, and the only remedy is to be exceptionally severe where negligence or breaking of rules is reported. Too great care cannot be exercised in all that concerns electric light operations, because its enemies will propagate in the widest manner tales of any indication that it is unsafe. We contend—we have always contended—that it is the safest artificial illuminant known, far and away superior in this respect, as in others, to both gas and oil.

INSTITUTION OF ELECTRICAL ENGINEERS, Nov. 24

EXPERIMENTAL RESEARCHES ON ALTERNATE-CURRENT TRANSFORMERS.

BY J. A. FLEMING, D.SC., F.R.S., MEMBER

Prof. Fleming's paper is an extremely lengthy and elaborate one, with a large number of illustrations. A considerable portion of the paper, however, is only of value to those whose hobby is "historic continuity." This enables us the better to give abstracts from the paper instead of the whole, which latter we should prefer. To make our course plain, the user of transformers, for instance, wants information about those made now, and cares little about the results obtained from those made a few years ago. The same may be said of those who use instruments: the value they want is that of the latest, not the oldest. On the other hand, the historian and the antiquarian want to know the continuous history of the machines or apparatus from the earliest to the very latest types. Prof. Fleming in this paper admirably caters for both classes but we must restrict most of our abstracts to information relating to latest types.

After introductory paragraphs, the author describes

THE METHODS OF MEASUREMENT EMPLOYED.

Mr. Swinburne placed at my disposal four of his electrostatic torsional voltmeters, and also two of his dynamometer wattmeters, and there was also at hand a sufficient supply of Kelvin [illegible] balances and electrostatic voltmeters and other appliances for the calibration of the above instruments. Since these Swinburne electrostatic voltmeters proved useful in much of the work, it may be advantageous to point out their good and bad points, and also to say how they were improved, calibrated, and used in the experiments. As they have been sufficiently described by their inventor, suffice it to say that they consist of two pairs of semi-cylindrical metal boxes B (Fig. 1), insulated from each

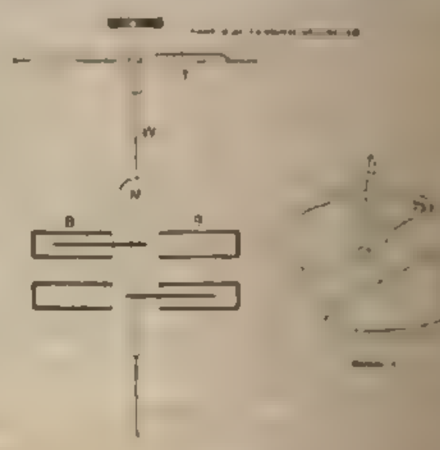

FIG. 1.

other. A vertical metallic axis carries two semicircular aluminium "needles," set at different levels, so that one is [illegible] the upper pair of boxes and the other in the lower. The [illegible] is strung at the top and bottom by a round phosphor-bronze wire 0·003in. or 0·004in. diameter, and the top end of the upper wire is held by a torsion head, T, the indicating needle of which moves over a graduated scale. In most of the experiments [illegible] voltmeters were used as idiostatic voltmeters, and the [illegible] and one pair of semi-cylinders formed one terminal of the instrument, and the other pair of semi-cylindrical boxes [illegible] terminal. When a definite potential difference is made between the two terminals, the needle is displaced from its [illegible] position, and the semicircular needles attracted into the [illegible] cylindrical enclosing boxes, which are at a different [illegible]. The upper torsion head is then turned until the needle is [illegible] back to its initial position. This is accurately [illegible] affixing a mirror to the axis of the electrometer needle. The image of the filament of an incandescent lamp is then thrown [illegible] the mirror by a lens, and, after reflection, received on a paper [illegible] about one metre away. By a simple reference point on [illegible] it is easy to bring back the line of light accurately to [illegible] position. In first working with these instruments we were [illegible] troubled by electrical discharges passing across from the [illegible] to the cylinders and destroying the suspending wire by the [illegible] ing current. The simple remedy for this was found in [illegible] each semicircular aluminium line of the "needle" [illegible] thin sheets of mica which projected slightly over the edge of the sheet of metal. The instrumental utility of the voltmeter was [illegible] at all impaired, whilst at the same time discharges between the needle and enclosing boxes were prevented, and much [illegible] thereby saved. The sensitiveness of the voltmeter was such [illegible] when used to read an alternating potential of 2,000 [illegible] a change of three or four volts was easily detected, and with [illegible] steady potential there was no difficulty in taking the readings to about this number of volts to one-quarter per cent. accuracy.

In calibrating these voltmeters, the first step was to prepare a

standard inductionless resistance capable of carrying, without sensible heating, a current of at least a quarter of an ampere, and which could be subjected to an alternating pressure of 2,000 to 3,000 volts without risk of short circuiting. This was formed by winding double silk covered platinoid wire No. 36 B.W.G. round a wooden frame. The wire windings were each kept separate by being wound in serrations, or teeth, cut in the edge of varnished slate slips fixed at the top and bottom of the frame. The frames were about 37in. long, and 14in. wide, and the wire made 56 turns round the frame, each turn of wire being separated by about a ¼in. from its neighbours. The length of wire on each frame was about 126 yards, measuring some 1,600 ohms. Six of these frames were provided, giving us, therefore, about 9,600 ohms resistance in the form of a wire perfectly insulated in every part and between every turn. This wire was capable of carrying about one quarter of an ampere without any very sensible heating, and about three quarters of an ampere without exceeding safe limits. Every part of the wire was accessible, and exposed to the cooling action of the air. The six frames were fastened up to the ceiling of the laboratory and arranged so that the direction of the wire windings was alternately right and left. The resistance of all these coils was measured when at 15deg. C., and found to be as follows:

Coil.	Ohms.
1	1,607·2
2	1,595·5
3	1,525·5
4	1,649·0
5	1,640·1
6	1,645·7
Total	9,543·0

On coil 1 two terminals were placed, one at a distance of 394·7 ohms from the end, and one at a distance of 1,212·5 ohms from the end. By taking leading wires from these points it was possible to divide the whole resistance of 9,543 ohms into two sections, having in one case resistances in the ratio of 23·175 to 1, and in the other case a ratio of 6·87 to 1. This divided resistance was a practically non-inductive resistance of about 10,000 ohms, divisible into two sections in the ratio of 23 to 1 or 7 to 1. If a measured alternating pressure of 2,400 volts was applied to the ends of this resistance, the wire came to a steady temperature of about 20deg. C. to 25deg. C. above the atmospheric temperature (15deg. C.), as nearly as could be judged by a thermometer. Taking the coefficient of change of resistance with temperature for platinoid as equal to 0·021 per cent. per degree, it will be found that at 40deg. C. the whole coil would have a resistance of 9,591 ohms, and hence, if truly non-inductive, the current through the coil would then have a value of $\frac{2400}{9591}$ ampere, = 0·250 ampere. The actual current, carefully measured by a Kelvin deciampere balance, was found to be exactly 0·250 ampere, thus showing that the resistance was, for all practical purposes, non-inductive.

In all subsequent experiments it was therefore taken that when an alternating pressure of 2,400 volts was applied to this resistance, it passed a current of 0·25 ampere and absorbed 600 watts. This resistance will be hereafter called the "No. 1" resistance for reference. By the aid of this divided resistance the Swinburne voltmeters were easily calibrated.

A 24 to 1 transformer, T_1, was connected to 100-volt mains through a rheostat so as to raise the pressure and enable it to be regulated within limits. The above standard divided resistance was placed across the high tension terminals, and a Kelvin multicellular electrostatic voltmeter and a Swinburne electrostatic voltmeter, connected respectively to the small section and to the whole length of the resistance.

By taking the readings of the Kelvin electrostatic voltmeter corresponding to various pressures and multiplying these readings by 24·175 we obtained values for the P.D. *effective* potential difference at the terminals of the Swinburne voltmeter, and hence the true values of the instrumental readings of the last named instrument. For each Swinburne voltmeter a calibration curve was then prepared, in which the *horizontal* abscissæ were the torsion head readings, and the corresponding ordinates the true P.D. in volts at the terminal of the instrument. This curve was found to be a very exact parabola.

In addition to the above standard resistance, another set of six similar coils was provided, each coil of which consisted of No. 32 B.W.G. platinoid wire wound in the same open manner on a frame. Each of these coils had a resistance of about 500 ohms, and each coil could carry comfortably, without any very sensible heating, about half an ampere. These last six coils were specially intended to be used for current measurement, as follows. The coils were arranged either two, four, or all six in parallel, and the current to be measured passed through them. The P.D. at the ends of the compound resistance was measured by a Kelvin electrostatic voltmeter. The arrangement was standardised as an ampere meter by passing known currents through the coils, measured by a Kelvin ampere balance, and then observing the P.D. at the ends of the compound resistance. In this way the true resistance of the coils grouped in various ways when carrying currents was found, and at any subsequent time the mere reading of the P.D. at the ends of the resistance gave the current passing through the coils. The reason for employing an electrostatic voltmeter and resistance in this way to measure current was that we thereby obtained an inspectional ampere meter much more convenient in many experiments than an ampere balance or dynamometer. It will be seen, therefore, that all the measurements were ultimately referred to one Kelvin electrostatic voltmeter and one Kelvin deciampere balance. These instruments were found to agree with one another. Any other instruments, such as Siemens's dynamometers or an Ayrton and Perry twisted-strip ammeter, sometimes used, were standardised and referred to the above mentioned Kelvin balance, which was one specially constructed for alternating current measurement.

This last mentioned set of six resistance coils will be hereafter spoken of as the "No. 2" set. We frequently employed the No. 1 and No. 2 resistances in series, giving us a practically non-inductive resistance of about 12,000 ohms. The No. 1 resistance was also employed as an absorber of power. For if the six coils, each of about 1,600 ohms, were arranged three in parallel and two in series, we obtained an effective resistance of about 1,100 ohms, and this, when placed across a 2,400-volt circuit, passed a total current of rather more than two amperes and absorbed about 5,000 watts. We found it very convenient to employ this resistance in this manner as a standard non-inductive power absorber for obtaining the constant of various forms of wattmeter. Although using the No. 1 resistance in this way to absorb nearly 7 h.p., the current passing in each single wire was not more than two thirds of an ampere, or well within the safe limits.

Experiments with the Three Voltmeter Method of Measuring Alternating Current Power.

Having the necessary instruments all calibrated and compared, a series of experiments was made with three or four of the Swinburne voltmeters, using them in accordance with the well known method, for measuring the power taken up in transformers on open secondary circuit.

Two 5 h.p. transformers were arranged with low-tension coils in parallel on a 100-volt circuit, and high-tension coils (2,400 volts) in series, Fig. 2. The current through the low pressure coils could be varied by a rheostat, *r*, and hence the P.D. at the high-tension terminals of the transformers given any desired value from 2,400 volts downwards.

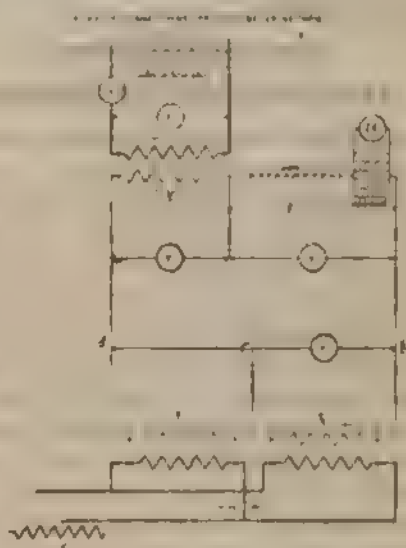

Fig. 2.

In the diagram, T is a transformer in which the power taken up is to be measured; T_1 and T_2 are the 5 h.p. pressure transformers just mentioned. The torsion voltmeters, V_1, V_2, V_3, were arranged as shown, V_1 being across the terminals of the transformer to be measured, V_2 being across a non-inductive resistance, r_1, put in series with the primary coil of the transformer T, and V_3 used to measure the total P.D. between the outside terminals of the two pressure producing transformers, T_1 and T_2. Since T_1 and T_2 were identical transformers, it was generally quite sufficient to measure the P.D. between the terminals of one transformer, T_1 or T_2, and to take double this P.D. as the value of V_3, except in cases where the total P.D. exceeded the limits of safety for one voltmeter, and then two voltmeters were used, one across the terminals of each transformer. Under these circumstances, as is well known, the power, W, taken up in the transformer, T, under test is given by the formula,

$$W = \frac{1}{2r_1}\left\{ V_3^2 - V_2^2 - V_1^2 \right\}.$$

In applying this method we had several difficulties to overcome before we could get any satisfactory results. In the first place, the transformer to be tested must have the potential difference V_1 between its primary terminals always exactly maintained at the normal pressure, which in all our experiments was 2,400 volts. In the second place, the potential difference V_2 must always be made as nearly equal to V_1 as possible, in order to obtain the condition of greatest probable accuracy of measurement; that is, to obtain the condition in which given small percentages of error in the several voltmeter readings produce the minimum percentage error in the calculated power. In the third place, the resistance r_1 must be practically non-inductive, and must be capable of being varied in amount as required to fulfil the condition of making V_2 equal to V_1. We met these conditions in the following manner: In cases in which

the transformer T was not loaded on the secondary circuit, and in which, therefore, the current flowing through its primary circuit was not greater than could be comfortably carried by the No. 1 10,000 ohm standard resistance, we employed that resistance, arranging all six coils in series. In series with this we placed some or all of the coils of the second resistance, arranged in series or in parallel, and we placed a Kelvin voltmeter to read the fall in volts down one of these last coils. In other cases, when the transformer T was loaded up on its secondary circuit, and when, therefore, a larger current was flowing through its primary circuit, we employed a series of 24 50 c.p. 100 volt incandescent lamps, or several series of lamps in parallel, adjusted as required to obtain the requisite resistance. When these lamp resistances were used, the second No. 2 set of resistance coils, arranged with two, four, or six in parallel, as necessary, were placed in series with the lamps. By measuring the fall in volts down this known wire resistance by a Kelvin electrostatic voltmeter, *Th*, and the fall in volts over the lamps and resistance taken together by means of one of the Swinburne voltmeters, V_2, we were able to determine at any instant the value in ohms of this non-inductive resistance from the readings of two electrostatic voltmeters and the known value of the wire resistance across the terminals of the Kelvin voltmeter.

The process of getting a reading was thus. The resistance r_1 was varied suitably until the value of the P.D. V_2 was as nearly as possible equal to the value of the P.D. V_3. The feeding transformers, T_1 and T_2, had a rheostat in their common low pressure circuit, which was then varied until the P.D. V_1 came to the value 2,400 volts, and it was constantly maintained at that value. The reading of the other two voltmeters was then noted, as well as that of the Kelvin voltmeter Th. If we call A the ampere value of the current flowing through the primary coil of the transformer T, and therefore also that through the resistance r, it is obvious that the value of r is determined at once from the value of the P.D. V_2 and the value of the current A. A is, of course, known by the previous calibration of the Kelvin voltmeter and associated resistance as a non-inductive ampere-meter. Hence, if V_1 is constantly maintained at the value 2,400 volts, we see that the power, W, taken up in the transformer is given by the formula,

$$W = \frac{A}{2\,V_2}\left\{ V_3{}^2 - (2{,}400)^2 - V_2{}^2 \right\}.$$

If it had been possible to make V_2 also always exactly 2,400 volts, the formula would have been still more simplified.

It will be observed that we used a row or rows of 24, or less, 50 c.p. incandescent lamps as our non-inductive resistance, and determined the actual resistance at any instant by observing the terminal P.D. of the row of lamps and the current flowing through them as measured by the fall in volts down a small known non-inductive resistance placed in series with them. We found this to be a better method than using any form of ammeter in series with the lamps: firstly, because we were more sure of not introducing perceptible inductance into the lamp circuit; and secondly, because we found we could obtain greater accuracy in the measurement of the current than by any other ammeter suitable for the purpose. The justification for using such a row of lamps as a practically non-inductive resistance is that if an incandescent lamp is placed in series with a dynamometer suitable for measuring both alternating and continuous currents, and if the terminal P.D. on the lamp is adjusted, say, to 100 volts as measured by an electrostatic voltmeter, no sensible difference can be found in the current as measured by the dynamometer, whether that current is alternating or continuous.

It will be seen that when the transformer under test is loaded on its secondary circuit, in addition to the ammeter and voltmeter measurements necessary to estimate the secondary load, we have four, and sometimes five, other voltmeter measurements to make simultaneously in order to get one observation of the power absorbed in the transformer. In dealing with the mere theory of an experimental method, nothing is easier than to say, "Let V be a constant P.D.," but in actual practice, and when working off the mains of existing public electric supply companies, this ideal condition is very difficult to realise, and the observers have their patience strained often almost up to the safe working limits to obtain any results worth having at all. We found that the multiplicity of readings to take simultaneously constituted a very great drawback to the utility of this voltmeter method. Having the apparatus, however, set up, and the instruments all calibrated, the method was applied to measure the power absorbed in a number of transformers with open secondary circuits, and in one or two cases the power taken up in the transformer corresponding to various secondary loads was also taken.

The results of some of these observations are given in the fourth column of Table I., in which the determinations of the power absorption of various transformers at no load obtained by different methods are collected. In this table the first column gives the maximum output in watts of the transformer; the second gives the "magnetising current," or primary current, at no load; the third the primary volts, or P.D. at the primary terminals; the fourth, fifth, sixth and seventh columns give various power determinations; the eighth gives the "apparent watts" absorbed at no load, or the numerical product of magnetising current and primary volts; and the ninth column gives a number which it is convenient to call the power factor of the transformer at no load—it is the ratio of the true to the apparent watts. If the currents and pressures were simple sine functions, then the power factor in that case would be the cosine of the angle of lag of primary current behind the primary terminal potential difference.

* The power determination by the three voltmeter method—viz., 126 watts—was made on one transformer, No. 1,952. The power determination by the dynamometer—viz., 140 watts—is the mean of four values obtained on another transformer, No. 1,868, the [illegible] value of which is also 126 watts.

In criticising these results, it must be borne in mind that some of the transformers were intended to be used at a frequency of 100, and not at 83, and that, therefore, comparisons between the resulting numbers are not to be instituted without regard to this circumstance. Moreover, on different days the frequency varied from 83 to 88, and this appreciably affects the power absorptions. As an example of a series of voltmeter tests, we give in Table II. the details of the observations on a series of [illegible] at no secondary load. In these tables V_1 is the voltmeter reading of the P.D. of the primary terminals of the transformer under test; V_2 is the P.D. between the ends of the non-inductive resistance, R; V_3 is the P.D. between the terminals of the pressure-supplying transformers, and W is the power in watts being taken up in the tested transformer, calculated by the formula from the three voltmeter readings. The frequency employed in each case is stated, and the value of R, the non-inductive resistance, is also given in each case. The column headed "By Swinburne Wattmeter" records the power readings taken with the first wattmeter in a brass case sent with the [illegible]-watt "Hedgehog" transformer. Quite lately another wattmeter with an ebonite outer case, was sent. This will be afterwards referred to as the "second wattmeter."

TABLE II.—Tests of Power absorbed on Open Secondary Circuit by various transformers, taken by the Three Voltmeter Method.

(1) Westinghouse transformer, 6,500 watt. R = 9,678 ohms, frequency 86·7 complete periods, magnetising current [illegible] amperes, power factor, 0·79, apparent watts taken up at no load 118. Mean of five readings = 93·5 watts.

(2) Mordey transformer, 6,000 watt. R = 12,630, frequency 82·7 complete periods, magnetising current 0·0724 ampere, power factor 0·72, apparent watts taken up at no load [illegible]. Mean of seven readings = 126 watts.

The application of the three voltmeter method to closed magnetic circuit transformers, or transformers with large power factor at no load, showed that it was possible with care to obtain very fairly good power determinations agreeing well with one another, although the number of instruments to be read rendered it exceedingly difficult, unless the pressure was absolutely steady, to get the benefit of the full possible individual accuracy of each instrument. The moment, however, that we turned attention to transformers with small power factor, such for instance as the Swinburne "Hedgehog," the difficulty of obtaining very accurate results was considerably increased. The reason for this is explained in a paper by Prof. Ayrton and Dr. Sumpner on the "Measurement of the Power given by any Electric Current to any Circuit."

Assuming currents and potentials to vary harmonically, we show that if the same percentage error, e, is made in reading each voltmeter, the percentage error in the calculated power will be

$$\sqrt{\frac{2 + 4(1 + \cos\phi)}{\cos^2\phi}}$$

times c, where $\cos\phi$ may be approximately taken to be the same quantity as that which we have above called the "power factor." Hence if $c = 1$, and $\cos\phi = 0·75$, the multiplier is found to be 5; but if $c = 1$ and $\cos\phi = 0·06$, then the multiplier is 40. In other words, a uniform error of 1 per cent. in the voltmeter reading makes only 5 per cent. error in the power when operating on a closed-circuit transformer, but a 1 per cent. voltmeter error means a 40 per cent. error in the power when testing a "Hedgehog." Hence, unless the very greatest constancy in the alternating pressure can be obtained, the three voltmeter method will not give good results when applied to an open magnetic circuit transformer. In order to show the extent of variation of the power determinations from the mean value, when applying the three voltmeter method to a "Hedgehog" transformer on open secondary circuit, the individual values obtained on different occasions were grouped showing the mean value of the power absorbed by the open circuit "Hedgehog" in these experiments to be respectively 155, 101, and 85 watts at no load. The mean of the means is 114 watts. Besides the above experiments, a number of other quite similar ones were made with the same method, which gave results as follows—viz., 111, 100, 132, 97, 118, 118, 119, 114, 98, 95, 103, and 88 watts. The mean of all the 30 determinations made with the three voltmeter method is 112 watts. This is, therefore, the mean result for the power in watts absorbed by the 3,000 watt "Hedgehog" transformer on open secondary circuit when worked at a frequency between 83 and 88. The greatest value of the watts is 171 and the least 64, and the greatest deviation from the mean is 59 watts, or, roughly, 50 per cent. The transformer was marked by the maker to be worked at 100 periods per second. We used it at 83 to 88. It appears, therefore, that, owing to the low power factor of this transformer, it is a bad subject for the three voltmeter method, and that even with the greatest precautions considerable deviations from the mean may occur in making a series of power measurements in its case. Nevertheless, it will be shown later on that there is reason to believe that the mean value so obtained of the power absorbed at no load—viz., 112 watts—is not far wrong.

As regards the three voltmeter method itself, considered as a practical method of measuring alternating current power, the following conclusions were impressed upon us: 1. It is only applicable in cases when a very steady alternating pressure can be obtained of the requisite amount, and it is therefore unsuitable in general for working as a workshop method, or off commercial alternating circuits. 2. Owing to the number of instruments to read, it is difficult to carry it out as a practically useful method without the assistance of several observers. 3. It is especially difficult, if not impossible, to get good results with it when applying it to test transformers of open magnetic circuit type, and having therefore a small power factor. 4. Unless all the conditions for maximum accuracy can be secured, owing to the nature of the formula for the calculation of the power, the results will not be very trustworthy.

In applying the method to measure the power taken up in the primary circuit of a transformer when the secondary circuit is loaded up, the non-inductive resistance R, must be capable of passing the full primary current required, and yet be capable of being so adjusted that at each stage of the load the fall of volts, V_2, down this resistance is approximately equal to the pressure, V_1, on the terminals of the primary of the transformer being tested. It is essential that this last condition shall hold good, or else we do not obtain the same probability of accuracy in the calculated value of the power given to the primary circuit at all loads. It was found, therefore, that the most convenient arrangement to employ for the non-inductive resistance was one or more parallel series of incandescent lamps. We employed one series of 24 50-c.p. 100 volt lamps and two series of 24 16 c.p. 100 volt lamps, the three series being arranged in parallel when required, and any required number out of the 24 lamps in each series taken. In order to measure the resistance at any instant of this bank of lamps, the second set of six non-inductive resistance coils was arranged in series with the lamps, and the drop in volts down this known resistance measured with the Kelvin electrostatic voltmeter. This gave us the current flowing through the lamps and the Swinburne voltmeter gave us the P.D. over lamps and resistance. Hence, knowing the terminal P.D. and the current, we have the value of the non-inductive resistance r_1 at any instant given by the inspection of two voltmeters. In making the full tests at all loads of a transformer by this method, the power given out from the transformer was taken up on a bank of incandescent lamps, and the current and terminal volts measured by a Kelvin balance and Kelvin multicellular electrostatic voltmeter. The results of a double series of observations on a Ferranti 5-h.p. 1885 (old form) transformer, and those on a Swinburne 3,000 watt "Hedgehog" are tabulated.

In these tables the first three columns give the volts, current and watts output, W_2, of the secondary circuit; the fourth column gives the primary current; the fifth the value of the inductionless resistance in series with the primary; the sixth, seventh, and eighth columns give the values of the voltmeter readings, V_1, V_2 and V_3; the column headed W_1 is the calculated value of the power given to the primary circuit; the last two columns give the value of $W_1 - W_2$, or the total power in watts absorbed in the transformer, and the ratio $\frac{W_2}{W_1}$, or the efficiency, expressed as a percentage. The values of $W_1 - W_2$ are the total power in watts dissipated in the transformer, partly as copper frictional losses (C^2R losses), partly as iron losses (eddy current and hysteresis), and in any other way, such as eddy currents in the copper circuits by which internal work is being expended.

[Tables V. and VI. relate to the old form of Ferranti transformer. Tables VII. and VIII. relate to the Swinburne Hedgehog. We give Table VII.—ED. *E.E.*]

TABLE VII.—Swinburne "Hedgehog" Transformer.

Curves representing the values of $W_1 - W_2$ for the Ferranti 5 h.p. transformer, taken from the results obtained, were shown. The secondary output of the transformer in watts is set off on the horizontal line, and the vertical ordinates of the upper curve are the corresponding values of the "total lost watts," or total power losses in the transformer at these various loads. The lower curve is the curve of total copper (C^2R) losses, taking both primary and secondary together. The difference between the ordinates of the upper and lower curves represents the power lost in the transformer in iron losses and eddy current copper losses, if any. It is seen that the upper curve keeps roughly parallel to the lower curve, and that therefore, as far as these observations go, there is no indication that the core losses get less as the output increases; on the other hand, they seem to get slightly greater. It is much more convenient and instructive to plot out in this way a "total loss curve" for the transformer than to plot an efficiency curve, for if an accompanying C^2R curve is drawn, it shows us at once what is the magnitude of the total eddy current and hysteresis losses to be accounted for. The values of $W_1 - W_2$ for the Swinburne "Hedgehog" are found when plotted to lie so irregularly that an exact determination of the total loss curve by these tables is impossible. The power factor of the "Hedgehog," even at full load, is still small, and we were not satisfied with the general nature of the results given at all loads by the three voltmeter method for this transformer. In the case of the Ferranti 5 h.p. transformer (1885 type) the determinations of the power taken up at no secondary load were fairly consistent, being as follows for seven observations: 516, 515, 504, 540, 538, 509, 516, all taken at a primary pressure of 2,400 volts and a frequency of 82 to 85. The mean of these values is 520 watts. At a frequency of 87 and a primary voltage rather above 2,400, we found for the same quantity the values 563, 565, 568, 552, 568, 561 watts, in six different experiments. The mean of all, corresponding to a frequency of about 83, is probably close to 540 watts.

EXPERIMENTS WITH THE THREE AMMETER METHOD OF MEASURING ALTERNATING CURRENT POWER.

We next directed our attention to that modification of the voltmeter method suggested by the writer, and which involves current measurements instead of pressure. Theoretically, this method requires three ammeters, A_1, A_2, A_3, arranged in connection with the transformer under test, as shown in Fig. 3. The third ammeter, A_3, measures the current flowing through an inductionless resistance put across between a pair of high tension mains kept at the potential required for the primary circuit of the transformer to be tested. Two other ammeters, A_1 and A_2, measure the current before and behind the point of take-off of this resistance. In putting this method into practice, we found it necessary in the first place to scheme some simple method of regulating the P.D. at the terminals of the transformer under test. This was accomplished as follows. A 10-h.p. transformer had its primary, or fine wire, circuit inserted in series with the primary current of the transformer under test. The secondary, or thick wire, circuit of the 10-h.p. transformer was closed through a variable resistance consisting of 15 to 20 plates of battery carbon 3in. square and ¼in. in thickness, pressed together more or less by a screw clamp. By suitably compressing these plates we were able to regulate with great nicety the secondary current of the 10-h.p. transformer, and hence to adjust the resultant impedance of the primary circuit of the 10-h.p. transformer. The volts at

the terminals of the transformer under test could then be kept perfectly constant, irrespective of slight variations due to the dynamo. This adjustment was made by placing one of the Cardew or Swinburne voltmeters across the terminals of the transformer under test, and always adjusting the carbon rheostat until the P.D. of these terminals was 2,400 volts. As a non-inductive resistance we employed a series of 50 c.p. incandescent lamps. We then found that, working under these conditions, we could dispense with the third ammeter, A_3, and make one measurement once for all of the current taken by this series of lamps at 2,400 volts. We found that this current remained constant over great ranges of time. The experiments consisted, therefore, in measuring the primary current of the transformer under test by two ammeters in series, from the junction point of which was led off the constant current for a series of lamps. The P.D. at the ends of this series of lamps was kept perfectly constant at 2,400 volts, as shown by the voltmeter, V. We found considerable difficulty in getting two suitable ammeters for the positions A_1 and A_2 which would agree with one another with the requisite accuracy, and finally we reduced the method to the use of a single ammeter as follows. An ammeter was put in the primary circuit of the transformer under test, and the P.D. at the terminals of this transformer was kept constant at 2,400 volts. A series of incandescent lamps, generally 24 100-volt 16 c.p. lamps, was joined across the primary mains, and two readings of the ammeter taken—a first when the row of lamps was between the ammeter and transformer, and a second when the ammeter was between the lamps and transformer. An independent determination was made of the current taken by the lamps. These changes of position of the ammeter were made by mercury cup connections, so as to avoid at any time actually breaking the primary circuit. As an ammeter we employed first an Ayrton and Perry twisted strip ammeter and finally a Siemens dynamometer of low resistance. It will be easily seen that this single ammeter method possesses all the advantages, whatever they are, of the three ammeter method, and is much simpler to work.

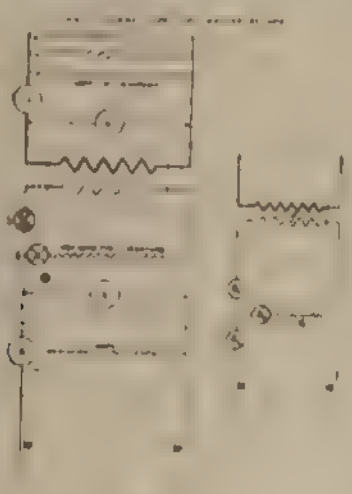

FIG. 3.

If A_1 is the reading of the ammeter when it is between the transformer and the lamps and A_2 the reading when the lamps are between it and the transformer, and A_3 is the value of the current through the lamps, and V the P.D. at the terminals of the series of lamps, it is easy to show that the power, W, taken up in the transformer is given by the expression,

$$W = \frac{V}{2 A_3} \left\{ A_2^2 - A_1^2 - A_3^2 \right\}.$$

In order to test the method, we applied it to measure the power taken up in the practically inductionless resistance coil No. 1 standard. The resistance of this coil when traversed by about a quarter of an ampere is 9,590 ohms. The value of the currents were in this case $A_2 = 0.88$, $A_1 = 0.24$, $A_3 = 0.65$, and $V = 2,400$.

Hence the power taken up, as calculated from the three ammeter observations, is 544 watts; whilst the power absorbed, as reckoned from the known value of the resistance and current going through it, is 552 watts. Applying it to measure the power absorbed in two transformers already tested by the voltmeter method, viz., the 5 h.p. Ferranti and the 6,500-watt Westinghouse—when on open secondary circuit the number obtained by the ammeter method was 590 watts for the Ferranti and 95 watts for the Westinghouse. These values are rather higher than the mean values obtained by the voltmeter method, viz., 540 and 93.5 watts; and, in spite of its greater simplicity, the one ammeter method did not give very satisfactory results, even on closed magnetic circuit transformers. It was next applied to test the Swinburne 3,000 watt "Hedgehog" when on open circuit. It was found here that, as in the case of the three voltmeter method, still greater difficulty was experienced in getting experimental results which agreed numerically well together.

It is not worth while to give all the details of the observations made on the 3,000 watt "Hedgehog" transformer by this one ammeter method. Suffice it to say that, using sometimes an Ayrton and Perry twisted strip ammeter carefully calibrated, and sometimes a Siemens dynamometer, both adapted for measuring from 0.02 to 4 amperes, we obtained such figures as these for the power in watts taken up at no load in the transformer, viz., 116, 116, 183, 154, 100, 164, 176, 119, 124, 200, 113, 71, 79, 79, 67, 108, 87, 76, 103, 88, 100, 80, 88, in 23 different determinations. Curious to say, the arithmetic mean of all these values is [illegible] or almost exactly the same as the mean value obtained from the 20 observations by the three voltmeter method, that the greatest [illegible] from the mean being about the same percentage. The conclusion arrived at with respect to this ammeter method is, that ordinary commercial ammeters do not enable us to determine the currents with anything like the accuracy necessary, when we are operating on open magnetic circuit transformers at no load. It would certainly be necessary to be able to read currents of magnitudes from 0.25 to 5 amperes to the third decimal place, and that is not in general a practicable matter by commercial instruments. After many further trials of this method on different transformers, we were obliged to come to the same conclusions with respect to it as those forced upon us in regard to the voltmeter methods, viz., that it is an unsuitable one for transformers of small power factor, but that with great care and a suitable ammeter it may be made to yield fairly good results on closed magnetic circuit transformers of large power factor. It may be noted in passing that in applying this ammeter method in any case the most favourable condition for accuracy is when the current through the transformer primary is equal to the current through the non-inductive shunt. Hence the shunt [illegible] should be decreased as the load on the secondary of the transformer is increased if we desire to obtain maximum possibility of accuracy in the measurements of the power supplied.

EXPERIMENTS WITH THE DYNAMOMETER WATTMETER METHOD OF MEASURING ALTERNATING CURRENT POWER.

Dissatisfied on the whole with the practical results and difficulties of the voltmeter and ammeter methods, attention was next turned to the employment of the dynamometer wattmeter as an instrument for the measurement of the power given to the primary circuit of transformers. There is no need to recapitulate well known facts about the use of such an instrument for this purpose. It is well understood that a wattmeter or dynamometer with independent series and shunt coils can be used for this purpose provided that the shunt circuit has a practically zero time constant, and the only difficulty which presents itself in passing an opinion on the suitability of any particular form of dynamometer for this purpose is that of knowing whether the shunt circuit really is practically so far free from self-induction or capacity as to make this the case; and this, as our experiments show, must not be taken for granted without investigation. Two wattmeter dynamometers were [illegible]. The first consisted of a Siemens dynamometer of the [illegible] pattern intended to be used as an ammeter for currents from [illegible] to 4 amperes. The fixed coil consisted of a few dozen or so turns of wire, and the movable coil of four turns. We arranged the connections so that it could be used as a wattmeter, the fixed coil being the series coil, and the movable coil of four turns being put in series with 24 100-volt 16 c.p. incandescent lamps, or with two rows of 24 16 c.p. lamps arranged in parallel, and so arranged as a shunt circuit. Contrary to the usual practice we had then a wattmeter in which the shunt circuit carried the larger current. This circuit was traversed by a current of from 1.8 to 2.4 amperes when placed across 2,400 volt mains, according to the group of lamps used.

This dynamometer wattmeter had then a shunt circuit consisting of the 24 series of lamp filaments plus the four turns of wire on the movable coil. It had, therefore, a very small inductance. This wattmeter was calibrated by applying it to measure the known power taken up in our standard resistance. The six coils of our No. 1 resistance, each consisting of about 1,000 ohms, were arranged, two in series and three in parallel, across 2,400-volt mains. The current through these resistances was measured by a Kelvin decimal zero balance, and found to be 2.230 amperes; the P.D. between the mains was measured by a Swinburne voltmeter and found to be 2,400 volts and kept at that value by a regulating transformer with carbon resistances in the secondary circuit, see Fig. 4; and from these measurements the power taken up in the resistance was known. It was [illegible] watts. The dynamometer wattmeter was then arranged so as to measure the known power being absorbed by this resistance, and the constant of the wattmeter thus determined. A torsion of 175deg. of the dynamometer head was found to be required when the resistance was absorbing the above power. This constant was frequently determined. The value was close to 30.4 watts per division of the scale. It will be seen, therefore, that we were employing a wattmeter which, although it absorbed considerable power in its own shunt circuit, had a range of measurement from 12,000 watts down to about 10 or 12 as a minimum reading.

(To be continued.)

The discussion on Prof. Fleming's paper was adjourned to next meeting.

Student.—Fredric Joseph Warden-Stevens, Manor Lodge, Brockley, S.E.

REVIEWS.

Popular Electric Lighting By Captain E. IRONSIDE BAX. Second edition. Illustrated. Biggs and Co.

This attempt to induct the householding public into the mysteries of electric light by sensible and straightforward description and instructions has won the favour of those for whom it was intended, as the appearance of the second edition proves. The new edition is rearranged, and in part rewritten. The technical glossary is relegated to the end and the map of the Westminster district is omitted, making the book more general, and therefore more acceptable to the other supply companies. The advantages of the use of electricity are duly insisted upon, and some very necessary cautions are given against too cheap contracts for wiring. When, however, every person naturally wishes matters to be arranged economically, it is difficult for the householder to judge whether the estimate is too low unless several are obtained. The book therefore gives some specimen estimates. When settling on the position of lamps, Captain Bax suggests the use of a double kerosene lamp to be moved about till good lighting effect is obtained. A useful hint is on the arrangement of switches; careful consideration of their position beforehand will often obviate an otherwise excessive bill, for where the switches turn on several lamps in groups the expense of current will certainly be many times more than really necessary. The diagrams of fuses are plain and easily comprehensible, and the fittings chosen for illustration, though fewer than, perhaps, intending customers would desire, are elegant. The expense of the light is, however, the chief point, and considerable attention is therefore given to the meter question. Estimates, glossary, and list of companies brought up to date, complete this little volume, which is certainly one of the best and most practical of the popular books on house electric lighting.

MOMENTUM AND *VIS VIVA*.

SIR,—In the penultimate paragraph of p. 519, the statement is made that "Momentum signifies the stored up or kinetic energy possessed by a body by reason of its velocity."

This is inaccurate, for *momentum* or quantity of motion (an important value in dynamics), is expressed by $m\ v.$, whereas kinetic energy varies as $m.\ v^2$, or *vis viva*.

I should be sorry to see Mr. Guy's useful work in any degree marred by a *lapsus* which some physicists at least might consider of importance.—Yours, etc.

DESMOND G. FITZGERALD.

CHEAPNESS AND EFFICIENCY.

SIR,—I just notice in your issue of the 18th a remark, in the matter of storage batteries, that "the Electrical Power Storage Company from a business point of view would seem to favour cheapness rather than extreme efficiency."

This class of remark being easily made, although not so easily substantiated, is becoming just a little too common. The Electrical Power Storage Company is quite prepared to supply accumulators taken at random out of its stock at any time, and to have these accumulators tested by independent parties against any type of manufacture at present existing, both for efficiency and durability; and I take it that this is the best answer that the company can make to such questionable means of advertising so-called new inventions by unfair comparison with the company's goods.

Yours, etc., FRANK KING, Manager,
Electrical Power Storage Company, Limited.

London, November 20, 1892.

Louvre Lightning Conductors.—According to the *Petit Journal*, out of 25 lightning conductors which are fixed on the Louvre, there is not a single one in good order. All the rods are broken, or rusty, and are so many danger points instead of safeguards.

WIRE-TO-WIRE ELECTRIC COMMUNICATION.

Some very interesting and important experiments, which have been conducted near Cardiff, under the direction of Mr. W. H. Preece, F.R.S., chief engineer and electrician to the Post Office, have already afforded results which seem to promise the realisation, at no distant time, of the hope, long cherished by electricians, that they may ultimately succeed in transmitting signals to distant points without the employment of intervening wires or other conductors. The methods by which it has been proposed to accomplish this end have been various; but that employed by Mr. Preece has depended upon the utilisation of the induced current, which was first discovered by Faraday, and which is now well known to be excited in a wire by the passage of an ordinary generated current along another wire standing in certain relations to the former. All who are in the habit of using the telephone must have been frequently conscious of the presence of a disturbing element, which usually manifests itself by the production of a sound variously described as resembling frizzling or frying, or as being like the pattering of hail against a window pane, but which sometimes interpolates distinct speech, not belonging to the message which is being designedly transmitted. This possibility of overhearing in one telephone circuit a conversation which is being carried on in another, lowers the value and destroys the privacy of the telephone as a means of communication. The fault depends upon the use of one wire and the earth, instead of two wires, to form the electric circuit. A metallic loop of two wires, abandoning the use of the earth, removes the cause of the indicated disturbances, which are due to the influence which a single wire, carrying an electric current, exerts by induction upon other wires in its immediate neighbourhood. An alternating current in one wire is reproduced by induction in another similar neighbouring wire, but in a diminished degree, the diminution appearing to depend principally upon the distance which separates the two. The extreme delicacy of the telephone has rendered such disturbances audible at very considerable distances. Signals sent through telegraph circuits underground, below the London foot pavements, have been read on telephone circuits above the housetops 80ft. away. Mr. Preece brought the first observed instance of this kind before the British Association, and in subsequent papers he was able to trace similar disturbances to currents which were being transmitted at distances of more than a mile. In a paper read before the association at the Manchester meeting in 1887, Mr. Preece stated that "the distance through which communication can be maintained between ship and ship, between lightship and shore, between islands and the mainland, between the defenders inside and those outside a beleaguered city, becomes simply a question of calculation." Researches with a view to the practical transmission of electricity through space were soon afterwards undertaken in the United States by Mr. Edison; and, especially on account of the great importance of discovering an easy method of communicating between the shore and lightships, Mr. Preece lately obtained the sanction of the Postmaster-General and of the Treasury to the series of experiments upon which he is still engaged. He proposed to conduct them in three different methods—first, by running a wire along the shore on light poles for a distance of about a mile, and a second wire from stem to stern of the ship, the two acting upon each other inductively through the intervening space; secondly, by suspending a short line over the side of the ship, so that it may dip into the sea in the direction of the end of the shore line, to work by conduction through the sea; and, thirdly, by running out a light cable from the shore to the ship, terminating in a coil at the bottom of the sea, near the ship, but not attached to it, while another coil is placed on board. These two coils are expected to act inductively, and to give ample sound on telephones by means of rapid alternations.

The experiments by the first method have been carried to a successful issue within the last few days, the shore wire having been erected along the Welsh coast, commencing at Lavernock Point, a little south of Cardiff, and proceeding for a mile in the direction of Lavernock House. The lightship was represented for the occasion by the island of Flat Holme, in the Bristol Channel; and the line there erected, parallel to the first and three miles distant from it, was about half a mile long. The shore line was furnished with a powerful generator at Lavernock Point, and the island line with a sounder to receive the messages. The result was that the words despatched into the mainland wire were heard on the island with perfect distinctness, and that a communication was thus established between these two points, distant three miles from each other, of a kind which would be absolutely independent of light or darkness, of wind or storm, of fog or rain. The principle underlying this method of communication is precisely analogous to that which governs the transmission of light itself, and by which the illumination of a lighthouse or of a lightship is rendered visible. The researches of modern physicists have led them to the conclusion that, as light is an effect produced by a succession of exceedingly small waves in the generally

pervading ether, so electricity is an effect of the succession of larger waves in the same ether, and that there is probably no other difference between the two than that of magnitude of undulation. We are familiar with a similar difference, but of much smaller degree, between the undulations of light, of heat, and of chemical activity. The solar rays contain all these forms of force, and, if we pass them through a prism, they are all bent or refracted from their original direction to an extent governed by the respective magnitudes of the undulations. Waves which range in magnitude from about 37,000 to about 65,000 to an inch are visible to the eye, and are recognised, the largest as red light and the smallest as violet light, while an intermediate magnitude produces the sensation of green. Waves of greater magnitude than the red, which are invisible, may easily be shown to be sources of heat, while waves smaller than those of the violet, and also invisible, may be shown to be sources of chemical change, and to be the active agents in photography or in bleaching by sunlight. The waves of electricity differ from those of light in being of vastly greater magnitude, so that they recur in hundreds in a second instead of in billions, and also in having a much greater range of magnitude, extending from those just outside the limit of visibility to some of hundreds of feet, or even much more in length. These long waves, moreover, will penetrate many media which are impervious to smaller ones, and the researches of Prof. Tesla have shown how much the penetrating power of electric waves may be increased by rapidity of alternation. Vulcanite, for example, is the best known insulator for the electricity of the ordinary dynamo, or of the ordinary induction coil, either giving a current of about 80 alternations a second; but the Tesla currents, which may reach a million or a million and a half of alternations in a second, will pass through it as if it were not there. The character and the rate of alternation of an electric current will probably be found to exert a considerable influence upon its power of inducing similar currents in distant wires, and one impediment to the application of Mr. Preece's recent work may perhaps arise from the difficulty of generating the currents best suited for the purpose in lightships and other places where they may be required.

Considerable attention was attracted last February by an article on the future of electricity, from the pen of Prof. Crookes, which appeared in the *Fortnightly Review*, and in which the learned author referred to the "bewildering possibility" of telegraphy without wires, posts, cables, or any of our present costly appliances. The suggestions contained in that article proceeded upon lines totally different from that of the utilisation of induced currents, and were based upon the idea that the waves of electricity might be generated of known magnitudes, and then reflected or refracted, like those of light, through or from suitable media, and so directed as to meet in a focus upon a receiving instrument, adjusted to respond to vibrations of such definite magnitude and to no others. Excepting for some chamber experiments to which Prof. Crookes referred, this ground appears to be still untrodden, except that Mr. Edison has suggested the use of captive balloons as intermediate stations, by which a message might be forwarded through space from one to another in such a manner as to overcome the difficulties in the way of direct transmission which would be due to the curvature of the earth's surface. Mr. Edison merely proposed, for this purpose, to use the waves which would radiate from each station in every direction, and not at all to refract or to guide them. Prof. Crookes attached much importance to the generation of waves of definite length, pointing out that a receiver might be constructed that would be dumb to all others, just as the human eye is blind to undulations larger or smaller than those already specified, and he was of opinion that the infinite number of possible wave magnitudes would render it almost hopeless for any unauthorised person—an enemy in time of war, for example—to seek to intercept a message which he was not intended to receive. No one but the sender and the receiver need know the wave length to which the instruments were adjusted, and, without this knowledge, experimental trials might be indefinitely prolonged without success. Even in the method which Mr. Preece is now engaged in developing, it seems not improbable that definiteness of wave length may prove to be an element of great value for the purpose of obtaining the most efficient induction, as well as for the preservation of secrecy. Although generated in a finer medium, there is no reason to doubt that the waves of ether are governed by the same laws as those of air, with which we are familiar as the producers of sound, and it is well known that given sound waves will only excite vibration in a string which is properly attuned to them. It will almost certainly be found that the same principle will apply to the induction of electrical currents, and that precise conditions will be ascertained under which such induction will, on the one hand, attain its maximum, or, on the other, be restrained from occurring. The material through which the primary current is transmitted, the material and the physical condition of the secondary wire or other conductor, and the magnitude and the rapidity of alternation of the electric waves, will all in high probability be important factors in the production of the result. Until all questions of this nature have been completely elucidated, it would be rash to place any limit to the [illegible] to come to the Cardiff trials. The closing months of the year have witnessed easy communication with a receiving instrument three miles distant from the operator, and connected with him only by the ether which occupies interstellar space. It is possible, and not unlikely, that this first achievement may soon be as far surpassed in magnitude and in importance, as the first induced currents exhibited at the Royal Institution by Faraday have been surpassed by the machinery and the applications of the present day.—*The Times, November* 22.

COMPANIES' MEETINGS.

HOVE ELECTRIC LIGHTING COMPANY.

The first meeting of the shareholders of this Company was held on Monday, at the offices, Mansion House-buildings, Great [illegible] Folgate, E.C., in the chair.

In moving the adoption of the report and accounts, the **Chairman** said that Messrs. Crompton and Co., Limited, had very satisfactorily carried out the first portion of their contract with the Company that the temporary station was practically complete. Two miles of mains had been laid, and everything done to the satisfaction of the Hove Commissioners. The actual supply of current was commenced on Saturday. From the number of applications received from customers and other indications, the Directors felt that the future success of the Company was practically assured. Up to the present time applications had been made for [illegible] lamps, and negotiations were in progress for the lighting of the Town Hall and the streets at Hove.

Mr. Albright proposed a vote of thanks to the Chairman, which was seconded by **Mr. Sutton**, and carried.

COMPANIES' REPORTS.

SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

Directors: J. S. Forbes, Esq. (chairman); W. Cuthbert Quilter, Esq., M.P. (deputy chairman); E. W. Batt, Esq.; Major S. [illegible] Page, J. W. Swan, Esq.

Tenth annual report of the Directors, together with a statement of accounts for the year ending 30th September, 1892, presented at the ordinary general meeting of the Company, [illegible] at the Cannon-street Hotel, London, on Tuesday, 29th November, 1892, at 12 noon.

The profit and loss account for the year shows a credit balance of £34,840 11s. 11d., which, together with £8,010 [illegible] brought forward from the last account, makes the [illegible] £42,850 [illegible] 0d. An interim dividend in respect to the first half of the year, amounting to £14,558 [illegible] 8d., has already been paid. The Board propose that a further sum of £21,0[illegible] be divided free of income tax, and that £6,821 17s. 9d. be carried forward. The distribution of this amount in accordance with clause 77 of the articles of association will work out at [illegible] per share on the 78,949 ordinary shares of the Company, £5 [illegible] and at [illegible] per share on the 10,750 £5 fully paid, being equivalent to 10 per cent. per annum on the partly paid and [illegible] that rate upon the fully paid shares. The dividend will be paid upon the register as it stood upon the 15th November, and the warrants will be issued on the 15th December. The [illegible] of the German patents of the Company having happily terminated, and the bulk of the capital of the Company being now [illegible] the Edison and Swan Companies in Great Britain and [illegible], the Board believe that the time has arrived when a [illegible] of the realisation of the foreign business of the Swan Company with the British Edison and Swan Company may be effected with advantage to both interests, and negotiations are pending with a view to effecting some arrangement in this direction. The Directors desire to record their sense of the loss which the Company have sustained by the death of Mr. F. R. Leyland, late chairman of the Company. The Directors have elected Major Samuel Flood Page, who had been secretary and manager of the Company for several years, to a seat on the Board. The Directors who retire by rotation are Mr. J. S. Forbes and Mr. E. W. Batt, who, being eligible, will offer themselves for re-election. Messrs. Welton, Jones, and Co., the auditors, will also retire, and will offer themselves for re-election.

Profit and Loss Account, Year ending Sept. 30, 1892.

NEW COMPANIES REGISTERED.

Electrical Wonder Company, Limited.—Registered by Beyfus and Beyfus, 69, Lincoln's-inn-fields W.C., with a capital of £10,000 in 9,900 ordinary and 100 founders' shares of £1 each respectively, the founders' shares to receive one half of the net profits of the Company after payment of 10 per cent. dividend on the ordinary shares. Object: to adopt and carry into effect an agreement, made November 4, between E. Cohen of the one part, and H. Felgate, on behalf of this Company, of the other part, for the acquisition of all the rights of the said E. Cohen with respect to the electric Schnelsehr automatic apparatus; generally to carry on business as proprietors of automatic and other machines, and to develop and turn to account the same in such manner as the Company may deem expedient. There shall not be less than three nor more than five directors. The first are A. Schwartz, T. E. Pollen, Count Max Hollender, and E. Cohen. Qualification, 250 shares. Remuneration, £500 per annum, divisible according to attendance at Board meetings, the chairman receiving double fees; when there are more than four directors, an additional £100 per annum for each additional director.

BUSINESS NOTES.

Oxford.—The Electrical Committee of the Oxford Town Council has been discontinued.

Catalogue.—We have received a catalogue of dynamos from Messrs. Statter and Co.

Western and Brazilian Telegraph Company.—The receipts for the week ended November 18 were £2,905.

West India and Panama Telegraph Company.—The receipts for the half-month ended November 15 were £2,139, against £2,314.

Fire Station.—A new fire station, with all the newest appliances, is under course of erection at Dulwich by the London County Council.

Swansea.—At the Swansea County Council a letter was received from Mr. J. C. Howell, Llanelly, applying for permission to lay an electric main from the Alexandra Arcade to the premises of Mr. W. Edwards, draper, Oxford-street.

New Chairman.—Mr. George Herring has been elected chairman of the Electric and General Investment Company, Limited, in succession to the late Duke of Marlborough.

Torquay.—The Torquay Electricity Committee consists of Messrs. R. Crocker, Lorimer, Kerswill, Richardson, Harrison, Smerdon, and the new members for Waldon and Strand.

Newington.—The General Purposes and Lighting Committee of the Newington Vestry recommended at the last meeting that the Vestry should be empowered to supply electric light in the parish, and it was resolved that this step should be taken.

Spanish Submarine.—The numbers are announced of 89 bonds, amounting to £8,900, of the Spanish National Submarine Telegraph Company, Limited, 6 per cent. mortgage debentures drawn for payment at par on December 31 next at the offices, 106, Cannon-street.

City and South London Railway Company.—The receipts for the week ending November 20 were £899, against £792 for the corresponding period of last year, or an increase of £107. The total receipts for 1892 show an increase of £1,640 over those for the corresponding period of 1891.

Greenock Exhibition.—A Marine Industrial and Educational Exhibition opened yesterday at Greenock is lighted throughout with electricity, the installation comprising 20 arc lamps, besides a large number of incandescents, and over 20 miles of wire has been used in wiring the exhibition.

Barnet.—At the Barnet Local Board meeting it was reported that the draft memorial to the Board of Trade had been presented. A letter from Messrs. Ingledew, Ince, and Colt, solicitors to Mr. H. F. Joel, with reference to the provisional order in the matter of the electric light, was considered in committee.

Arlecdon.—At the Arlecdon and Frizenball Local Board, the question of water power and electric light was again raised. Mr. Boyd found the pressure in the town insufficient to use. Mr. Richards suggested Ehen Beck. Mr. Toye thought they should wait and see how Whitehaven got on, and the question was eventually held over.

Holborn Installations.—We understand that Messrs. Vaughan and Brown, of 16 and 17, Kirby-street and Farringdon-road, E.C., have installed the electric light at Sexton's Repository, Central Hall, Holborn, with 600 lamps; the Palace Theatre with about 1,000 extra lamps; also The Blue Posts Hotel, Tottenham Court-road, and The Flying Horse, Oxford-street.

Wycombe.—The Wycombe Corporation have decided not to proceed this session with the application for a provisional order to supply electricity. This conclusion was come to at the meeting held *in camera* for the selection of the mayor. The cost of the order was estimated at over £200, and hesitation was evinced in authorising the spending of this sum at the present juncture.

Electric and General Investment.—The Directors have declared an interim dividend at the rate of 20 per cent. per annum for the six months ending November 30, 1892, on the capital paid up on the ordinary shares of the Company, the same to be payable on and after December 15 next, and it is notified that the transfer books of this company will be closed from December 1 to 15 inclusive.

City of London Electric Lighting Company, Limited.—This Company furnish particulars of the present position of their capital. The authorised share capital is £400,000 in £10 ordinary shares, and £400,000 in £10 6 per cent. cumulative preference shares. Of these there have been issued £400,000 ordinary shares (fully paid), £200,000 preference shares (£4 paid, next call of £9 due January 16, 1893).

Northampton.—At the meeting of the Northampton Town Council last week the Highway, Lighting, and Building Committee stated that they had inspected the electric light on the Market-square fountain, and Mr. Beale, engineer to the Northampton Electric Light and Power Company, had been asked to send to the committee the cost of lighting the square. The report was adopted.

Consulting Engineer.—Mr. Edwin Blakey has lately severed his connection with Messrs. Blakey, Emmott, and Co., Limited, with whom he has been identified for many years, and is now practising as a consulting engineer and electrician at 27, Taufield-chambers, Hustlergate, Bradford. His long experience in electrical matters will enable him to undertake important work, and we wish Mr. Blakey every success in his new departure.

Dundee.—The first meeting of the Dundee Gas Commission, as now constituted, was held last week. The engineer submitted a report which bore that up to date current had been applied for for 870 lamps of 16 c.p., or their equivalent, and that the engineer had been informed of 300 more. This is in addition to arc lights, of which about 16 are applied for. It was agreed to fix the meter rents on a scale of 12½ per cent. on the cost of the meters.

Siam.—The Brush Electrical Engineering Company, Limited, have received advices by cable from their representatives at Bangkok that the central station plant supplied by them to the Siam Electric Light Company has undergone the fortnight's trial prescribed by the arbitrators under their award, with complete success and to the entire satisfaction of the experts, and that the balance of moneys due thereon has been paid over by the Treasury.

Worcester.—At the meeting of the Worcester Watch Committee last Friday, it was resolved to recommend the City Council to purchase Powick Mills, on the River Teme, for the purpose of electric lighting, at a cost of £5,000, and to accept an alternative tender by the Brush Company amounting to £23,209. It was

stated that by utilising the water power of the Teme for generating the electricity a saving of £1,116 per annum would be made.

Blackpool Electric Tramway.—The Blackpool Corporation have decided to extend the electric tramway which has been such a prominent feature of their promenade. It is intended to carry the line round Whitegate-lane, Marton, from thence along Common-lane to South Shore, where it will join the existing line. A new company is in process of formation to construct a similar system of tramways between South Shore, St. Anne's, and Lytham.

Incandescent Electric Lamps.—The Edison and Swan Company are advertising with reference to the statement made in the circulars of foreign lamp makers which are now being circulated in this country, to the effect that the company's lamp patents are now at an end, that such statement is incorrect, and they give notice that legal proceedings will be taken against all users of lamps other than those manufactured by the company and marked with their name.

Glasgow.—The work of completing the installation for the lighting of the streets in the central districts of Glasgow by electricity is being rapidly pushed forward, and already the iron conduits in which the wires are placed have been laid underneath the foot pavements in many of the principal thoroughfares. The lamp pillars for the new light will stand over 21ft. high, and as a first instalment 106 of these lamps are to be fitted up. The pillars will be placed at the kerb of the foot pavement.

Launch of a Telegraph Steamer.—On Saturday there was launched from the yard of Messrs. Ramage and Ferguson, Limited, a steamer built to the order of the Western and Brazilian Telegraph Company, Limited, London. The principal dimensions are 220ft. by 31ft. by 23ft. 3in. mld. depth, with triple expansion engines. The vessel will be completely equipped with all the most modern appliances for cable laying and lifting purposes. On leaving the ways the steamer was named the "Norseman" by Mrs. Ramage, The Hawthorns, Bonnington.

Clapham-Paddington Electric Railway.—In the ensuing session of Parliament a Bill is to be introduced with the object of seeking powers for the construction of an underground electric railway commencing at a point in close proximity to Clapham Junction, and passing thence via South Kensington to a point near the Great Western Railway Company's terminus at Paddington. The proposed railway appears to be an extension in the direction of Clapham Junction of the South Kensington and Paddington Subway scheme, which was promoted in 1891, but withdrawn before it was considered by a Select Committee.

Overhead Wires at Guildford.—At the meeting of the Guildford Urban Sanitary Association last week, a correspondence which had passed between the London and South Western Railway Company and the Board of Trade, with reference to the proposed by-laws relating to overhead wires, was read by the clerk. The company requested that they might be heard on the subject before the by-laws were confirmed. The Board of Trade asked to be furnished with the Authority's observations on the matter. On the motion of Mr. F. Wheeler, seconded by Mr. E. H. Hitchcock, the question was referred to the Paving and Lighting Committee.

City Lighting.—A letter was received at the meeting of the Commissioners on Tuesday from the City of London Electric Lighting Company relative to the progress made in lighting the City by electricity. They stated that out of 515 arc lamps contracted for in the principal streets, 409 had been supplied, some of them three months before the contract time. Of the remainder, the positions of 44 had not yet been definitely fixed, but the rest would be completed as soon as the operations retarding them, for which they were not responsible, such as the repaving of streets, were finished. They were now prepared to go on with the erection of the incandescent lamps in the smaller streets.

Windsor.—Mr. Thomas Dyson, writing to the *Windsor Gazette*, admits that to raise the head of water from the river would be most detrimental to the water service of the town, but to utilise the "tails" of our streams, now running to waste, which he hopes will be done some day, with any water power they may have to spare, would be a stroke of wisdom and a profitable transaction. The generating of electricity by water power at the water works dates to my knowledge as far back as 1884, and he thinks that if Mr. Cutler had continued to be the proprietor of the water works, something would have been done ere this, to use the valuable element—"Heaven's free gift"—that lies at their feet night and day.

Town and County Installations.—Among the important contracts lately obtained by Messrs. Drake and Gorham, in London, we observe the lighting of the residence of the Right Hon. Baron Henry de Worms, M.P., at 42, Grosvenor-place; the London residence of Sir E. H. Carbutt, Bart., at 19, Hyde Park-gardens; also 54, Lowndes-square, for Mr. Nicholas Wood; 6, Moorgate-street, for Messrs. Schwann Bros.; and they have just completed 65, Old Bailey, for Messrs. John Dickinson and Co. We also understand that they have in hand several country house installations, amongst which we may mention those for Sir Gervase Glyn, at Ewell, Surrey; J. Hallett, Esq., at Orpington, Kent; and R. Hermann, Esq., at Cambridge.

Newington.—At the meeting of the Newington Vestry last week Mr. Cole moved the following recommendation of the General Purposes and Lighting Committee: "That having regard to the financial success attending the electric lighting in the parish of St. Pancras, this Vestry is of opinion that if a competing supply is considered expedient in this parish, the Vestry should be empowered to provide that supply, and not another public company; and entertaining this view, the application before the Board of Trade by the County of London Electric Lighting Company, Limited, for a provisional order under the provisions of the Electric Lighting Acts, 1882 and 1888, be opposed." After some discussion the motion was carried unanimously.

Barry Island Electric Railway.—In a parliamentary notice just issued, the Barry Dock and Railways Company give particulars as to the Bill for proposed electric tramway. The Bill provides for a tramway situate in the parishes of Barry, Merthyr Dovan, and Sully, commencing in the parish of Barry, at a point where the company's approach road to the Barry Station joins the road leading to Barry Harbour, extending thence along the said station approach road, thence in a north-easterly direction along part of Barry Dock road, and thence in a southerly direction over the company's western embankment to Barry Island and along Paget road, terminating in Paget road, near the beach of Whitmore Bay on Barry Island—a second tramway being situate wholly on Barry Island.

Fire Insurance Policies.—"A Solicitor" has the following letter in the *Times* of the 22nd inst., which it will be well for electrical companies and contractors to note: "Sir,—The recent fire in Regent-street, which, as I understand from the published accounts, is officially ascribed to 'overheating of electric wires,' is a fitting opportunity for directing attention to the question whether premises electrically lighted and their contents are covered by the ordinary fire insurance policies. I think it would be well for you to advise all persons who are having the electric light installed to get their existing fire policies endorsed by the offices 'electric lighting allowed,' otherwise, if a fire occurs, they may be met with a contention that they have added a new risk to the insurance which is not covered by the policy."

Cologne.—The cost of the Cologne installation for 20,000 lamps has amounted to £92,500, composed as follows: Buildings, machine room, boiler room, shaft, offices, £18,250; 10 boilers, £5,500; engines, dynamos, and switchboards, £32,500; mains and transformers, £31,000; meters, £2,000; works and various buildings, £2,500. The price of the installation per lamp is thus £4. 12s. 6d. The transformers reduce the pressure from 2,000 to 72 volts, varying from $1\frac{1}{4}$ to 25 kilowatts. The difference of potential between full and light load is about 2 per cent. The loss by hysteresis is: for $1\frac{1}{4}$ units 3.3 per cent., $2\frac{1}{2}$ units [illegible] per cent., 5 units 2 to 2.2 per cent., 10 units 1.7 to 2 per cent., and 25 units 1.2 per cent. The price of sale is equal to 9.6d. per unit, equal to ½d. a hour per 16 c.p., and 3½d. a hour for an arc lamp of 400 c.p. taking 350 watts, with discount for large quantities.

Proposed New Cable.—The Brazilian Submarine, the Western and Brazilian, and the West Coast of America Telegraph Companies, Limited, offer to the shareholders of their respective companies an issue at 102 per cent. of £100,000 4 per cent. guaranteed £100 debentures of the Pacific and European Telegraph Company, Limited. The debentures, which will be registered, are payable at the expiration of 50 years, but the company retains the right to pay them off at an earlier date at the price of £110. The proceeds of the debentures will be applied towards the maintenance and construction of a line of telegraph wires between Buenos Ayres and Valparaiso, with a branch between the latter place and Santiago, the capital of Chili, under concessions granted by the Argentine and Chilian Governments, thus, by means of the Montevideo and Buenos Ayres lines of the River Plate Telegraph Company, Limited, with which the Western Brazilian Company have a traffic arrangement, connecting the existing [illegible] and duplexed system of the Brazilian Submarine and Western Brazilian Companies with the cables of the West Coast Company, [illegible] between Valparaiso (Chili) and Lima (Peru).

Belfast.—The attention of Belfast has lately been directed to the question of electric lighting, and especially its adaptability to, and cost of production in, mills and factories have been favourably discussed by lecturers and writers in the press. A case in point is the adoption of the electric light in the York-road Mill of the York Street Spinning Company, Limited, of Belfast. In this mill an installation of 65 32-c.p. and 20 16-c.p. incandescent lamps, together with dynamo, has lately been erected and successfully set to work by Messrs. W. H. Allen and Co., of York-street, Lambeth, London. The dynamo has an output of 65 volts and 150 amperes when running at a speed of 700 revolutions per minute, and is furnished with a fast and loose pulley and a [illegible] or outer standard, with belt-tightening gear. The switchboard and connections are so arranged as to permit of the easy extension of the installation. The insulation of the cables and fittings is specially adapted to withstand the effects of the hot, damp atmosphere of the spinning room, and throughout the utmost care has been taken to adapt the method of lighting to the [illegible] of the case. The whole installation affords a fine illustration of modern mill lighting.

Reading.—Notice is given that application will be made to the Board of Trade on or before the 21st day of December next, by the Reading Electric Supply Company, Limited, a company registered under the Companies Acts, 1862 to 1890, with limited liability, and having its registered office at 2, Hungrave-street, Reading (hereinafter called the "undertakers"), for a provisional order (hereinafter called the "order") under the Electric Lighting Acts, 1882 and 1888. The following are the names of the streets within which the undertakers propose to lay down electric lines within a period of two years from the commencement of the order: [illegible] street, Broad street, Butter Market, Castle street, Duke street, Friar street, Gun street, High street, King's road (to where

Queen's-road joins it), King street, London-road (to where King's-road joins it), London street, Market place, Minster street, Oxford road as far as Howard-street, St Mary's Butts, West street. A map showing the boundaries of the area of supply will be deposited on or before the 30th day of November, 1892, for public inspection with the clerk to the local authority, at his office at the Town Hall, Reading, and with the clerk of the peace for the borough of Reading, at his office at 165, Friar street, Reading; and with the clerk of the peace for the county of Berks, at his office at 17, Friar street, Reading. Any objection must be addressed to the Board of Trade by January 15, 1893, and a copy must be served to either of the solicitors, H and C Collins, 2, Blagrave street, Reading; or Henry F. Kite, 11, Queen Victoria street, London, E.C.

Exeter. -At Exeter City Council last week, a letter was received from the Board of Trade, requesting to be furnished with any observations the authority might have to offer on a communication made to the Board by the Exeter Electric Light Company. The company are the undertakers to the Exeter Electric Lighting Order, 1891 and stated that the Council had recently had an application from the proprietor of two hotels within the area of supply mentioned in the order, for liberty to break up the public street between the two establishments, for the purpose of laying down an electric main. The Council decided to offer no objection thereto provided the roadway was restored to the satisfaction of their surveyor. The directors of the company did not think it fair that permission should be given to break up the public streets and lay down electric mains to anyone who chose to apply. They understood the Board of Trade had been advised that local authorities had no power to grant such permission to persons or companies holding any license under the Electric Lighting Acts. If this was the case, they asked that the fact might be communicated to the Council. It was decided to acknowledge the receipt of the letter without offering any observations upon it. Another letter from the secretary to the company informed the Council that a cheque for £350, on account of the claim for breaking up the streets for the purpose of laying the electric mains, had been paid to the city treasurer. Alderman Daw asked if the mains had been completed, as the sooner the poles were removed the better it would be for the town. The town clerk said he only knew that some of the overhead wires had been taken down.

Parliamentary Notices. -The issues of the *London Gazette* just lately have been filled with parliamentary notices of various kinds, some of which are of interest to electrical engineers, such as

BOLTON.—For the power to obtain the tramway system and to work it by any suitable method, electrical or otherwise.

NEWCASTLE ON TYNE.—To obtain a provisional order to authorise the Newcastle on Tyne Electrical Supply Company to extend their area.

BLACKPOOL CORPORATION.—Provisional order for extension of tramways.

GOOLE.—To authorise the Goole and District Gas Company, among other things, to obtain powers as to the supply of electricity.

THE LONDON COUNTY COUNCIL.—To take general powers as regards electric lighting, the words in the *Gazette* notice being: "To confer on the Council all necessary powers to enable them to provide and maintain an electric lighting installation on the Victoria embankment and the gardens thereon, and on the Westminster and Waterloo Bridges and neighbouring places, and for that purpose to empower the Council to generate and store electricity, and to use any lands for the time being belonging to them, and upon such lands to erect and maintain any necessary workshops, engine houses, storehouses (including places for storing electricity), or other buildings, and to manufacture, buy, or hire any machinery, steam engines, gas engines, or other apparatus and to take, hold, and use patent rights, or licenses, or authorities under letters patent for the use of inventions relative to the generation, utilisation, distribution, or supply of electricity or other lighting agent."

GLASGOW.—In relation to tramways and to telephone and telegraph wires.

Electric Tram Traction for Birmingham. The following is from the *Birmingham Daily Post*. "The opening of a line of electric tramway in South Staffordshire worked on the overhead wire principle, has revived the discussion as to whether it would be wise to allow the Central Tramways Company to substitute such a system of working for the use of steam on some of their lines. The overhead wire was thought objectionable on the Bristol road route because of its unsightliness, because it would have interfered with some of the trees and because electric wires carried in this fashion are often dangerous. Two of these objections would not, perhaps, apply in the same degree to a proposal to use it on certain other routes, and the objection founded on considerations of public safety appears to have been met in South Staffordshire in such a way as to satisfy Major General Hutchinson, the representative of the Board of Trade. In view of the congratulations offered by that gentleman to Mr Dickinson, engineer and general manager of the South Staffordshire Tramways Company, Mr Ebbsmith, chairman of the Birmingham Central Tramways Company, thinks it prudent to keep an open mind as to the advisability of using electric instead of cable traction on those routes which are affected by his recent proposals to form separate companies. If, he says, it could be used by means of an overhead wire, the Central Tramways Company would be 'a gold mine.' Cable traction is, of course, an economical thing to use, but the objection to it, especially in the present condition of affairs, is that it involves a large initial expenditure and a prolonged disturbance of the street surface, and consequent suspension of the company's traffic. The introduction of the overhead electric system is by comparison a cheap and simple matter. We understand that the Mayor and the Public Works Committee will be invited to visit Darlaston when the new service commences, so that they may judge how far it is adaptable for introduction in Birmingham. The safety of the system from an electrical point of view appears to be assured. The current is one of 300 volts only, and is continuous, not alternating. Mr. Edison has expressed the opinion that only under exceptional conditions can a current of 1,000 volts prove fatal; and Mr Dickinson states that while in Boston he saw a man take a current of 500 volts for the reward of a pint of beer, and that he did not seem to be dangerously or very painfully affected. But in order to meet any objection on this head, Mr. Dickinson has devised an arrangement by which the current ceases as soon as the wire breaks."

Electrical Trades' Union. -The head office of the Electrical Trades' Union established 1889, is at The Clarence Hotel, Aldersgate street, London, E.C. General secretary, A. J. Walker, 19, Claude road, Peckham, S.E.; president, Thomas Cannon, 1, Pullen buildings, Penton place, S.E.; executive council, H. Cork, T. Foster, W. Gooday, A. Hines, J. Moon, A. Norman, C. Thirlwell, W. Tabb. The union has now 28 branches, comprising 1,700 members. Branches are established in the following places: City of London, Manchester, Liverpool, Leeds, Dewsbury, Sheffield, Hanley, Bradford, Boston, Halifax, Croydon, East Greenwich, Kensington, Lambeth, Belfast, Preston, Glasgow, Newcastle on Tyne, Sunderland, Middlesbrough, West Hartlepool, Huddersfield, Nottingham, Derby, Blackburn, Salford, Hull, Leicester, Cardiff, Silvertown. Branches will be opened in the following towns shortly: Wolverhampton, Birmingham, Portsmouth, Devonport, Bristol. The benefits of this union are thus described: Out of work benefit, 2s per day, or 12s per week for 12 weeks; contingent benefit, special rates of pay for special cases; accident benefit, 10s. per week for 14 weeks, 7s. per week for a following 14 weeks; funeral benefit, on the death of a free member, £10, member's wife's death, £5; member's donation benefits are paid while on travel, and members are relieved from branch to branch. The entrance fee is 2s 6d, payable 1s on nomination and 1s. 6d on initiation, the contributions being 6d per week. This trades union was established in November, 1889. It was amalgamated with the Telegraph and Telephone Construction Men in December, 1890. The purposes for which the union was instituted are thus given: 1. For resisting any attempt to curtail or take away any of those privileges which are or may become the custom of the trade. 2. For assisting our members in recovering wages in dispute and obtaining justice against any unfairness practised towards them in their occupation. 3. For helping the members to obtain employment. 4. For giving relief to members when out of employment, or in distress, or in cases of accident whilst in the exercise of their calling, and paying a certain sum in the event of death. 5. For regulating the relations between workmen and employers. The following are eligible who are competent in one or more of the following branches: Armature magnet and transformer winders; erectors and tenders; installation linesmen and wiremen, indoors and out; battery accumulator makers, fitters, and inspectors; telegraph and telephone wiremen and linesmen faultfinders; instrument makers, installation attendants, land or sea, electrical traction employés, also labourers who have been employed for six months and upwards, whether telegraph, telephone, or electric light construction and maintenance.

Scarborough. -The Scarborough Electric Supply Company, Limited, has been formed with a capital of £50,000 in 5,000 shares of £10 each. The first issue has been made of 2,000 shares of £10 each, payable £2 on application, £2 on allotment, and the balance by instalments of £2 at intervals of not less than one month. The Directors are Lieut Colonel R F Steble, J.P., Ex Mayor of Scarborough; G. Alderson Smith, Esq., J.P., chairman of the Grand Hotel Company, Limited, and director of the Cliff Bridge Company, Limited, Scarborough; John Dale, Esq., J.P., Mayor of Scarborough; John Woodall Woodall, Esq., M.A., F.G.S., J.P., C.C., banker, Scarborough; George Lord Beeforth, Esq., J.P., Scarborough; John Bell Simpson, Esq., J.P., Hedgefield House, Blaydon on Tyne, director of the Newcastle and District Electric Lighting Company, Limited; the Honourable Charles A. Parsons, managing director of the Newcastle and District Electric Lighting Company, Limited; A. A. Campbell Swinton, Esq., Assoc.M.I.C.E., M.I.E.E. Managing director and consulting engineer: A. A. Campbell Swinton, Esq. Bankers: Messrs. Woodall, Hebden, and Co., Scarborough; Messrs. Lambton and Co., Newcastle on Tyne. Solicitors (*pro tem.*): Messrs. Leadbitter and Harvey, Newcastle on Tyne. Secretary (*pro tem.*): John Hall, Esq., 102, Westborough, Scarborough. Temporary Offices: 102, Westborough, Scarborough. The Company has been formed for the purpose of supplying electricity for lighting, motive power, and other purposes, in the town of Scarborough. The Corporation of Scarborough in the year 1891 obtained a provisional order (which was duly confirmed by Act of Parliament) enabling them to supply electricity within the borough of which they are the sanitary authority. It was, however, ultimately determined to transfer to other parties the powers, duties, and liabilities granted and imposed by the provisional order. Negotiations ensued, the result of which was that arrangements were entered into by the Corporation with Mr. A. A. Campbell Swinton, electrical engineer, of 66, Victoria street, Westminster, for the transfer to a company to be formed by him of the powers, duties, and liabilities of the provisional order. The Company has accordingly been formed for the purpose of providing the necessary capital, and the transfer will be made direct from the Corporation to the Company,

with the consent of the Board of Trade. The terms arranged with the Corporation comprise power for the Corporation to purchase the undertaking at the end of 21 years, 32 years, or any subsequent completed period of five years. If the Corporation exercise their option of purchase at the end of 21 years they are to pay the value of the undertaking as a current going concern, but without any allowance for compulsory purchase. If the option be exercised by them at the expiration of 32 years, or any later period, they are to pay for the undertaking the fair market value of all lands, buildings, works, materials, and plant suitable to and used for the purposes of the undertaking, regard being had to the nature and condition of such buildings, works, materials, and plant, and to the state of repair thereof, and to the circumstance that they are in such a position as to be ready for immediate working, and to their suitability to the purposes of the undertaking. The Company will pay to the Corporation the sum of 500 guineas to cover the expenses incurred by them in obtaining the provisional order. The maximum price of electricity for private consumers will be 7d. per Board of Trade unit, and for street lighting will be 6d. per unit. The price is to be reduced according to a specified sliding scale, which will not, however, come into effect until a cumulative dividend at the rate of £8 per cent. per annum has been paid to the shareholders. It is estimated that an expenditure of not more than £20,000 will be required to enable the Company to commence operations on a proper scale, and it is expected that the light will be turned on not later than the beginning of June next. It is proposed that the Company shall be worked upon the same lines, and with the same electrical system as the Newcastle and District Electric Lighting Company, Limited, of which the Hon. Charles A. Parsons, who is a Director of the Scarborough Company, is managing director. The Newcastle Company, which has only been in active operation a little more than two years, paid last year a dividend of 5 per cent. on its ordinary shares, besides placing a considerable sum to reserve and depreciation funds. The Directors have obtained the refusal of several suitable sites on reasonable terms. The Company will pay the expenses incidental to its formation, but no promotion money will be paid, and there will be no founders' shares. By the terms of the provisional order, the transfer to the Company must be effected by deed approved by the Board of Trade. The draft deed has been prepared, and a copy has been deposited at the office of the town clerk in Scarborough, according to the conditions of the provisional order. The Directors will themselves take not less than one-fifth of the first issue of shares. Applications for shares should be made not later than the 3rd December next.

PROVISIONAL PATENTS, 1892.

NOVEMBER 14.

20538. **Improvements in electrical cash or small parcel carriers.** James Heath Nicholson, of the firm of R. Waygood and Co., 17, Baronet road, Tottenham, London.

20590. **Means and electrical apparatus for preventing and killing blight on vegetation.** Robert Henelade Courtenay, 11, Lambourne road, Clapham, London.

20598. **Improvements in and relating to the manufacture of electric accumulators.** Charles Theryc and Alfred Oblasser, 45, Southampton buildings, Chancery lane, London.

20602. **Improved construction of electric bell push.** Charles Britcher, 9, Warwick court, Gray's inn, London.

20603. **Improvements in the fastenings of windows, doors, and other similar devices, and in electrical switches connected therewith.** David Lionel Salomons, 1, Queen Victoria-street, London.

NOVEMBER 15.

20606. **Improvements in electric arc lamps.** Charles Aubrey Day, 321, High Holborn, London. (The Higham Electric Company, United States.) (Complete specification.)

20610. **Improvements in telephone circuits.** George Lee Anders and Walther Kottgen, 10, Jeffrey's square, St. Mary axe, London.

20611. **Improvements in governing electric motors.** Benjamin Joseph Barnard Mills, 23, Southampton buildings, Chancery lane, London. (Robert Lundell, United States.) (Complete specification.)

20621. **Improvements in electric burglar alarms.** Homer Tong Wilson and Nathan Schwab, 4, Corporation street, Manchester. (Complete specification.)

20641. **The carriage electric light apparatus.** George Murray, 1, King street, Westminster, London.

20666. **An improved electromagnetic alarm or call.** Parnell Rabbidge, 6, Bream's buildings, Chancery lane, London.

20670. **Improvements in the arrangement of telephone circuits and switching devices therefor.** Sir Charles Stewart Forbes, Bart., 21, Finsbury pavement, London.

20693. **Improvements in electric arc lamps.** Fritz Hansen, 46, Lincoln's inn fields, London. (Complete specification.)

20698. **An improved electric arc lamp.** Henry Hungerford Boyle, 9, Warwick court, Gray's inn, London.

20700. **Improved means for lighting trains by electricity.** *Daniel Jones*, 9, Warwick court, Gray's inn, London.

NOVEMBER 16.

20729. **Improvements in dynamo-electric machines.** John Augustine Kingdon and Woodhouse and Rawson United, Limited, 88, Queen Victoria street, London.

20789. **A method of and apparatus for transmitting vocal and other sounds electrically.** James Geneve Lorrain, Norfolk House, Norfolk street, Strand, London. (Charles Clamond, France.)

20792. **An improved watchman's electric time recorder.** William Wilson Horn, 151, Strand, London. (Emanuel R. Heyser, United States.)

NOVEMBER 17.

20864. **Improvements in telephone transmitters.** Robert Peblitz, 76, Chancery lane, London. (Complete specification.)

20894. **Improvements in and relating to telegraphic or telephonic call systems.** Herman Wetzer, 18, Buckingham street, Strand, London. (Complete specification.)

20900. **An improved process of manufacturing and depositing spongy lead for secondary or storage batteries or receivers.** Ernest Bailey and John Dunham-Massey, 45, Southampton-buildings, Chancery lane, London.

20901. **Improvements relating to the electric lighting of railway carriages and other vehicles.** Ernest Bailey and John Dunham-Massey, 45, Southampton buildings, Chancery lane, London.

NOVEMBER 18.

20912. **Improvements in or connected with telephone apparatus.** Ridley James Urquhart, 5, Clayton square, London.

20959. **An improved electric arc lamp.** Frank West Suter and Sydney John Suter, 28, Southampton buildings, Chancery lane, London.

20964. **Improvements in electrical relays and apparatus for telegraphing to lighthouses either floating or on rocks at a distance from the shore or for telegraphing to and from vessels.** Willoughby Statham Smith and William Paddicombe Granville, 24, Southampton buildings, Chancery lane, London.

20989. **The detachable electric light bracket.** Albert Warren Upcraft, 5, Great Woodstock street, Marylebone, London. (Complete specification.)

NOVEMBER 19.

21020. **An electric-governed night latch.** Edwin Ward, 6, Argyle road, Nichol's Town, Southampton.

21041. **Improvements in and connected with electrometers and in their application to electric tramcars and locomotives.** John Augustine Kingdon, 20, Marlborough hill, London.

21074. **Improvements in galvanic batteries.** Frederick Culver James, 9, Quality court, Chancery lane, London.

21083. **Means for measuring or comparing sounds produced with telephones by the transmission of electric currents over a circuit.** John Edward Kingsbury, 24, Southampton buildings, Chancery lane, London. (The Western Electric Company, United States.)

SPECIFICATIONS PUBLISHED.

1892.

37. **Electric tricycles, etc.** Webb.
14886. **Electric switches.** Wright.
15059. **Electric incandescent lamps.** Glover.
17222. **Electric metal working.** Thompson. (Coffin.)
17226. **Welding metals electrically.** Thompson. (Coffin.)
17227. **Welding metals electrically.** Thompson. (Coffin.)
17242. **Electro-medical appliances.** Newton. (Carruthers.)
17304. **Electric heaters.** Ahearn.
17321. **Electric water heaters.** Ahearn.

NOTES.

Edison Lamp Patents.—The Edison companies are proceeding for an injunction against the Sawyer-Man Company.

Durham College of Science.—The foundation-stone of the new buildings of this college will be laid by the Earl of Durham on Monday next.

Church Lighting.—The Benedictine Abbey of Fort Augustus has the claim made for it as being the first Roman Catholic church lighted by electricity in the British Isles.

Junior Engineering Society.—A paper will be read before this society at the Westminster Palace Hotel on 2nd December by Mr. H. Fraser, on "Water-Tube Steam Boilers."

Niagara Observatory.—It is proposed to erect a steel observatory, 250ft. high, at Niagara Falls. Electricity will be largely used for the lifts and for the illumination.

Austrian Telephones.—The long-distance telephone line opened in October between Vienna, Gratz, and Trieste, in Austria, is the longest in Europe after that from Paris to Marseilles.

Chicago.—Correspondence from Chicago assures us that it is not, and never has been, the intention of the Chicago Exhibition authorities to close early in the evenings on weekdays.

Khotinsky Accumulators.—Captain Khotinsky is giving an exhaustive biographical account of the development of his accumulator in the pages of the New York *Electrical Engineer*.

Society of Arts.—Mr. James Dredge will read a paper before the Society of Arts on "The Chicago Exhibition" on Wednesday next, December 7, at 8 p.m. Sir Philip Cunliffe-Owen will preside.

Mains.—The question of underground mains is becoming a serious one in Paris, for we understand that more than one company have had to decide to reinstal the whole of their underground network.

Erba Prize.—The president of the Italian Electrical Society announces a prize of 500 lire with gold medal, to be awarded on January 10th, for a paper on "Comparative Study of the Bipolar and Multipolar Dynamo."

Speed and Power.—Sir Robert Ball calculates that if a spider's web belt travelled at the speed of light it would transmit 250 h p. If we can only get hold of the molecules—on Tesla's or other plan—what power may not be at our command

Smoking Concert.—Upwards of 100 of the London employés of the firm of Messrs. Drake and Gorham held their first smoking concert for the season on Wednesday evening. An excellent programme was provided, and a very enjoyable evening was spent.

The Hopkinson Case.—The suit of Hopkinson *v* The St. James and Pall Mall Electric Light Company has been again before the Courts, Mr. Moulton, Q.C., finishing his reply on behalf of the plantiff. Mr. Justice Romer said he would take time to consider his judgment.

Series Traction.—Mr. J. T. Sprague, speaking in a discussion at the American Institute of Electrical Engineers, said: "The series system of electric traction is absolutely dead in America, as in England. Mr. Short tried it a few years ago in Denver and West Virginia. It is now dead."

Skating by Arc Light.—Bitter cold prevails at Vienna, and the large skating-place behind the Art Museum is a brilliant scene by day and night with crowds of skaters, for in the evening 30 arc lamps are lighted, and the skimming figures glide here and there to the waltzes played by the military band.

Electric Pumping.—A paper was read by Mr. Maurice Deacon on "A Small Electric Pumping Plant" last January before the Chesterfield and Midland Counties Institution of Engineers. A discussion will be held on Saturday, the 3rd inst., on this paper, and also on the "Use of the Telephone," by Mr. F. S. Marsh.

Ozonators.—A Press view has been held in Liverpool to test Leather's ozonator and purifier—an apparatus fitted with an antiseptic chamber through which air is driven by an electric fan. The invention is stated to be used very largely for ventilating in the United States, and is being introduced into London and other large cities.

Two Motors or One.—Prof. Shepardson (America) says that a series of 12 tests on an electric tramway showed that 27 per cent. less current is used on the cars driving by one motor than when driving by two. The difference is attributable to the two being necessarily mostly at light load and lower efficiencies—also to the difficulty of running exactly together.

Local Electrical Industry.—We notice that the local papers are more and more taking to describing technical industries in their neighbourhood, great interest being taken in all electrical subjects. The Plymouth papers, for instance, this week describe the electroplating establishment of Messrs. Brock and Co., where a gas engine and dynamo are used for electroplating.

Electric Light for Balloons.—Some experiments of lighting the ground by means of balloons furnished with projectors of 5,000 c.p. have recently been carried out in Russia at the height of 2,000ft., and in spite of a thick mist the rays of electric light covered a surface of about 1,600ft. diameter. At 500ft. high a luminous ray could be projected fully lighting three-quarters of a mile of the route.

Overland Telegraph to Egypt.—Mr. Rhodes, at the meeting of the British South Africa Company, dealt with the question of an overland telegraph to Egypt. He had made a proposition to the Government that he would take a line through to Uganda at a cost of about £150,000. They would then be able to send messages at 1s. per word to Egypt and 1s. 6d. thence, instead of 9s. 6d. now charged by the cable companies.

Electric Heaters.—We have received a well illustrated list of Ahearn's electric heaters from the Railway Equipment Company, of Pall Mall-buildings, Chicago. A great deal of interest is being aroused in heating and cooking by these heaters in the same way that Messrs. Crompton are doing in England with the Carpenter heaters. The Ahearn electric stove is a very tasty adaptation, and will be sure to prove a useful piece of apparatus.

Utilising Water Power.—An eminent firm of engineers in Lancashire, we are told, are about to place before the public a new variety of methods of utilising water power. Instead of collecting the water of various streams into the reservoir, they seem to intend to use the power of each stream separately, and connect to a central station with accumulators. Except under very special circumstances we do not see great utility in the idea.

Electropathic Belts—We notice that the *British Medical Journal* is occupying its attention this week with reviews of two recently issued pamphlets by medical men on "electropathic" belts. The *Journal* questions the electrical knowledge of the authors, and entirely disagrees with the arguments, based upon a smattering of electrical know-

ledge, in which they claim efficacy for this apparatus in generating currents and, by implication, in curing disease.

Coast Communication.—Telephonic communication has now been established between the coastguard establishments at Margate, Ramsgate, and Deal, and preparations are being made for landing a cable from the East Goodwin lightship near Kingsdown and running a wire on to Dover. The disasters off this part of the coast have long rendered it most desirable that communication of the kind should be established, and its provision may result in the saving of many lives.

Laboratory.—At the meeting on the 9th inst. of the Société Internationale des Electriciens at Paris, M. Mascart gave an account of the efforts to establish an electrical laboratory for the society. The results have proved very satisfactory, the subscriptions having already amounted to 100,000 francs. MM. Weyher et Richemond have made a present to the society of a 25-h.p. engine, and M. A. Hillairet has undertaken to erect, free of cost, the whole of the mechanical part of the installation.

Telephone and Electric Waves.—M. Colson, in a note to the Académie des Sciences, deals with the use of the telephone in discovering electric waves, the method of which he had already communicated in a note (February, 1891) for an open circuit. He now studies this propagation in a closed circuit; he indicates the arrangement adopted and the results obtained. The telephone enables the interference to be clearly distinguished, and shows the influence of absorption and of the length of wave on this phenomenon.

Telephone Indicator.—An invention has been submitted to the French Minister of Commerce, to enable every subscriber to a telephone to know whether he has been called up in his absence, and by what subscriber. This is obtained by working the subscriber's call-bell in shunt off the central exchange battery. If the subscriber does not reply, the operator sends the whole current into the line, which actuates a Morse writer registering on a paper band the conventional signs designating the number of the subscriber who wished to speak.

Load Factor.—Various terms have been chosen by French electrical engineers to translate the term "load factor," invented by Mr. Crompton to express the important commercial relation, characteristic of a central station, between the electrical energy sold in a given time to that which the plant might be able to produce in the same time. The expressions *facteur de charge* or *coefficient de charge* have been proposed by M. Géraldy; but M. Hospitalier prefers *coefficient d'utilisation*, which seems sufficiently expressive and accurate, and will doubtless be adopted.

Wire-to-Wire Electric Communication.—Colonel J. R. Magrath, late assistant to the Director-General of Electric Telegraphs in India, writes as follows to the *Times* of Thursday: "Sir,—From the correspondence in the *Times*, it seems as if 'wire-to-wire electric communication' is looked upon as a new discovery. I beg to say that, before the mutiny in 1857, Sir William O'Shaughnessy, Director-General of Electric Telegraphs in India, made fairly successful experiments in this direction, which no doubt would have been continued and improved but for the mutiny needing our utmost efforts to keep the telegraph lines in working order."

Electrolytic Production of Chrome.—MM. Placet and Bonnet, says the *Bulletin Internationale*, obtain electrolytic deposits of chrome with a bath of 15 per cent. of sulphate of chrome slightly acidulated with sulphuric acid. Other baths are also used as follows: (1) Chrome alum 10 to 15 parts, sulphate of potash 10 to 15, oxalic acid 5, water 100 parts; (2) chromate of potash 10 to 15, chrome alum 15 to 20, water 100; (3) alum or fluosilicate of chrome 10 to 15, fluosilicate of ammonia 10 to 15, hydrofluoric acid 5 to 10, water 100 parts. Warm baths are preferable, and the same also for baths to which are added sugar, alcohol, or glycerine.

Aristol.—The chemical preparation known as aristol is the iodo-thymol prepared by making a solution of iodine in iodide of potassium act on a solution of thymol in caustic soda. The Farbenfabriken Company, of Elberfeld, states the *Revue de Chimie Industrielle*, has recently patented a process of electrolytic manufacture of this substance. A liquor is composed: of water 200, iodide of potassium seven, soda (in solution at 40deg. B.) 0.8, and thymol three parts. A current is passed through this liquid sufficient to give off six to eight centimetres of gas per minute. The aristol is formed at the positive pole; when the whole of the thymol is transformed the precipitate is collected, washed, and dried.

Train Lighting.—The makers of sets of train lighting plants, portable or otherwise, will have to keep their eyes open if they wish to show the railway companies what they can do. It is not every day that one can get managers of railway companies to look into schemes for better lighting, and the best time for mooting the subject is certainly when new enterprises are on hand. There are the new sleeping cars for the Compagnie Internationale des Wagons Lits—luxurious cars to take the traveller anywhere from Calais to St. Petersburg, in a miniature hotel. These are lighted by gas; they ought to be lighted by electricity. The company, no doubt, would if they could adopt the light. They should be shown the way.

Automatic Telephone Exchange.—An exchange for 80 subscribers, on the Strowger automatic system which we described recently, has been established at La Porte, near Chicago. It will be remembered that there are no telephone operators at all required on this system, each subscriber, by means of an ingenious piece of mechanism being able to switch himself on and off. The only attendant needed is a mechanic to keep the apparatus in repair. The exchange has already 24 subscribers, and a Press view, which created great interest, was recently held. The exchange works very satisfactorily. We ought to know something more about the system in this country, for if the practical difficulties do not prove too great, it might prove very remunerative for small exchanges.

Catalogue.—A handsome catalogue that has been forwarded to us for review is that of the Taunton dynamos from the Newton Electrical Engineering Works, of Taunton. An oil engine fitted with one of these dynamos on the same bed-plate is very useful for country mansions. A tramcar or launch motor of very compact type is illustrated, besides steam dynamos direct-coupled with engine and dynamo on the same bed-plate. Taunton dynamos of more than 100 amperes are fitted with Kapp's patent end connectors on the armature. We have already described the Newton-Hawkins brushholder and their automatic switch, their swinging switchboard and transformers. The firm are manufacturing good machines, and are rapidly taking a leading place as electrical engineers in the West of England.

Association of Central Station Engineers.—Central electric station engineers are, as a rule, the most modest of men. It is seldom we hear of their work, probably because they are so busy. But the time is rapidly approaching when there will be a really useful purpose served in occasional gatherings for the publication of methods and results and the exchange of ideas. The scheme has long been favoured in America, where annual

gatherings of those in command are held with good practical result. The difficulties are not so great in England for such a *réunion*, and one of the things most desired is full and carefully gathered up-to-date information of the practical nature that those in command of stations can give. There are now sufficient central stations at work, or being erected, for such a proposal to prove useful.

Council and Officers of the Institution.—The following is the proposed list of Council and officers of the Institution of Electrical Engineers, to be balloted for on Thursday, December 8: President, W. H. Preece, F.R.S. Vice-presidents (four to be elected): Alexander Siemens; R. E. Crompton, M.I.C.E.; Sir David Salomons, Bart., M.A.; Sir Henry Mance, C.I.E., M.I.C.E Ordinary members of Council: Major G. W. Addison, R.E.; Prof. J. A. Fleming, M.A., D.Sc.; Prof. George Forbes, F.R.SS. (L. and E.); Edward Hopkinson, M.A., D.Sc.; Colonel R. Raynsford Jackson; Prof. A. B. W. Kennedy, F.R.S., M.I.C.E.; W. M. Mordey; Prof. John Perry, D.Sc., F.R.S.; James Swinburne (remaining on Council); Frank Bailey; Walter T. Goolden, M.A.; Gisbert Kapp, M.I.C.E. Associate members of Council: W. A. Chamen; C. P. Sparks; Arthur Wright. Honorary treasurer: Sir David Salomons, Bart., M.A., vice-president.

Rome Exhibition.—After some little difficulties, which have now been satisfactorily surmounted, the project for holding in Rome in 1895-96 an International Exhibition of Fine Arts and Electricity, says the *Daily News*, is well under way. It is intended to solemnise the twenty-fifth anniversary of the annexation of Rome to the kingdom of Italy. Owing to the indifferent financial condition of the municipality, as well as to the fears which were entertained that the result would not have proved a successful one, subscriptions came in at first very slowly; but the idea of holding the exhibition gradually made progress, and the civic authorities have made over to the committee the grounds on which the exhibition buildings are to rise. This site is in the vicinity of "Ponte Milvio," about a mile's distance from "Porta del Popolo," in a very attractive position, bordering on the river, and commanding a fine view of the Sabine Hills.

Measurement of Magnetic Fields.—At the French Académié des Sciences on the 16th inst., M. Adolphe Berget read a paper on "The Measurement of Magnetic Fields." It is known that M. Fizeau employed the measure of the edges of thin plates to determine the value of the theoretical expansion of metals. M. Berget has had the idea of applying this delicate method of measurement to measure the expansion of iron in a magnetic field which can be varied in intensity. As soon as the current passes the edges are displaced, and take the normal position on breaking the current. The lengthenings have been thus measured of two ten-thousandths of a millimetre for a given intensity, and measured for intensities up to tenfold. The law of the variations of length is given by an exponiential formula. Neither Wertheim nor Wiedemann, who studied these delicate questions, ever thought that such small measurements could be made.

Increased Telephonic Charges.—At a meeting of the Executive Committee of the Hull Guardian Society held last week it was stated that the Government had taken over the trunk lines of the National Telephone and Western Counties Companies, and that notice had been received of their intention to raise the charge for a three minutes' conversation between town and town, from the present rate of 6d. to 1s. 6d. from January 1 next. The autumnal meeting of the Associated Chambers of Commerce had already passed a resolution in opposition to the proposed increase, and it was stated that this step had been resolved upon to enable the Government to make up for the falling revenue of the Telegraphic Department. The members of the Hull society were of opinion that the enhanced rate would block the present easy facilities for commercial conversation; but it was decided to await further information before taking any definite steps to join a deputation to the Postmaster-General.

An Electrical Detective.—Boot dealers in Paris, says the *Shoe and Leather Record*, who expose their goods outside their shops appear to be liable to the same kind of depredations as with us. Recently a retailer in that city who had for some time past been subject to so many mysterious pilferings that his losses became serious, hit upon an ingenious application of electricity for the detection of the thief. He so arranged his goods at the more exposed corners that certain pairs were placed in connection with the wire of an electric bell. One morning as he was sitting at breakfast he heard the bell ring suddenly, and, hurrying out, saw a young man running away at full speed. But the shoemaker was a better runner than the thief, whom he overtook and secured. The prisoner told the old story that he was only examining the goods with a view to buying them. But it happened that upon being searched he was found to have only four sous in his possession, and the Commissary of Police naturally declined to accept the explanation.

Electricity in Mining.—Prof. Robinson delivered a lecture on Saturday afternoon in the large theatre of Nottingham University College on "Electricity, as Applied to Mining." The lecture was one of a series arranged by the midland counties branches of the National Association of Colliery Managers, in conjunction with the Technical Education Committee of the Notts. and Derbyshire County Council, for the benefit of mining engineers, colliery managers, deputies, and others. Prof. Robinson, in his opening remarks, said that, for practical mining, the uses of electricity were daily increasing, and it was becoming a more and more useful agent in the coal mine. A number of experiments were given illustrating the usefulness of electricity in mines, and the speaker dealt with the general application of electric power in mines, for lighting, pumping, and hauling, economy in the transmission and distribution of electric power, the measurement of power, and the advantages of electric plant. The lecturer received a hearty vote of thanks.

Obituary.—The death is recorded of Prof. Chas. A. Seeley, for many years a member of the editorial staff of the *Scientific American*, and one of the founders of the American Electric Light Company. In the early days of dynamo design, Dr. Seeley devoted much attention to obviating the loss of energy in the iron core of the armature. He enunciated the theory that the loss resulted from a twofold cause: the so-called Foucault currents, and a second cause then unrecognised, but since named hysteresis by Prof. Ewing. His theories are now generally adopted, and due credit should be given to this investigator. His theories resulted in the design of a coreless disc armature, which was exhibited at the first Paris Exhibition, and again at the Crystal Palace Exhibition of 1882, where the exhibitors received a gold medal. He was a member of the American Association for the Advancement of Science, and of the American Institute. His scientific knowledge was very wide, embracing, besides electricity, chemistry, in which he was an expert.

Technical Education. — The address by Mr. Llewellyn Smith before the London Chamber of Commerce on Wednesday, went to show very forcibly what large strides are being taken all over the country in the

matter of technical education. The one lagger behind was London, and it is probable that the London County Council itself may soon be in the van of progress. The time lost in waiting may not be entirely wasted, and we may see a scheme for London eventually carried that will redound to its credit. It is to be hoped that everyone with any influence, or means for making the scheme perfect at their disposal, will aid in every way the project for the establishment of real technical and commercial education for London. There should be no longer, on the one hand, a mere tinkering on the outskirts of technical training, and on the other, no losing the way in the slough of despond under South Kensington rule, but a well-considered scheme which will serve to put England, and especially London, in the front rank in this direction. The time for organising is now with us. In a few years it may be too late to reconsider the question.

Guttapercha.—M. Leon Brasse (in *Electricité*) has a study on the production of guttapercha. He comes to the conclusion that all guttas of superior quality have a weak specific resistance, and it is not at all demonstrated that they are the product of trees of the genus Dichopsis; that the gutta from Pahang, the product of the Dichopsis oblongifolium, is a guttapercha of average quality—its specific resistance being sufficiently high; the bolungan and coti guttas used in the past have a low specific resistance, those we are now using have one which gets higher and higher, and it is necessary to be very careful in their use; the white guttas all present a high specific resistance, they cannot be employed alone, nor in large proportion, for the manufacture of cables; lastly, he does not think that it should be the product of a Dichopsis which, as maintained, has been exclusively used as dielectric for submarine cables, as its resistance always rises to about 400 × 10^6 megohms, and he does not know a cable of English manufacture whose specific resistance exceeds 120 × 10^6 megohms. The best qualities, M. Brasse thinks, are those of Pahang, Sarawak, and Sandakan. It would seem well, before adopting and planting a Dichopsis gutta or oblongifolium, whose output is so small, to make search near Pahang and the north of Borneo and verify the assertions of M. Leys relative to these latter regions. The importance of the capital which it is necessary to sink in plantations for some years necessitates absolute surety of the result to be achieved.

Ward Leonard System.—Mr. H. Ward Leonard's system of double generator motor driving for electric cars was severely criticised by Dr. Hutchinson at the discussion of the railway papers, at the American Institute of Electrical Engineers, principally on account of cost. The combined efficiency of the Leonard system, claimed for 54 per cent., would, he maintained, come to only 37·6 per cent., or with field losses 33 per cent., as against 27 per cent. with commutated fields, a saving hardly worth the complication. As regards power at the power-house, Mr. Leonard's proposition of 6 h.p. steady demand per car he thought would not be enough; the idea of going only three miles an hour uphill would not meet the wishes of managers. Many plants were being put in now with 60 h.p. per car, as it was found fully 40 h.p. was required going uphill at speed. The cost he also makes double Mr. Leonard's figures, and points out that the extra weight would also necessitate the consumption of more power. Mr. Ward Leonard, replying to this, said, with regard to efficiency, accurate tests had been taken by William Sellers and Co., of Philadelphia, and the efficiencies claimed have been well borne out. With regard to power, he did not maintain that 6 h.p. would be sufficient for a car, but that 6 h.p. per car would be an average figure, some taking more and some less. It was evident if large changes of load could be avoided the cost of power plant would be less; in fact, his experience on cranes and elevators lead him to believe it would be just half. The cost of motors is not so important as would at first seem. In a plant he was designing they came to 5 per cent. of the whole cost. If they amounted to even 10 per cent. of the whole, with advantage of using engines at full load, it would still pay to use his method. With reference to depreciation, he found in practice the machinery on the system requires very little attention. There is only one lever to accomplish all changes of speed. The electric brake used returns energy to the line while stopping the car. The use of secondary line enables engineers, if desired, to use 1,000 volts in the trolley line while sending only 300 or 500 volts into the propelling motors. The principal point is the flattening of the load diagram, which means the halving of the cost of engines and dynamos, and a very great increase in efficiency, both in the engines and by the energy returned to the line. The system is to be tried shortly on a street-car line.

Balancing Armature Reactions.—To lead the armature current by special wires through slots on the surface of the pole-pieces is the method which is being investigated by Harris J. Ryan (*Sibley Journal of Engineering*, reproduced in *Electrical World*, November 19th), for obviating the magnetising effects of the armature currents in the magnetic field. Mr. Ryan, in conjunction with Mr. M. E. Thompson, has made six machines with slotted pole pieces, two of which have been tried, and other results are to be published. The details of the second machine are thus given: output, 40 amperes, 100 volts at 1,200 revolutions; type four-pole, field of cast iron in two pieces, armature, drum winding through 58 grooves, five No. 10 B. & S. wires each groove, winding in two circuits, 29 commutator bars; grooves, ⅝in. by $\frac{3}{32}$in., outside diameter of core 7⅛in., inside 3in., built of discs, length of armature and poles, 6in. each. Effective length of iron in armature core, 5in. Magnetic leakage 1[illegible] per cent. Field cores, 5in. by 2in., rounded ends, area, 9·14 square inches. Mean length of field, magnetic circuit, 12·5in. Magnetic density in armature core, 5,400; in air gap, 4,900; in armature lugs, 8,400; in field cores, 6,[illegible]. Field winding—mean length of turn, 15in. Requisite exciting E.M.F. for field, 910 ampere-turns; armature, 25 ampere-turns; air gap, 1,000 ampere-turns—or a total of 1,935 ampere-turns. Requisite size of wire for excitation at 100 volts, 1,575 circular mils; size adopted, No. 1[illegible] B. & S.—of this enough was wound to bring exciting current density down to 1,000 circular mils per ampere. Weight of completed machine, 400lb. The number of special balancing conductors in each pole face is given by the following proportion: The product of the armature conductors under a pole into the current in the same is equal to the product of the balancing conductors back of each pole face in the current (total armature current) through them. It will be seen no regard is made for the pernicious effects usually present with so short an air gap with so large a number of ampere-turns. No such effects were observed in this machine. The machine could be loaded to 100 amperes with no fall of potential at brushes, except that due to ohmic resistance—there was no shifting of the neutral point. All cross induction may be avoided or even reversed in its effects. The output for given weight may be largely increased over that realised in the common practice of to-day. The air gap may be made as small as mechanical requirements permit, thus enabling one to realise the advantages of differential excitation so successfully utilised in the modern alternate-current transformer.

OUR PORTRAITS.

Volk, Magnus, A.I.E.E. Born at Brighton in 1851. From his earliest days he was interested in electrical and general engineering work. Owing to the death of his father (a clever mechanician) he was thrown upon his own resources at an early age. His first commercial venture was the introduction of a model telegraph instrument, of which about 60,000 were sold in a short time. He was then employed by Captain Harvey, who was then developing his "towing torpedo." This led to his introduction to Messrs. Vavasseur and Co., for whom, under Captain McEvoy, he constructed and devised considerable quantities of torpedo apparatus. The converting of the Martini Henry rifle into a magazine gun was then taken in hand, and, when nearly completed, a sudden and nearly fatal illness in 1891 caused the loss of the business, and necessitated a fresh start. This occurred in connection with the United Telephone Company, who placed the opening up of Brighton and the surrounding district complete with telephone exchanges in his hands. This was successfully accomplished and Brighton connected with London by a trunk wire; he also designed complete exchange switchboards and various switches and bells for subscribers' use. The lighting up of his factory and private house by electricity led to his obtaining the order to light the Royal Pavilion, Brighton, for the Corporation, with an installation of 1,100 lamps, probably the largest installation in the country at that date—April, 1883. The electric transmission of power was next experimented with on a strip of ground under the sea-wall at Brighton, a small electric railway being constructed and worked, it being the first public electric conveyance opened in this country – August, 1883. This proving very successful, application was made to the Corporation for extension and reconstruction on a larger scale. This was carried out amid a perfect storm of opposition from cabmen and others prejudiced against any innovation. These obstacles were, however, overcome, and although repeatedly damaged by gales, has continued running successfully till the present time. It is now being converted to the third-rail system, and new rolling-stock is being constructed. He has been and is a contributor of various articles to the technical journals. Mr. Volk is now taking Mr. H. Hewett and his son as partners—the firm being under the style of Hewett, Volk, and Hewett, the object being to obtain statutory powers and construct and work electric railways, etc.

Capito, Chas., M.Inst.Mech.E., M.Inst.Elec.E., was born and educated in Copenhagen. He served his apprenticeship as a mechanical engineer and studied for several years at the technical college in his native town, out of which he passed with honours. Mr. Capito was for some time consulting engineer to the Cryolite Mining Company, of Copenhagen, and spent a year at this company's mines in Greenland, where he was occupied in making a survey of the mining district, and also in the construction of new machinery. In 1880 Mr. Capito came to England, and was soon after appointed assistant to Prof. W. E. Ayrton, F.R.S., at the City and Guilds of London Institute. No doubt many of our readers will remember Mr. Capito from the time when they attended the course of electrical engineering at the Cowper-street School. In 1882 Mr. Capito accepted the appointment as chief electrical engineer to the Electrical Power Storage Company, Limited. He was the technical representative of this company in New York, Vienna, and Berlin. Subsequently Mr. Capito joined the well-known School of Electrical Engineering, then under the management of the late Mr. Lant Carpenter, and has thus had a very prominent position in the training of the younger generation of electrical engineers, upon whose work the success of the industry to a great extent depends. Mr. Capito has for some years been established as a consulting engineer.

Joel, Henry Francis, commenced his career as an architect. At the age of 14 he was articled as a pupil to Mr. J. Tanner, F.R.I.B.A., with whom he served three years—from 1865 to 1868. He then entered into the engineering profession as assistant to Mr. Robert Sabine, C.E. and electrician, and also became a seven years' student in the Institution of Civil Engineers, during which time he obtained a Miller prize. As assistant to Mr. R. Sabine and Mr. Latimer Clark, he carried out the work of laying the Pneumatic Despatch Railway in London, as well as the electrical testing of several submarine telegraph cables. Mr. Joel first became connected with electric lighting in the year 1870, when he was assistant to the late Sir Charles Wheatstone, F.R.S., at his electric telegraph factory, where electric light apparatus and Gramme dynamo machines were made. During this period Mr. Joel assisted to fit up the 20,000-arc lamp tried on the clock tower of the House of Commons. He remained with Sir Charles Wheatstone until 1873. In 1873 and 1874 he took charge, for Sir Samuel Canning and Mr. Sabine, of the electrical testing, and served as electrician during the laying in the West Indies of a submarine telegraph cable of 740 knots in length. In 1877 he was elected an associate of the Institution of Civil Engineers. In 1878 Mr. Joel entered into partnership in a signal engineering business with Messrs. Latimer Clark, Muirhead, and Co., of Westminster, and whilst conducting that business became acquainted with Mr. Werdermann. Mr. Joel suggested and made various important improvements in the Werdermann lamp, and brought that lamp prominently into notice. He invented and patented his own semi-incandescent lamp, amongst many other inventions, in 1879, and has since that year been exclusively engaged in electric lighting, fitting up installations and perfecting a dynamo machine with detachable coils on the armature, and other improvements. Mr. Joel's lamps were exhibited in practical action at the Paris Electrical Exhibition of 1881, where they were awarded a silver medal. In the Crystal Palace Electrical Exhibition of 1882, the Joel lamps were shown in the Pompeian Court, and were awarded a gold medal. In May, 1882, the Pilsen-Joel Electric Light Company was brought out. Mr. Joel held the position of managing engineer to that company, and planned their very large factories in Kentish Town. Mr. Joel resigned his position with the company in September, 1883, and started in business for himself as an electric light engineer. As electrical engineer to the Leeds Corporation he supervised the electric lighting of the municipal buildings at Leeds, as well as other electric light installations. Mr. Joel is now carrying on a business as electrical engineer in Wilson street, Finsbury, E.C., and has patented many interesting inventions—amongst others, a meter for electric light, a new motor with laminated fields and armature, and a special arrangement of the fields for alternating-current circuits.

Newton, Francis Murray. Born 1852, at Barton Grange, Taunton. Educated at Eton and Oxford, of which university he is a graduate. Whilst studying physical science under Prof. Pritchard and Prof. Clifton, he was selected as one of the observers on the Government expedition in 1874 to observe the transit of Venus across the sun at "Station A," near Cairo. Whilst there, in addition to the ordinary work of an observer, he was responsible for the care of all the clocks and chronometers on which the accuracy of all the results to be obtained depended, for the meteorological instruments and observations, and also had general charge of the telegraphic instruments and their operation, by means of which signals were transmitted between Greenwich Observatory and "Station A," and the exact longitude of the latter determined. In consideration of these services he was elected a Fellow of the Royal Astronomical Society. After serving an apprenticeship to Messrs. Easton and Anderson, Erith, he was elected an associate of the Institute of Civil Engineers, and appointed Instructor in Practical Mechanics at Eton College, which post he held for two years. He then devoted himself entirely to electrical work, although he had made his first dynamo in 1879, and having patented several modifications of dynamos and arc lamps, he went, in 1881, for a short time to Messrs. Woodhouse and Rawson, and was afterwards appointed manager of the Belfast Electrical Appliances Company, Limited, where he brought out the well-known Belfast arc lamp, and a good practical form of open-coil dynamo, many of which are doing good work at the present day, and obtained for his firm the bronze medal at the Cork Electrical Exhibition. Resigning this appointment,

he started a business on his own account at Taunton, devoting himself chiefly to the improvement and manufacture of the dynamo; here he has from time to time built new works, and is at present proprietor of the Newton Electrical Engineering Works adjoining the G.W.R. Station.

Offer, George. Born in London in 1827. It was not till the year 1878 that Mr. Offer turned his attention more directly to electrical matters, and became the English agent for Schuckert. The following year he became connected with the Anglo American, which has subsequently developed into the Brush, and was for a time busily engaged in installation work and in the negotiations for concessions, becoming general manager of the subsidiary South Eastern Brush in 1882, but in 1883, on the formation of the Consolidated, Mr Offer undertook the management of this company, and under this management the B.T.K. system was tried at Colchester. Mr. Offer was one of Lord Thurlow's committee for obtaining an amendment of the Electric Lighting Act of 1882. Under the auspices of the Electric Installation Company, and Mr. Offer's management (although the concerns are now separate companies), the Sydenham hill central station was built and the Crystal Palace District Company formed. Similar work was done at Oxford. Both these stations have been described in our columns, and we understand that the Oxford installation especially is making good headway. It will be seen that Mr Offer has imparted a vast amount of energy into his electrical work, and it is to be hoped the results will be commensurate with the energy displayed.

ON THE ATTRACTION OF INFINITE ELLIPTIC CYLINDERS.*

BY GEORGE A. GIBSON, M.A.

The expressions for the attraction of infinite elliptic cylinders are usually deduced from the formulas for the attraction of ellipsoids. In this paper I propose to consider the attraction of cylinders without reference to the more general case of ellipsoids; the solutions I give follow immediately from the values of certain integrals which I have given in a paper in the tenth volume of the *Proceedings* of the Edinburgh Mathematical Society.

1. The attraction of a thin rod, infinitely extended in both directions, and of mass k per unit of length is $2k/r$, r being the distance of the attracted point from the rod. Now, suppose we have a cylinder infinitely extended in both directions, and we take as axis of z a line parallel to the generators of the cylinder. The resultant attraction at any point will be in a plane perpendicular to the generators; this plane will be taken as that of xy. Let (x, y) be the co-ordinates of the attracted point, (x', y') those of a point in the section of the cylinder made by the plane of xy, dS a small area round (x', y'), $\rho\, dS$ the mass per unit length of the thin cylinder, having dS for section, and having its generators parallel to the axis of z, and r the distance between (x, y) and (x', y'). The components of the attraction towards the origin will be given by

$$X = 2\int \frac{x - x'}{r^2}\,\rho\, dS\,;\; Y = 2\int \frac{y - y'}{r^2}\,\rho\, dS\,,$$

where the integrations extend over the section of the cylinder made by the plane of xy. If we put $V = 2U = 2\int \log \frac{1}{r}\,.\,\rho\, dS$, we get $X = -2\frac{dU}{dx}$, $Y = -2\frac{dU}{dy}$.

The function U is generally called the logarithmic potential. Like the ordinary potential, it satisfies Poisson's equation (with $2\pi\rho$ instead of $4\pi\rho$, since $U = \frac{1}{2}V$), but it does not vanish for $r = \infty$. If R be the distance of (x, y) from a fixed point at a finite distance from the origin, the limit when R is infinite of $U \div \log\frac{1}{R}$ is equal to $\int \rho\, dS$, that is, to the quantity of matter in unit length of the cylinder. Further, U and its first differential coefficients are finite and continuous.

The most convenient co-ordinates for present purposes are the parameters of the confocal ellipses and hyperbolas passing through a point, and throughout the paper I use the following notation—$2c$ is the distance between the foci of the section of the cylinder, supposed to be elliptic

$$x' = c\cosh u \cos\theta \qquad x = c\cosh v\cos\phi$$
$$y' = c\sinh u\sin\theta \qquad y = c\sinh v\sin\phi$$
$$dS = \tfrac{1}{2}c^2(\cosh 2u - \cos 2\theta)\,du\,d\theta.$$

Any ellipse will be determined by the parameter u. When the section is bounded by two confocal ellipses, λ and μ will be taken for the parameters of the outer and of the inner respectively, and the semi-axes will be given by $a = c\cosh\lambda$, $b = c\sinh\lambda$, $a' = c\cosh\mu$, $b' = c\sinh\mu$. The values $\alpha = c\cosh v$, $\beta = c\sinh v$ will also be used, so that $x = \alpha\cos\phi$, $y = \beta\sin\phi$.

An arc of the ellipse v = constant, and of the hyperbola ϕ = constant, will be given by $J\,ds_1 = d\phi$, $J\,ds_2 = dv$, where

$$1/J^2 = \tfrac{1}{2}c^2(\cosh 2v - \cos 2\phi).$$

Usually, it will be considered sufficient to determine U, as the attractions can be found from that by differentiation. The integrations that occur follow so directly from the formulas of the paper referred to above, that I have thought it unnecessary to reproduce them.

2. The section bounded by two confocal ellipses λ, μ $(\lambda > \mu)$, and ρ constant.

(i.) The attracted point, P (x, y) or (v, ϕ), outside the area, so that $v > \lambda$.

$$-2U = \pi\rho c^2(\sinh 2\lambda - \sinh 2\mu)\left(\log\frac{c}{2} + v + \tfrac{1}{2}e^{-2v}\cos 2\phi\right)$$
$$= \pi\rho c^2(\sinh 2\lambda - \sinh 2\mu)\left(\log\frac{\alpha + \beta}{2} + \tfrac{1}{2}e^{-2v}\cos 2\phi\right)$$

since $v = \log e^v = \log(\cosh v + \sinh v)$; and, therefore

$$\log\frac{c}{2} + v = \log\frac{\alpha + \beta}{2}.$$

If A be the area of the section, $A = \frac{1}{2}\pi c^2(\sinh 2\lambda - \sinh 2\mu)$;

$$\therefore\ U = \rho A\log\frac{2}{\alpha + \beta} - \tfrac{1}{2}\rho A e^{-2v}\cos 2\phi$$

In this case λ and μ occur only in the factor A, so that U, and therefore the attraction, is the same whenever the area of the section (bounded by two confocals) is the same.

(ii.) The attracted point, P, in the hollow so that $v < \mu$.

$$-2U = \pi\rho c^2(\sinh 2\lambda - \sinh 2\mu)\log\frac{c}{2} + \pi\rho c^2(\lambda\sinh 2\lambda - \mu\sinh 2\mu)$$
$$-\tfrac{1}{2}\pi\rho c^2(\cosh 2\lambda - \cosh 2\mu) - \tfrac{1}{2}\pi\rho c^2(e^{-2\lambda} - e^{-2\mu})\cosh 2v\cos 2\phi$$

If this be expressed in terms of the axes and of x, y, we get

$$U = \pi\rho ab\log\frac{2}{a + b} - \pi\rho a'b'\log\frac{2}{a' + b'} + \tfrac{1}{2}\pi\rho(ab - a'b')$$
$$+\tfrac{1}{2}\pi\rho\left(\frac{a - b}{a + b} - \frac{a' - b'}{a' + b'}\right)(x^2 - y^2).$$

(iii.) P in the attracting mass, so that $\lambda > v > \mu$.

$$-2U = \pi\rho c^2\{\lambda\sinh 2\lambda + (\sinh 2\lambda - \sinh 2\mu)\log\frac{c}{2} - \tfrac{1}{2}\cosh 2\lambda\}$$
$$-\tfrac{1}{2}\pi\rho c^2 e^{-2\lambda}\cosh 2v\cos 2\phi - \pi\rho c^2\sinh 2\mu\,(v - \tfrac{1}{2}e^{-2v}\cos 2\phi)$$
$$+\tfrac{1}{2}\pi\rho c^2(\cosh 2v + \cos 2\phi);$$

or,

$$U = \tfrac{1}{2}\pi\rho(a^2 + b^2) + \pi\rho ab\log\frac{2}{a + b} - \pi\rho a'b'\log\frac{2}{\alpha + \beta} + \tfrac{1}{2}\pi\rho a'b' e^{-2v}\cos 2\phi$$
$$+\tfrac{1}{2}\pi\rho(a - b)^2\cosh 2v\cos 2\phi - \tfrac{1}{2}\pi\rho c^2(\cosh 2v + \cos 2\phi)$$

CHARLES CAPITO.

If the cylinders be circular, the expressions for U are easily deduced from the above. If D be the distance of P from the axis, they are as follows:

(i.) $U = \rho A \log \frac{1}{D}$.

(ii.) $U = \pi \rho a^2 \log \frac{1}{a} - \pi \rho a'^2 \log \frac{1}{a'} + \frac{1}{2} \pi \rho (a^2 - a'^2)$ = constant.

(iii.) $U = \pi \rho a^2 \log \frac{1}{a} - \pi \rho a'^2 \log \frac{1}{D} + \frac{1}{2} \pi \rho (a^2 - D^2)$;

since $b = a$, $b' = a'$, $\beta = \alpha = D$.

3. To find the components of the attraction in the cases just considered.

If N and T be the normal and tangential components respectively, $N = -2 J dU/dv$, $T = -2 J dU/d\phi$, and the resultant $R = \sqrt{N^2 + T^2}$. If the components parallel to the axes be wanted, then denoting by n the angle which the normal to the ellipse v at the point ϕ makes with the axis of x.

$$X = N \cos n - T \sin n, \quad Y = N \sin n + T \cos n,$$

where $\cos n = J c \sinh v \cos \phi$, $\sin n = J c \cosh v \sin \phi$.

After some reductions we get the following values:

(i.) $v > \lambda$.

$$X = \frac{4 \rho A}{c} e^{-v} \cos \phi, \quad Y = \frac{4 \rho A}{c} e^{-v} \sin \phi,$$

$$R = \frac{4 \rho A}{c} e^{-v}.$$

Hence R is the same for all points on the ellipse v, and its direction makes with the axis of x an angle ϕ.

(ii.) $v < \mu$.

$$X = -2 \frac{dU}{dx} = -2 \pi \rho \left(\frac{a-b}{a+b} - \frac{a'-b'}{a'+b'} \right) x.$$

$$Y = -2 \frac{dU}{dy} = 2 \pi \rho \left(\frac{a-b}{a+b} - \frac{a'-b'}{a'+b'} \right) y.$$

$$R = 2 \pi \rho \left(\frac{a-b}{a+b} - \frac{a'-b'}{a'+b'} \right) \sqrt{x^2 + y^2},$$

and the direction of R makes with the axis of x the angle $\tan^{-1}(-y/x)$.

(iii.) $\lambda > v > \mu$.

$$X = 2 \pi \rho c \left\{ \left(1 - e^{-2\lambda} \right) \cosh v - e^{-v} \sinh 2\mu \right\} \cos \phi.$$

$$Y = 2 \pi \rho c \left\{ \left(1 + e^{-2\lambda} \right) \sinh v - e^{-v} \sinh 2\mu \right\} \sin \phi.$$

The value of R in this case is somewhat complicated, but if $\mu = 0$

$$X = 2 \pi \rho \left(1 - e^{-2\lambda} \right) x = 4 \pi \rho \frac{b}{a+b} x$$

$$Y = 2 \pi \rho \left(1 + e^{-2\lambda} \right) y = 4 \pi \rho \frac{a}{a+b} y.$$

$$R = 4 \pi \rho \frac{ab}{a+b} \sqrt{\left(\frac{x^2}{a^2} + \frac{y^2}{b^2} \right)}.$$

Hence R is the same for all points on any ellipse which is similar to the boundary of the section.

4. In general U is given by

$$-2U = \tfrac{1}{2} c^2 \iint \log r^2 . (\cosh 2u - \cos 2\theta) \rho \, du \, d\theta.$$

If $\rho (\cosh 2u - \cos 2\theta)$ = constant = k, suppose, then we get

(i.) $\lambda < v$, or P outside the cylinder,

$$U = \pi k c^2 (\lambda - \mu) \log \frac{2}{\alpha + \beta}.$$

But if M be the quantity of matter in unit length of the cylinder, $M = \pi k c^2 (\lambda - \mu)$. Hence $U = M \log \frac{2}{\alpha + \beta}$, and the equipotential surfaces are confocal cylinders.

(ii.) P in the space surrounded by the matter—that is, $v < \mu$.

$$U = \tfrac{1}{2} M \left(\log \frac{2}{a+b} + \log \frac{2}{a'+b'} \right)$$
= constant.

(iii.) P in the attracting matter—that is, $\lambda > v > \mu$.

If M_1 be the quantity of matter between the cylinders μ and v, M_2 that between v and λ, so that $M_1 + M_2 = M$, then

$$U = M_1 \log \frac{2}{\alpha+\beta} + \tfrac{1}{2} M_2 \left\{ \log \frac{2}{\alpha+\beta} + \log \frac{2}{a+b} \right\}$$

$$= \pi k c^2 (v - \mu) \log \frac{2}{\alpha+\beta} + \tfrac{1}{2} \pi k c^2 (\lambda - v) \left\{ \log \frac{2}{\alpha+\beta} + \log \frac{2}{a+b} \right\}.$$

As in case (i.), the equipotential surfaces are confocal cylinders.

If p be the perpendicular from the centre of the ellipse, u, on the tangent at the point θ, then $(\cosh 2u - \cos 2\theta) p^2 = 2 c^2 \cosh^2 u \sinh^2 u$, and therefore $\rho = k p^2 / 2 c^2 \cosh^2 u \sinh^2 u$.

More generally if $\rho = p^2 . f(u)$, where $f(u)$ is a function of u only, it is clear that the equipotential surfaces will be confocal cylinders when the attracted point is outside or in the matter of the attracting cylinder, and U will be constant when the point is in the space surrounded by the matter.

5. If ρ be a function of u only—that is, if the matter be arranged in confocal layers—the discussion is simple.

$$-2U = \tfrac{1}{2} c^2 \int_\mu^\lambda f(u) du \int_0^{2\pi} \log r^2 (\cosh 2u - \cos 2\theta) \, d\theta.$$

Hence

(i.) $v > \lambda$.

$$-2U = 2\pi c^2 \left(v + \log \frac{c}{2} \right) \int_\mu^\lambda f(u) \cosh 2u \, du$$
$$+ \pi c^2 e^{-2v} \cos 2\phi \int_\mu^\lambda f(u) \cosh 2u \, du;$$

or, $$U = M \log \frac{2}{\alpha + \beta} - \tfrac{1}{2} M e^{-2v} \cos 2\phi;$$

so that when $v > \lambda$, U is of same form as when ρ is constant.

(ii.) $v < \mu$.

$-2U = 2\pi c^2 \int_\mu^\lambda \left(u + \log \frac{c}{2} \right) f(u) \cosh 2u \, du + \pi c^2 \cosh 2v \cos 2\phi \int_\mu^\lambda e^{-2u} f(u) \, du$ so that U has the form $C + D \cosh 2v \cos 2\phi$, or $C^1 + D^1 (x^2 - y^2)$ where C, D, C^1, D^1 are independent of v, ϕ or x, y—the same form as when ρ is constant.

(iii.) $\lambda > v > \mu$.

$-2U = 2\pi c^2 (v + \log \frac{c}{2} + \tfrac{1}{2} e^{-2v} \cos 2\phi) \int_\mu^v f(u) \cosh 2u \, du + 2\pi c^2 \int_v^\lambda \left(u + \log \frac{c}{2} \right) f(u) \cosh 2u \, du + \pi c^2 \cosh 2v \cos 2\phi \int_v^\lambda e^{-2u} f(u) \, du.$

In case (i.) the attractions are $X = \frac{4M}{c} e^{-v} \cos \phi$, $Y = \frac{4M}{c} e^{-v} \sin \phi$.

In case (ii.) the attractions are $X = 2 D' x$, $Y = -2 D' y$.

6. In the general case when ρ is a function of u and θ, we suppose the function F (u, θ) expanded in a series of sines and cosines of multiples of θ, the coefficients being functions of u. Then since

$$\int_0^{2\pi} \log r^2 . {\sin \atop \cos} m\theta . d\theta = -\frac{4\pi}{m} {\sin \atop \cos} m\phi . {\sinh \atop \cosh} m v . e^{-mu} \quad u > v$$

$$= -\frac{4\pi}{m} {\sin \atop \cos} m\phi \, {\sinh \atop \cosh} m u e^{-mv} \quad u < v$$

the value of the potential can be expressed in a series involving integrals with respect to u only.

If $\rho = \Sigma\, A_n \cos n\,\theta + \Sigma\, B_n \sin n\,\theta$, then it is easily seen by considering the integral which defines U or otherwise, that

$$U = C_o \log \frac{2}{a+\beta} + \sum_{n=1}^{\infty} e^{-nv}(C_n \cos n\phi + D_n \sin n\phi)\, v > \lambda$$

$$U = E_o + \sum_{n=1}^{\infty} (E_n \cosh n\,v \cos n\,\phi + F_n \sinh n\,v \sin n\,\phi)\, v < \mu$$

If $\lambda > v > \mu$, U will be given by integrals which have v as one of the limits, since in that case

$$\int_\mu^\lambda f(u)\,du \int_0^{2\pi} \log r^2 . \cos n\,\theta\, d\theta = \int_\mu^v f(u)du \int_0^{2\pi} \log r^2 . \cos n\,\theta\, d\,\theta$$
$$+ \int_v^\lambda f(u)du \int_0^{2\pi} \log r^2 \cos n\theta d\,\theta,$$

and the integral with respect to θ has a different value in the two cases.

In special cases the complete solution is easily found; for example, when $\rho = Ax + By + C$, or $Ax^2 + Bxy + Cy^2 + D$, and so on; or when $\rho = k\,.f^{2n}$, where f is the distance of (u, θ) from the origin, since $f^2 = \frac{1}{2}\, c^2 (\cosh 2\, u + \cos\, 2\,\theta)$.

7. If the inner boundary of the cylinder is a similar and coaxal ellipse, the integrals are usually more complicated than when it is a confocal ellipse. We may now put $x' = m\, a \cos\,\theta$, $y' = m\, b \sin\,\theta$, and the outer boundary will be determined by $m = 1$, the inner by $m = m' = a'/a = b'/b$.

$$-2\,U = a\,b \int_{m'}^1 m\,d\,m \int_0^{2\pi} \log\{(x - m\,a\cos\,\theta)^2 + (y - m\,b \sin\,\theta)^2\}\,\rho\, d\,\theta.$$

If (x, y) be in the space surrounded by the matter, and if ρ be constant, we have, since the integral with respect to θ is $4\,\pi \log \frac{m\,a + m\,b}{2}$,

$$U = \pi\,\rho\, a\, b \log \frac{2}{a+b} - \pi\,\rho\, a'\, b' \log \frac{2}{a'+b'} + \tfrac{1}{2}\,\pi\,\rho(ab - a'\,b') = \text{constant.}$$

In this case, therefore, the attraction is zero.

If (x, y) be outside, and if we suppose the shell to be infinitely thin, we find

$$U = 2\,\pi\,\rho\, a\, b\, m\; d\,m\; \log \frac{2}{a+\beta} = M \;\log \frac{2}{a+\beta};$$

where M is the mass of unit length of the shell, and a, β the semi-axes of the confocal through (x, y).

The integration with respect to m for a cylinder of finite thickness, though quite easy, is rather complicated in its final expression; but if we suppose $m' = 0$ so that the cylinder is complete, we get as in §1

$$U = \pi\,\rho\, a\, b \log \frac{2}{a+\beta} - \tfrac{1}{2}\,\pi\,\rho\, a\, b\, e^{-2v} \cos 2\,\phi.$$

In the case where m' is not zero the expression involves also confocals with respect to the inner boundary.

If ρ is not constant the integrations are usually complicated, but it is obvious that if the matter be arranged in strata bounded by similar elliptic cylinders there will be no attraction at an internal point though the density be different in different strata. These conclusions are easily deduced by the usual geometrical method.

8. In dealing with surface distributions on an elliptic cylinder it is, perhaps, simplest to write $d\,s = J^{-1} . d\,\theta = (a\,b/p)\, d\,\theta$, where $d\,s$ is an elementary arc of the ellipse λ, and p is the perpendicular on the tangent at θ. If σ be the surface density, then

$$-2\,U = a\,b \int_0^{2\pi} \frac{\sigma}{p} \log r^2 . d\,\theta.$$

If $\sigma = k\,p$, then the mass on unit length of the cylinder is M where $M = 2\,\pi\, a\, b\, k$. Hence

$$U = M \log \frac{2}{a+\beta}\; v > \lambda.$$

$$U = M \log \frac{2}{a+b}\; v < \lambda.$$

It may be noticed that since $\sigma = M\; p/2\,\pi\, a\, b$, we get, when we express σ in terms of λ and θ,

$$\sigma = \frac{M}{2\,\pi\, c}\left(\frac{2}{\cosh 2\,\lambda - \cos 2\,\theta}\right)^{\frac{1}{2}}.$$

Hence, if $\lambda = 0$—that is, if the cylinder becomes a plane of breadth, $2\,c$,

$$\sigma = \frac{M}{2\,\pi\, c \sin\,\theta} = \frac{M}{2\,\pi\, \sqrt{c^2 - x^2}}.$$

The potential is, of course, $U = M \log \frac{2}{a+\beta}$.

More generally if σ be of the form $p\,f\,(\theta)$, and if $f\,(\theta)$ be put in form

$$f\,(\theta) = A_o + \sum_1^{\infty} (A_n \cos n\,\theta + B_n \sin n\,\theta),$$

we get, if v be greater than λ,

$$U = 2\,\pi\, a\, b\, \Big\{ A_o \log \frac{2}{a+\beta} + \sum_1^{\infty} \frac{e^{-nv}}{n}$$
$$(A_n \cosh n\,\lambda \cos n\,\phi + B_n \sinh n\,\lambda \sin n\,\phi \Big\}$$

and if v be less than λ

$$U = 2\,\pi\, a\, b\, \Big\{ A_o \log \frac{2}{a+b} + \sum_1^{\infty} \frac{e^{-n\lambda}}{n}$$
$$(A_n \cosh n\,v \cos n\,\phi + B_n \sinh n\,v \sin n\,\phi \Big\}$$

9. Since when $\sigma = M\; p/2\,\pi\, a\, b$, the potential of the cylinder is constant, we get for the electric potential of an elliptic cylinder, on which there is a charge M per unit of length

$$V = 2\,M \log \frac{2}{a+b},$$

and the capacity per unit of length is $1/2 \log \frac{2}{a+b}$, reducing to $1/2 \log \frac{1}{r}$ when the cylinder is circular.

If there be two confocal cylinders, the potential and the capacity are most readily deduced from Laplace's equation, expressed with v, ϕ as variables. Obviously, $V = C_1 - C_1 v = C + D \log\, (a + \beta)$ satisfies that equation, and if the outer be at potential A, the inner at potential B,

$$V = \frac{A \log \frac{a+\beta}{a'+b'} + B \log \frac{a+b}{a+\beta}}{\log \frac{a+b}{a'+b'}}.$$

The surface densities will be given by

$$4\,\pi\,\sigma_\mu = \frac{B - A}{\log \frac{a+b}{a'+b'}} \cdot \frac{p'}{a'\,b'};\; 4\pi\sigma_\lambda = \frac{A - B}{\log \frac{a+b}{a'+b'}} \cdot \frac{p}{a\,b}$$

and the charges per unit length

$$E_\mu = \frac{B - A}{2 \log \frac{a+b}{a'+b'}} = -\,E_\lambda;$$

so that the capacity of the inner cylinder is $1/2 \log \frac{a+b}{a'+b'}$.

10. With regard to the equipotential surfaces that are given by the different expressions for U, it may be noted that when the point is outside the cylinder these are either confocal cylinders, or cylinders that at a distance from the attracting matter approximate to confocals. For example consider the case

$$-\,U = M \log \frac{a+\beta}{2} + \tfrac{1}{2}\, M\, e^{-2v} \cos 2\,\phi$$

When v is large, $-\,U = M \log \frac{a+\beta}{2}$ approximately, so that the equipotential surface is a confocal cylinder. Further,

$$\frac{d\,v}{d\,\phi} = \frac{\sin 2\,\phi}{e^{2v} - \cos 2\,\phi},$$

so that v increases with ϕ as ϕ goes from 0 to $\pi/2$. Further,

the curve of section is symmetrical with respect to both axes, so that only values of ϕ between 0 and $\pi/2$ may be considered in tracing the curve. If we put $(M \log \frac{c}{2} + U)/M$ equal to $-f$, the curve will be given by

$$v = f - \tfrac{1}{2} e^{-2v} \cos 2\phi;$$

when $\phi = \pi/4$, $v = f$; when $\phi < \pi/4$, $v < f$; when $\phi > \pi/4$, $v > f$. The curve, therefore, interlaces the ellipse $v = f$, lying within this ellipse when ϕ is between $-\pi/4$ and $\pi/4$, or $3\pi/4$ and $5\pi/4$, and lying outside it in the other cases. It is clearly normal to the axes where it crosses them, and is everywhere concave to the axis of x. A rough tracing of the curve can readily be made from these data.

Again, $v = f - \frac{1}{2} e^{-4v} \cos 4\phi$ would intersect the ellipse $v = f$ in eight points, and so on.

Cases of the form $U = A + B \cosh 3v \cos 2\phi$ are easily discussed; for $\cosh 2v \cos 2\phi = 2(x^2 - y^2)/c^2 - 1$; and $\cosh 3v \cos 3\phi$, $\sinh 3v \sin 3\phi$, etc., can also be expressed rationally in terms of x and y.

INSTITUTION OF ELECTRICAL ENGINEERS.

EXPERIMENTAL RESEARCHES ON ALTERNATE-CURRENT TRANSFORMERS.

BY J. A. FLEMING, D.SC., F.R.S., MEMBER.

(Concluded from page 456.)

We found it essential to standardise the wattmeter on the largest power absorbing arrangement possible, so as to get the greatest possible wattmeter scale reading on a known power absorption in determining the instrumental constant. For if a small power reading was taken, then any error in the scale reading was multiplied up in getting the watts corresponding to a larger scale reading taken from a value of the constant, and sensible errors introduced.

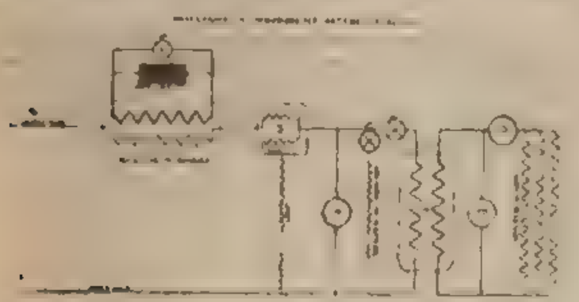

FIG. 4.

In addition to this instrument Mr. Swinburne provided two of his own non-inductive wattmeters. In this last instrument the shunt circuit consisted of a small bobbin of a good many (probably a hundred or more) turns of fine wire, having a resistance of about 300 ohms. In series with this externally, and forming part of the wattmeter shunt circuit, were two doubly wound wire resistances in brass boxes, having a total resistance of about 100 000 ohms, assumed to be practically non-inductive. Provided with these wattmeters, we proceeded to make a series of tests on various transformers of the power absorbed when the transformer was doing secondary work of various loads.

In the tests the transformer had gradually increasing loads of lamps put upon its secondary circuit and whilst the power, W_1, supplied to the primary was measured by the dynamometer wattmeter, that given up by the secondary, W_2, was measured by a Kelvin balance and electrostatic voltmeter placed on the secondary circuit. We measured also the primary current value in amperes corresponding to each definite load on the secondary circuit. We obtained, therefore, for every transformer, the volts, or P.D. across both terminals, the ampere current, and the watt output of the secondary circuit, and at the same time the ampere current and power absorbed in watts by the primary circuit; and hence the difference between W_1 and W_2, or the power lost in the transformer, is also known for each secondary load. Finally, also, the ratio of W_2 to W_1 in percentages can be calculated, and gives us the efficiency. In all these experiments the P.D. on the primary terminals was kept carefully constant at 2,400 volts, and the constant of the primary wattmeter checked at the beginning and end of each series of observations.

A series of tests of this kind was made on each one of the following 10 transformers: A Ferranti 5 h.p. (1885 type), a Ferranti 5 h.p. after having had the primary and secondary circuits both replaced by others of double the length, two 15 h.p. (1892 type) Ferranti, a 20 h.p. (1892 type) Ferranti, a Westinghouse 6,500-watt (the same transformer used by Dr. Hopkinson in his recent tests), a Mordey Brush 6,000-watt, a Thomson-Houston 4,500-watt, a Kapp 4,000-watt, and a Swinburne 3,000-watt "Hedgehog." For each transformer was determined the currents and terminal potential differences corresponding to the various stages of secondary load from no load up to the full nominal output of the transformer, and at the same time the power, W_1, given to the transformer primary circuit, and the power, W_2, taken off from the secondary circuit. The "total lost watts," $W_1 - W_2$, and the efficiency, or ratio, $\frac{W_2}{W_1}$, corresponding to each secondary load, were also calculated. From the known or measured value of the resistances of the copper circuits taken when the transformer was warm and the measured currents we could calculate the copper losses (C^2R losses) in both circuits, separately and together, to the nearest integer, omitting fractions of a watt in most cases; and from the primary volts and current we obtained the value of the "apparent watts" given to the transformer at each stage; and from the "apparent" and "true" watts given to the primary circuit we could deduce the power factor corresponding to any secondary output. The values of the secondary terminal P.D., or volts, gave us also the "total secondary drop" at each load, and from the resistances and currents could be found the "copper drop," or volts lost by resistance. The observations and calculations for each of the 10 transformers tested are given in full in a series of tables.

The results of these numerous observations are set out graphically, and thus represented to the eye, in a series of diagrams. For each transformer four diagrams have been prepared. [We give only a selection of the whole.—ED. *E. E.*]

The first shows the "total lost watts" curve, or $W_1 - W_2$, plotted as a curve in terms of the corresponding secondary output W_2; and on the same diagram is given a curve showing the total copper losses (C^2R) in the transformer in both circuits together. Hence the difference of the ordinates of those two curves gives the value of the losses other than those due to ohmic resistance in the transformer. The second diagram shows the value of the two currents, primary and secondary, plotted in terms of the secondary output. Since all the closed magnetic circuit transformers tested had a transformation ratio and windings in the ratio of 24 to 1, the primary current and $\frac{1}{24}$th part of the secondary current are plotted together on the same scale. The third diagram gives the efficiency curve. The efficiencies in per cents., corresponding to decimal fractions of the full secondary output, are calculated from the "total loss" curve and then drawn. Hence they are all comparable, and we can see at a glance the percentage efficiency corresponding to loads of $\frac{1}{10}$th, $\frac{2}{10}$ths, etc., of the full secondary load. The fourth curve is the "secondary drop" curve, and gives the "total observed drop," the "drop" due to secondary and to primary resistance, and the surplus or "leakage drop," due to leakage of induction, all plotted in terms of the secondary output. The efficiency values are tabulated in Table XXX. for the different fractions of full load for all the transformers.

It is desirable to make one or two remarks about each transformer, and draw some general conclusions. [We only give a portion of these remarks.]

Ferranti Transformers, 1892 Type, 15 and 20 h.p.—These new transformers of Mr. Ferranti's are exceedingly good transformers. The total loss on open circuit of the 20 h.p. is only 1·3 per cent. of the full secondary output. The maximum efficiency is 97·1 per cent., and the efficiency at one-tenth of full load is 85 per cent., whilst the total secondary drop is only 2·1 per cent.

Westinghouse Transformer, 6,500 Watt.—This transformer was one of the pair tested by Dr. J. Hopkinson by his elegant differential method. His results are recorded in the *Electrical Engineer* of July 1, 1892. Dr. Hopkinson's results are placed in the column marked H, those of the manufacturers in column P, and my own in column F; and it will be seen that we all substantially agree in the values of the quantities measured.

Quantities measured.	P.	H.	F.
Watts lost at no load	91	111	98
Watts lost at half load	–	149	141
Watts lost at full load		236	209
Secondary drop at full load	2%	2·2%	2·4%
Efficiency at half load	96·4%	96%	96%
Efficiency at full load	97%	96·9%	96·9%
Total copper losses (C^2R) at full load, in watts	104	—	93

The maximum efficiency is just upon 97 per cent., and its efficiency at one-tenth of full load is nearly 85 per cent.

Mordey Transformer, 6,000 Watt.—Two transformers of this size were tested. In one the three-voltmeter method showed the power loss at no load to be 125 watts; in the other, the dynamometer wattmeter gave 148 watts. If we take the mean of these results, we get 136 watts as the open circuit loss. This is 2·27 per cent. of 6,000 watts. According to our observations, this transformer takes rank as one of the best for regulation, having regard to its size and its open circuit loss.

Kapp 4,000 Watt Transformer.—This is a very interesting transformer, having an exceedingly good regulation for such a small size. Its total secondary drop is under 2 per cent. of its secondary voltage at no load, and its open circuit loss is 2·8 per cent. of full output. It is curious in the rather slow rise of its power factor as

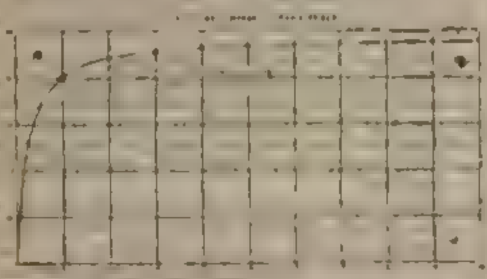
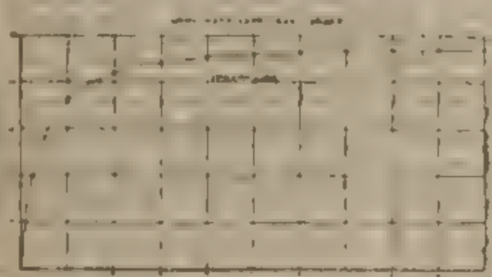
the secondary load is increased. The good regulation of the transformer and small "leakage drop" are no doubt due to the effective "sandwiching" of the primary and secondary coils.



Efficiency Curve—6,000-Watt Mordey Transformer.



Efficiency Curve—4,000-Watt Kapp Transformer.

Swinburne 3,000 Watt "Hedgehog" Transformer. Lastly, but by no means least, there are several remarks to make about the "Hedgehog" transformer of Mr. Swinburne. The mean of all means of over 62 observations by three different methods gives the value of 112 watts for the power absorbed at no load in this 3,000 watt "Hedgehog" transformer.

GENERAL REMARKS ON THE ABOVE EXPERIMENTS.

On examining all those diagrams in which are delineated the curves of total loss of power in the transformer and the curve of total copper resistance loss, C^2R, it is found that in every case the upper curves are *sensibly parallel*. In the curves for closed magnetic circuit transformers of good design the difference between the total C^2R loss and the total loss of all kinds is the iron core loss in the transformer. Hence we see that all the experiments lead to the conclusion that *the iron core losses are constant at all loads*. In no case have we found any substantial evidence that the iron core losses are evanescent at full secondary load. This last view has been held by Mr. Mordey and others. Seeing that our methods, when applied to the 6,000 watt Mordey transformer, give practically the same results at no load as Mr. Mordey obtains, it is an interesting matter to enquire how it comes to pass that the calorimetric method employed by him seemed to indicate that the whole loss in the transformer at full load was accounted for by the frictional losses in the copper. At present the writer can offer no explanation of this discrepancy. The above-described observations were all made and plotted out before the appearance of the paper of Prof. Ayrton and Dr. Sumpner, and shown to many people, but it is very satisfactory to find that their undoubtedly excellent method has conducted them to precisely the same conclusion. Hence we seem to have very good reason to believe that the total internal loss curve of a transformer can be drawn from observations of the C^2R losses and the total core loss at no load.

When we come to consider it, it is very difficult to see on what valid supposition we could conclude that hysteresis loss should be less at full than at no load. The only difference in the magnetic conditions are that in one case the iron is magnetised by a small current acting in one direction, and in the other by the difference between two currents flowing in opposite directions, but governed by the condition that the total ampere turns remain the same. In a special experiment I have taken the hysteresis diagram for a soft iron wire employing a magnetising force of 1,000 ampere turns, in one case produced by 2·5 amperes and 400 turns, and in the other case by 20 amperes and 50 turns. The hysteresis areas for a complete cycle were found to be practically the same—the [illegible] if anything, the larger of the two. Prof. Ewing's direct [illegible] on this point will be remembered.

These measurements have brought out, in addition, another very interesting fact. In the tables for each transformer is given a column of figures headed "Power factor." We have already defined this term as the ratio of the "true watts" to the [illegible]ent watts," or product of the effective amperes and effective volts. This ratio is given for each measurement of the power. We see at once that for closed magnetic circuit transformers of good type, such as the Mordey, Westinghouse, Ferranti, etc., the power factor at no secondary load begins at a value of about 0·8 or thereabouts. For such types of transformers, however, a very little loading up of the secondary circuit—not more than one-tenth of full load—brings the power factor up to unity. For an open magnetic circuit transformer like the "Hedgehog" the case is quite different. The P.F. begins at a value of 0·08 or 0·06, and it never rises up above 0·8. Hence at no stage of the load is the real power taken up by the transformer anywhere nearly equal to the "apparent watts." A transformer like the 4,000 watt Kapp appears to occupy an intermediate position, and although it has a medium power factor to start with, its P.F. rises up to unity at about half load. The importance of this fact in alternate-current station working is very great. It shows us, if we have a station wholly supplied with transformers of the type of Mordey, Westinghouse, Thomson Houston, Ferranti, etc., that the apparent watts supplied to the transformers is the real watts at any hour when all the transformers are more than one-tenth loaded. If, however, the station is engineered with "Hedgehogs," or with that museum of transformers of all sorts and makes which some central station engineers are fond of gathering together under the idea, perhaps, that they can "hedge" for economy and make up for the vices of one kind by the virtues of another, then in hardly any state of the load will it be safe to assume the identity of the true and apparent measures of outgoing power. We must, of course, here assume that concentric primary cables are not in use, otherwise an error of another kind may be introduced. If we take the case of a station provided wholly with closed magnetic circuit transformers, and consider it as having an average kind of load diagram, say for the whole year, then if the measure of the "apparent units" sent out from the station is taken, I do not think that in general we shall be far out in our estimate of the true units sent out if we deduct from the apparent units about 12 to 15 per cent. and call the remainder the measure of the true units of energy sent out in the whole time.

[A large part of the paper here was concerned with the incorrectness of a Swinburne wattmeter, which the author suggested had led Mr. Swinburne to wrong conclusions as to the value of the Hedgehog transformer.]

CONCLUSION.

There are very many derivative matters which, if space permitted, might be discussed as consequences of facts observed in the course of the above-described researches. It is evident, for instance, that the last word has by no means been said on the subject of design of transformers. I have every hope that before long transformer manufacturers may be able to produce transformers of 25 h.p. and upwards having close upon 90 per cent. efficiency at one-tenth of full load. When that is done, it will be interesting to repeat some of those calculations which have already been made as to the relative cost of delivering a certain [illegible] of thousand units on an average load diagram, say for distances of 1,000, 2,000, 3,000 yards, etc., by low pressure feeders and by high pressure plus transformer feeders. [illegible] can be made with some degree of confidence now that it [illegible] clear that the iron losses in transformers are constant at all loads, and that there is a definite relation between this loss and the open circuit or magnetising current. We can hardly regard the great controversy of open versus closed magnetic circuits as entirely and definitely settled, but there is no reason to believe that the majority of those who have designed transformers with closed magnetic circuits have been supremely unwise in their faith or in their work.

In the matter of transformer testing the experience gained in obtaining the facts brought before you has established in the writer's mind at least the feeling that a properly constructed dynamometer wattmeter is perhaps the best workshop instrument

to use for this purpose, but that its personal character must be strictly examined before trusting too implicitly to the results obtained by it.

In conclusion it will only be right to make mention of those who have assisted me in the somewhat arduous work of taking the observations here recorded. The principal share of this has been borne by my assistant, Mr Shields who has worked with great perseverance and care for many months in taking the actual observations, and this in many cases required some painstaking work. He was assisted at intervals by Messrs J. and D. Morris, students in University College, London, especially in those observations in which the careful simultaneous reading of several instruments was required. The observations on the sudden rush of current into transformers were made for me by Mr. Wordingham.

The facts and measurements thus obtained have in all cases been sifted and repeated with the greatest possible care, with the desire to arrive at conclusions which should be worthy of confidence, and useful to those engaged in transformer manufacture and design.

INSTITUTION MEETING, December 1.

The formal business of reading the minutes was duly carried out, and the following gentlemen were balloted for and elected:

Members.—William D. Hunter, Newcastle and District Electric Lighting Company, Newcastle on Tyne; William Johnson, Sheffield Electric Light and Power Company, Sheffield.

Associates.—J. W. Chisholm, Central Electric Lighting Station, Whitehall road, Leeds; Captain Thomas Harrison, R.E., Burmah.

The discussion on Dr. Fleming's paper was then commenced by **Mr Swinburne**, who referred in the first place to the electrostatic voltmeter and its damping arrangements, stating that they had tried oil damping but preferred the electromagnetic; and also to the sparking of the voltmeters, explaining that the voltmeter used was designed for 1,200 volts, and was tried with 2,500. He did not like mica because it introduced difficulties in calibration. Turning to the wattmeter the speaker had for at least five years suggested the use of the wattmeter, but the professors had objected to it because of its simplicity. Nothing mattered to the Professor if it were sufficiently complicated. In the paper it was inferred that his wattmeter was educated up to read experiments on the Hedgehog. The speaker explained how it came to pass that this particular wattmeter was wrong. He found that capacity did not cause the error in the wattmeter. Dr. Fleming's suggestions were not correct, but the real error was due to Foucault currents in the brass case, and the speaker explained this by means of a diagram. Coming now to the important part of Dr. Fleming's paper, the speaker agreed as to the value of the wattmeter for testing purposes. The next point definitely settled was they could calculate efficiency at full load, in that the loss in the iron was constant, or nearly so. A third point unsettled was the value of the open compared with the closed circuit transformers. The speaker agreed that the particular transformer sent to Dr. Fleming and tested by him was not a good one. As regarded the eddy currents in the copper, these were first investigated by Sir W. Thomson, and after this investigation Mr. Swinburne had made a table and used wire that ought not to have had eddy currents. He had tried removing the secondary circuits and found no difference; he removed the phosphor bronze and the ends and found no difference. Recently, however, he thought they had found the point of difficulty, in the Foucault currents in the core. He protested against the use of power factors for all transformers, as it would lead to error, but agreed with the importance of cost and weight. He referred to a paper relating to the drop of a transformer which appeared in *Industries*, and if that were correct then Dr. Fleming's argument was altogether wrong. He found that condensers broke down in switching off rather than in switching on, and he thought the reason was due to a kind of arcing effect, and not that given by Dr. Fleming. In conclusion, the speaker called attention to a station wattmeter exhibited to the meeting.

Prof Forbes agreed as to the value of the paper, if only in teaching Mr. Swinburne to make an accurate wattmeter and a good transformer. Hitherto people thought all transformers had somewhat the same efficiency. Dr. Fleming's experiments had corroborated his own experiments with the Westinghouse transformer. Great attention had justly been paid to making transformers efficient at light loads, but the future might give rise to sub-stations and larger transformers, when the great efficiency at low loads would not be of such great importance. Efficiency at different loads meant designing the proper proportion of copper and iron for the particular load where efficiency was required. Somewhat the same held good when power was transmitted from a water motor; the efficiency was required at full load and not so much at low load. He had found that at Niagara the cost of transformers with much copper would be more than that of the dynamos, with less copper and lower efficiency at low loads, the cost was half or one third only.

Mr Kapp thought the paper of Dr. Fleming of unique interest. He had the more confidence in that the figures were evidently in no way cooked, 100.1 per cent. being given as the result of one experiment though impossible. He looked upon the paper as an absolutely reliable record of the present state of transformer practice. Dr. Fleming had used the wattmeter system, and although this system had been used at Frankfort with standardised instruments, he preferred the voltmeter method. He took three readings with the same voltmeter, using mercury contact changes, and found that by taking four sets he obtained very consistent results. Since the publication of Dr. Fleming's paper he had himself made tests to see the effect of the heavy copper core, taking one transformer with a thick copper winding, and another with exactly similar core wound with thin wire. He found that the loss was with the thick wire 120 watts, including hysteresis, and with thin 130 watts, so that there was no great difference from the cause. The researches of Dr. Fleming would be of the greatest utility in enabling engineers to decide upon the relative value of direct and transformer systems. Until now they had been working in the dark, assuming a low efficiency at one-twentieth load. Now it is found that it is possible to get transformers with 75 per cent. efficiency at one-twentieth load, and 85 per cent. at one-tenth load. The load at central stations never sunk below one-twentieth, and this lowest load tends to improve. Even at lightest loads, therefore, transformers give 80 per cent., and at heaviest load 96 per cent.—a high average over the whole. But in the direct current system, where the feeders lose 20 per cent. at heaviest load, the loss is evidently greatest at the time of highest load, whereas with transformers the greatest loss is with the light load. Engineers would work with more confidence after this paper by Dr. Fleming.

The **President** asked Mr. Kapp whether in his test of the transformer, the transformer was closed or open magnetic circuit, whether the fine wire were inside or out, and whether he magnetised the inner or outer core, and whether he transformed up or down.

Mr Kapp replied it was with closed magnetic circuit, thick copper, next the core, thin outside, pressure 100 volts. The same carcase was used with thin wire in the same position as thick wire. The transformer was of the Brown Boveri type, transforming up.

The **President** said the conditions, therefore, were not the same, as if he had tried transforming down. He would deal with this point in his remarks.

Mr Evershed thought that before the discussion on this admirable paper closed attention should be given to the history of the investigations into the theory of transformers. Passing by the theories of the early constructors, he directed attention to the labours of Prof. Ryan in America, whose paper, he contended, really solved most, if not all, the problems connected with transformers. That paper received very little attention here. Mr. Mordey's well known experiments, which were in direct opposition to those of Prof. Ferraris, were also referred to, and the speaker hinted that probably Mr. Mordey had by this time begun to think his view of the case might be wrong. The speaker had at the time as had some others, combatted the views of Mr. Mordey, but found that Prof. Ayrton also agreed with Mr. Mordey, and accepted the results of his students' investigations as correct. Hence he thought he might be wrong, though it seemed to him that Prof. Ayrton's conclusions were contrary to nature's laws. Then came Mr. Swinburne's paper on the design of transformers, which was carefully studied in America, and this paper together with that of Prof. Ryan, led the Americans to do better with transformers than in this country, and he was glad to find an American transformer coming out at the top of the tree in Prof. Fleming's experiments, and felt it was only just what they deserved. He referred to his own experiments in collaboration with Mr. Vignoles, the results of which were in accordance with those of Prof. J. Hopkinson, but it was not till the publication of Dr. Hopkinson's results that the professors began to be converted, and he assured them that there was more joy in that Institution over one professor that repented, than over ninety and nine who continued in the way of error.

Mr. W. B. Sayers sent a communication, pointing out that as with a conductor, where alternate currents were used, the magnetic circuit was not affected to the same depth. The centre of the metal was not magnetised to the same extent as the outer, and the skin might even be opposite by reason of the eddy currents.

Mr Evershed said this matter had been fully gone into by Mr. Swinburne and himself, and they had found that the effect was very small. In extreme cases the induction in the centre of the iron magnet might be 2 per cent. less than outside.

The **President** then stated that the further discussion on Dr. Fleming's paper would be adjourned to the meeting next Thursday, and that Sir D. Salomons would explain a new machine which was exhibited on the table.

Sir D Salomons then explained that his work was the outcome of Mr. Tesla's investigations. He was sorry he could not show the machine in action, but he thought it right to show it first to the Institution. They must take his word for it that it had worked. The machine was for the purpose of producing alternating currents of very high frequency from ordinary direct currents. It had been made by Mr. Pyke, of Pyke and Harris, who had given much attention to the question of high frequency currents. It consists of two discs, whose outer rings are slotted into 360 slots, the magnetism in one side of the machine producing induction in the other. The diameter is only 1ft., so that to give sufficient alternations it had been made so that both rings revolved at 1,500, so that the passing speed was 3,000 revolutions. This, by 360, gave over a million revolutions per minute, if every alternation acted, as he has every reason to suppose was the case. They had given it the name of "directo alternating current transformer." The interior of one side formed the fields of an ordinary motor, and the other a Gramme ring. Sending current in, made them revolve in opposite directions. The current used was ½ ampere at 200 volts, and he had certainly got up to over 100,000 volts. This he had taken without unpleasant effect through the body, and lighted vacuum tubes thereby.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence: Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,

LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free. Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With this issue of the Paper is given a Supplement containing Portraits, taken from photographs, of **Mr. Magnus Volk, Mr. Chas. Capito, Mr. Henry F. Joel, Mr. F. M. Newton,** and **Mr. George Offor.**

Every reader should see that he gets this Supplement, and non-delivery with the Paper should be reported at the Publishing Office.

THE INSTITUTION BALLOTING LIST.

In another column will be found the Institution's Council list of those names suggested for official positions during the forthcoming year. On several previous occasions it has been our good or bad fortune to have given publicity to adverse criticisms on the tactical management of the Institution. It will be remembered that some years ago, owing to the expression of opinions from outside members, the Council adopted the plan of giving alternative names. In many respects this was a better plan than the present, but was found to have insuperable objections, due principally to "human nature." An examination of the matter soon shows how great the difficulty. Gentlemen are approached by the Council to ascertain if they will serve if elected. Now, if six gentlemen are nominated from the Council and only three can be elected, three have to stand out in the cold—it may be with a very few votes to their names. Such a position is an unpalatable one, and not desired by the majority of people. It may, and often is, taken to mean that, in the eyes of the Council, who should have a good opportunity of knowing eligible parties, a man is considered eligible who, in the estimation of the majority of members, is only fit to be placed at the bottom of the list. If human nature was not such a huge factor with members of the Council as well as with ordinary members of the Institution, the selection of eligible candidates by the Council would be the best possible way of ensuring a competent Council. Unfortunately, however, there is too great a tendency to form a ring rather than to ensure due, and not undue, representation of every branch of the profession. The welfare and reputation of the Institution is, if not lost sight of, relegated to the background in the effort to ensure the continuation of ruling as it exists. And yet everyone who considers the question will agree that continuity of action is a necessity, and no one would wish to upset a Council which conducted the business fairly well by new brooms that wanted to change everything. We have not the slightest doubt but that the Council are fully alive to the difficulty of pleasing everybody, and we take it as a sign of strength rather than of weakness that they say, These are the men you ought to elect, rather than leaving selection to a working clique or the haphazard selection of a lucky-bag. The number of members who take any great interest in the selection of Council is comparatively small, and composed of two bodies—the one supporters of the existing Council, the others supporters of those who would like to be on the Council. It is unnecessary to say that membership of the Council to practical business men has a considerable value, even though that value cannot be gauged in pounds sterling; therefore ordinary members should be somewhat jealous of those submitted for their approval. The present selection of names will not, as we say, please everybody, but on the whole the support of the members should be with the action of Council. Give the officers full confidence or nothing in those matters which are of vital import.

THE SPECIALISATION OF ACCUMULATORS.

We are rapidly coming to the time when it will be considered as loose to speak about or specify an "accumulator" as it is to specify a "dynamo." The time was, and not so many years ago, when, for ordinary purposes, there was only one kind of dynamo made—the shunt Gramme ring type—and this was used for any purpose that might be required, bolstering up its incapacities with resistances or other makeshifts. Nowadays, the requirements of a situation are accurately determined, and the dynamo is specified and made—direct or alternating, shunt or compound, or over-compounded, with light fields or heavy fields, large air gap or small air gap—according to the conditions for which it is required. The same specialisation of the accumulator has not yet been achieved, but it must come. There are two entirely different ways of considering the accumulator, as we have already had occasion to point out, in that the accumulator may be considered, in any generating plant, either as belonging to the plant, the capital side of the account, or to the fuel or maintenance side. The tendency which at first was to consider the accumulator entirely as plant has lately swung over, to a very large extent, to the tendency to consider it as a factor in the maintenance account. The two points of view are distinct. They require different methods of calculation and arrangement. Both are equally necessary, and although it is evidently well to pay attention to the maintenance theory, the other must not be left too much out of account.

The two views differ more particularly in this: that, considered as plant, the accumulator should be of the utmost perfection at all points, price being to a large extent a secondary consideration. The same thing is seen with other plant—dynamos, for instance. Where power is dear, it is certainly better to buy the very best dynamo, even if considerably dearer. On the other hand, if the accumulator is to be considered as maintenance, an item to be gradually used up, of the same relation, in fact, to the output as coal itself, then cheapness, combined with a fair efficiency, is the quality required, the wearing out being calculated as part of the cost of production of the current. On the one hand, then, the accumulator is deserving of the same extent of skill of investigation and improvement which has given us the dynamo of 98 per cent. efficiency, and on the other, is subject to the same considerations which lead an engineer to select his type of coal. Requirements differ, and accumulators, therefore, must receive the same amount of specialisation that has been given to the dynamo, each occasion for their use being considered on their merits. We shall find, primarily, four different types of accumulators—portable, traction, house, and station cells. The requirements for the first are extreme lightness, with capacity for a steady discharge; the traction cells are also required to be light, but with the capacity of responding without deleterious effect to uneven and heavy discharges; the third, the house cells, are required to be of a nature not necessarily very light in weight, which can be charged regularly, will render a high efficiency at steady discharges, and will maintain their charge without local action for days or even weeks; the fourth, the station cells, also need not be light, but must be able without bad effect on the plates to respond to heavy and sudden demands to fill up the breach in case of failure of dynamo, for a few hours at a time. Now these requirements differ almost as largely as those for dynamos, and in the same way that the cost, proportions, and weight of these machines are considered beforehand and provided for by the designers and manufacturers, must the design and manufacture of secondary cells be considered. A method of perfection costing a shilling or two extra for accumulators would not, perhaps, be worth application for one type of plate, which might render the most efficient service for another. We make, therefore, a plea to both consulting engineers and manufacturers for still further efforts in the direction of the specialisation of accumulators, confident that greater attention to this point must prove of advantage to the industry at large. Qualities that militate against the use of one type of cell may certainly prove of advantage in other fields of work, and it will be of utility that the outside consumers should be aware that they can obtain cells of this or that character as accurately as they now can their dynamos.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

WHAT IS THE USE OF A SHUNT TO A GALVANOMETER?

SIR,—I am a very puzzled student, but no doubt what is mud to me is clear water enough to somebody. I wish that somebody would help to improve my mental condition in this matter. I am told that a shunt is used with certain galvanometers so that the galvanometer coils shall not get too much current—hence get heated too much ($C^2 R$). I am told that putting in a shunt or 20 shunts does not alter the current in the original conductor, providing pressure is constant. What is the shunt for—to lessen the pressure, to prevent heating, or what?—Yours, etc.,

A PLUCKED STUDENT.

ACCUMULATORS: CHEAPNESS v. EFFICIENCY.

SIR,—The letter of Mr. Frank King, in your last issue, carries internal evidence that it was written under the influence of several misapprehensions.

In the first place, I may state, on my own responsibility, that the remark of which Mr. King complains *can* be substantiated with about the same facility as it can be made. Can Mr. King state definitely that his company do *not* "favour cheapness rather than extreme efficiency"?

I can at the same time, so far as my experience goes, confirm Mr. King's remark that the E.P.S. accumulators will compare favourably, both for efficiency and durability, with any type of accumulator at present manufactured (on a large scale). I have no reason to think that the *Electrical Engineer* differs from me in this view.

This being the case, I am puzzled to understand what Mr. King can mean when he speaks of "questionable means of advertising so-called new inventions by unfair comparison with the company's goods."

Is my patented device of throwing down a slight film of gold upon the surface of a grid, intended to carry peroxide, a "*so-called* new invention"? If so, is it an old invention, or is it no invention at all? In any case, how could it possibly be compared, fairly or unfairly, with "the com-

pany's goods"? The process was devised to improve, not to compete with, pasted-grid accumulators. Of course, Mr. King has a perfect right to his own opinion respecting the practical value of this device in obviating the local action in the peroxide plate, an action involving a continuous loss of energy, and the ultimate destruction of the plate. But, as he has not tested the effect of the gilding, his opinion can scarcely be worth much.—Yours, etc.,

DESMOND G. FITZGERALD.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

VI.—OHM'S LAW AND THE ELECTRIC CIRCUIT.

(Continued from page 537.)

Calculation of Resistance.—The resistance of a conducting wire depends on three things: 1. Its length. 2. Its diameter, or cross sectional area. 3. Its specific resistance, or substance it is made of.

The resistance of a conducting path varies directly with its length, so that a conducting wire 200 yards long has exactly double the resistance of one that is 100 yards long. The resistance of a conducting path varies inversely as its cross-sectional area, or inversely as the square of its diameter (area being proportional to the square of the diameter), so that the thinner a conducting wire becomes, the greater is its resistance. A wire having an area of one square inch has one-half the resistance of a wire having an area of half a square inch, and if the size of the wires be expressed in their diameters, then a wire of ½in. diameter has four times the resistance of a wire of 1in. diameter, and a wire of 2in. diameter has a resistance of one-fourth of the resistance of the 1in. wire. The square of 1 is $1 \times 1 = 1 = d^2$, the square of $\frac{1}{2} = \frac{1}{2} \times \frac{1}{2} = \frac{1}{4} = d^2$, and the square of $2 = 2 \times 2 = 4$, and since the resistance varies inversely as the square of the diameter, we therefore have—

First wire $d = 1$in. $\therefore d^2 = 1 \therefore \frac{1}{d^2} = 1 \therefore$ ratio $= 1$

Second " $d = \frac{1}{2}$in. $\therefore d^2 = \frac{1}{4} \therefore \frac{1}{d^2} = 4 \therefore$ " $= 4$

Third " $d = 2$in. $\therefore d^2 = 4 \therefore \frac{1}{d^2} = \frac{1}{4} \therefore$ " $= \frac{1}{4}$.

The resistance of a conducting path varies directly with its "Specific resistance."

The specific resistance of a substance signifies the resistance it has compared with the resistance of some substance taken as a standard, both substances being of absolutely the same dimensions and under the same conditions, such as temperature, etc. The specified dimensions are expressed either in French or in English measures. When the former are used the specific resistance of a substance is that given by a mass having a cross-sectional area of one centimetre and a length of one centimetre; when the latter is used it is that given by a mass having a cross-sectional area of one square inch and a length of 1in., the resistance in each case being measured lengthwise. The "Relative resistance" of a substance signifies simply the resistance as compared with a standard, no matter what the dimensions are, provided they are the same for each. Respecting the relative resistances of three substances—silver, copper, and iron—it will be found that giving unit resistance to silver, the values for copper and iron will be 1·06 and 6·4, or putting silver at 100, the others will be 106 and 640. From this it is seen, that having two wires, one of copper and the other of iron, both having the same diameter and length, the resistance offered by iron wire will be six times as much as that offered by the copper wire, because $6·4 \div 1·06$ or $640 \div 106 = 6$, roughly.

The specific resistance of pure annealed silver in English measure—that is, of a mass having one square inch area and 1in. length—is about ·000000633, or $\frac{1}{1580000}$ of an ohm, therefore the resistance of a bar of silver of 1in. area and 1ft. long will be ·0000076, or $\frac{1}{131579}$ of an ohm; this is with a temperature of, say, 18deg. C., or nearly 65deg. F., which may be taken as a fair average temperature of the atmosphere in England. Knowing the relative resistance of any substance at the same temperature, its resistance could be easily calculated out per square inch foot by multiplying the resistance of a square inch-foot bar of silver by the relative resistance, the question of length and area can then be treated according to the laws previously given. The enormous high cost of silver naturally entirely prohibits its use as a conducting wire, and the next best conductor is copper, which is only a little way behind silver in question of conductivity. Although far below silver in price, copper is an expensive metal, ranging from £50 to £80 per ton, according to the state of the copper market. The capital that must be sunk in copper for feeders and distributing mains for a certain electric light station comes to a very heavy sum, sometimes one-third of the total cost, and, as may be expected, the price of the metal is bound to become more expensive as time goes on, on account of the increasing annual consumption, due to a great degree to the progress of electric work. This is assuming that no large sources are discovered.

Copper is the only metal that is used for conveying electric currents for lighting purposes, and it is used in nearly all cases for electric transmission of power and traction. There are some tram lines where silicon bronze wire instead of copper is used, but these form an exception. We will now proceed to work out a practical formula for calculating quickly and easily the resistance of a copper conductor.

The resistance of a bar of pure hard drawn copper, 1ft. long and 1in. diameter, may be taken as ·0000105, or [illegible] of an ohm. The commercial conductivity of good copper should not be under 98 per cent. of that of the pure copper, and since conductivity is the reciprocal of resistance, therefore the resistance of commercial copper should not be greater than 102 per cent. that of the pure copper. Making this correction, we find the resistance of the above bar for commercial copper will now be ·0000107, or [illegible] of an ohm. This is for a temperature of 18deg. C.

Three thousand feet or 1,000 yards of No. 13 legal standard gauge (L.S.G.) copper wire, having a diameter of ·104in., may be taken as measuring about three ohms of resistance at 18deg. C. or 65deg. F., the conductivity being 98 per cent.

To calculate the resistance of any sized copper conductor having conductivity of 98 per cent., apply the following rule. Divide the length in feet by 93,000 times the square of the diameter in inches; the quotient will give the resistance in ohms. That is,

$$\text{Ohms} = \frac{\text{Length in feet}}{(\text{diameter in inches})^2 \times 93{,}000},$$

$$\text{or, } R = \frac{L}{D^2 \times 93{,}000}.$$

When resistances are very high they are expressed in megohms, one megohm signifying one million (1,000,000) ohms.

When resistances are very low, they are expressed as microhms, one microhm signifying the one millionth part ($\frac{1}{1000000}$) of an ohm.

When currents are very small in value, they are expressed as milliamperes, one milliampere signifying the one thousandth ($\frac{1}{1000}$) part of an ampere, but this small unit is rarely used.

A few examples will now be given of applying Ohm's law, and the rules given for calculating resistances.

1. A dynamo working at 110 volts pressure at its terminals, feeds a bank of incandescent lamps having a total resistance of ·2 of an ohm; how much current do they take?

Applying Ohm's law we have $C = \frac{E}{R}$ and inserting values for E and R we get $C = \frac{110}{·2} = 550$, hence 550 amperes is the current taken by the lamps.

2. How many volts are required to force a current of 48 amperes through a circuit having a resistance of three ohms?

$$E = C\,R = 48 \times 3 = 144\,.$$

Hence 144 volts would be required.

3. Find the resistance of a circuit where 40 incandescent lamps, each taking ·5 of an ampere, are run at a pressure of 100 volts.

The total current will be $40 \times \cdot 5 = 20$ amperes, therefore

$$R = \frac{E}{C} = \frac{100}{20} = 5.$$

Hence the resistance is five ohms.

4. A certain copper wire has a resistance of three ohms. If this were replaced by an iron wire twice as long and half the diameter, what would be its resistance? First of all, the relative resistance of iron is, say, 6·4, and that of copper is 1·06, hence the iron wire has $(6{\cdot}4 \div 1{\cdot}06)$ times as much resistance as the copper wire,

or, $$\frac{6{\cdot}4}{1{\cdot}06} \times 3 = \frac{19{\cdot}2}{1{\cdot}06} \text{ ohms.}$$

Second, the iron wire has double the length of the copper wire, and has one-half the diameter, so the resistance must now be multiplied by 2 and again by 4,

or, $$\frac{19{\cdot}9}{1{\cdot}06} \times \frac{2}{1} \times \frac{4}{1} = 145 \text{ nearly.}$$

Hence its resistance is 145 ohms.

5. Calculate the resistance of a copper wire 150 yards long and ¼in. diameter. Applying our rule we have

$$R = \frac{L}{D^2 \times 93{,}000} = \frac{450}{{\cdot}0625 \times 93{,}000} = {\cdot}077$$

Hence the resistance is ·077 of an ohm.

6. A dynamo working with 100 volts pressure at its terminals delivers a current of 10 amperes to a group of lamps 200 yards distant; there must not be a greater drop of potential along the line than 2 per cent. What must be the diameter of the wire used?

As the total loss is 2 per cent., this is two volts drop, or one volt drop in sending the current from the dynamo to the lamps, and one volt drop in returning from the lamps to the dynamo. We have now to find what resistance will absorb one volt in forcing 10 amperes through it. This evidently is $\frac{\text{volts}}{\text{amperes}} = \text{ohms}$, or $\frac{1}{10} = {\cdot}1$ of an ohm, so that a resistance of one-tenth of an ohm will cause a drop of one volt in sending 10 amperes through this resistance. From this, it is seen that one length of wire between the dynamo and the lamps—namely, 200 yards—must not have a resistance more than ·1 of an ohm; similarly for the second or return wire. The length and resistance are given, and the diameter is wanted.

Now, $$R = \frac{L}{D^2 \times 93{,}000} \therefore D = \sqrt{\left(\frac{L}{R \times 93{,}000}\right)};$$

$$\therefore D = \sqrt{\left(\frac{600}{{\cdot}1 \times 93{,}000}\right)} = \sqrt{({\cdot}0645)} = {\cdot}254.$$

Hence the required diameter of the wire is a little over ¼in.

Conductors and Insulators.—All substances, so far as we know, will conduct electricity to a greater or less extent, and the property which a substance has for conducting, or acting as a medium for the passage of electricity, is named its "conductivity." A good conductor offers little resistance, and a bad conductor offers great resistance; a bad conductor is called an insulator, so that a good conductor acts as a bad insulator, and a good insulator acts as a bad conductor. The various metals conduct best, hence their conductivity is very high; silver takes the first place, and is put down as the standard. Copper follows close behind, and the other metals take their place in order. Acidulated liquids come next, then other liquids, such as sea and fresh water, etc. (oils excepted); wet wood is considered as a partial conductor, hence great care should be exercised in seeing that the wood enclosing or supporting conductors is sound and dry. Dry wood belongs to insulators; nearly all other materials are classed as insulators.

There is no defining line between conductors and insulators, as may be judged by the note just given respecting wood. It was stated that there is no substance that absolutely checks the passage of electricity, and, on the other hand, there is no substance that does not offer *some* resistance. Hence, we may divide substances into two classes—one class to conduct electricity, called "conductors," and the other class to stop electricity, called "insulators."

In the following table, the best conductor is placed first. Half-way through the list the conductors have such bad conductivity that the next commences the insulator class, and those following have been put as near as possible in their proper order; the nearer the end of the list, the worse the conductivity or the better the insulator. It is difficult to say exactly as to the relative position which several insulators at the bottom of the list should occupy. There seems to be little reliable information. Some insulators lose a good deal of their insulating quality as time goes on, so that although tests will give a very high initial result, it is found that they drop off considerably after use, and so become of lower insulating quality than others that were initially lower, but remained fairly constant.

TABULATION 15.

Classed as Conductors.	*Classed as Insulators.*
Silver.	Dry wood.
Copper.	Cotton.
Silicon bronze.	Marble.
Gold.	Paper.
Aluminium.	Oils.
Zinc.	Porcelain.
Phosphor Bronze.	Wool.
Platinum.	Silk.
Wrought iron.	Sulphur.
Tin.	Sealing wax.
Cast steel.	Resin.
Lead.	Vulcanised bitumen.
German silver.	Mica.
Platinoid.	Guttapercha.
Mercury.	Flint glass.
Carbon.	Shellac.
Acids.	Vulcanised indiarubber.
Sea-water.	Ebonite.
Fresh water.	Paraffin wax.
The body.	Dry air.
Wet wood.	

The various woods possess a great difference in resistance; the best insulator is put first in the following list:

Teak (best).	Lignum Vitæ.	Pine.
Walnut.	Rosewood.	Mahogany (worst).

The following tabulation gives the relative conductivity of some of the more important materials used as conductors and insulators:

TABULATION 16.

Material.	Conductivity.	Material.	Conductivity.
Silver (annealed)..	100	Mercury	1·6
Copper (hard drawn)	92	Carbon	0 05
Silicon bronze......	90	—	—
Phosphor bronze..	24	Mica	$\frac{1}{6 \times 10^{17}}$
Platinum...........	16·6	Guttapercha	$\frac{1}{30 \times 10^{17}}$
Wrought iron......	15·6	Flint glass	$\frac{1}{300 \times 10^{17}}$
Cast steel	9·6	Shellac	$\frac{1}{600 \times 10^{17}}$
Tin	11·4	Indiarubber (vulcanised)	$\frac{1}{1{,}000 \times 10^{17}}$
German silver	7·2	Ebonite	$\frac{1}{1{,}900 \times 10^{17}}$
Platinoid..	4·4	Paraffin wax	$\frac{1}{2{,}300 \times 10^{17}}$

The last seven materials are insulators of the best kind, and their enormous resistance as compared with the conducting metals can be observed.

It may be mentioned that 10^{17} signifies one hundred thousand million millions (100,000,000,000,000,000).

(To be continued.)

A NEW ELECTRICAL DISTRIBUTION SYSTEM.

Certain improvements in electrical distribution have recently been completed by Messrs. J. E. H. Gordon, which have been patented by their chief engineer, Mr. T. Tomlinson, by whom the improvements have been devised.

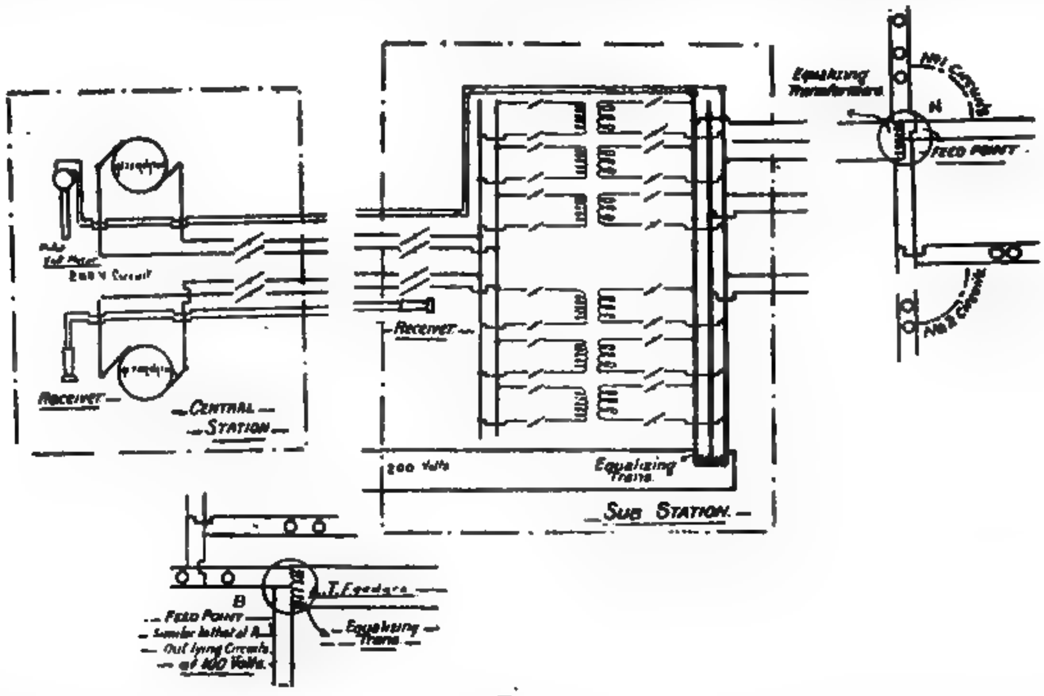


Fig. 1.

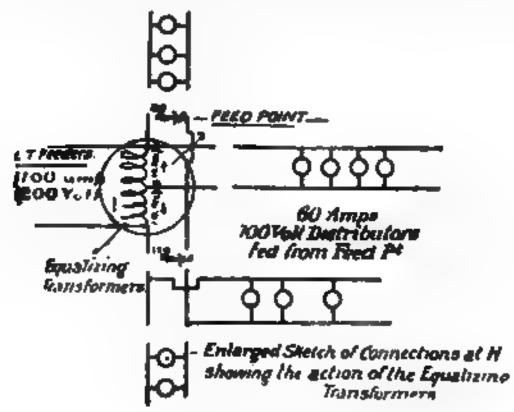

Fig. 1a.

The improvements relate to two parts of a distributing network. The first refers to low-tension mains, and is equally applicable to all kinds of distribution in which such mains are used. The second refers to distribution of alternating currents on the three-wire system—that is to say, to the *arrangements now* becoming common of causing the transformers at the sub-stations to give 200 volts and distributing the low-tension current on the three-wire system.

With regard to the first improvement, low-tension mains are at present laid either in the form of copper strips, which are placed in conduits and stretched, or in the form of insulated cables either laid in iron or earthenware pipes or buried in the ground. The introducers of this new system claim that great difficulties have been incurred by the copper-strip system, as the entrance of any water into the trench destroys the insulation, and the giving way of any of the tightening appliances causes the strips to slack and causes short circuits. They are further, when

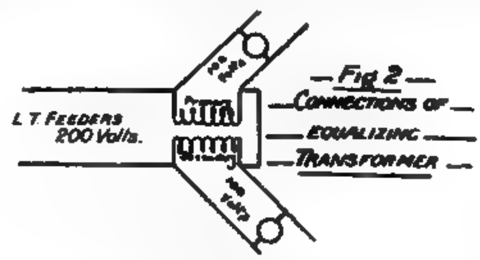

Fig. 2.

of a large size, not applicable to alternating-current distribution.

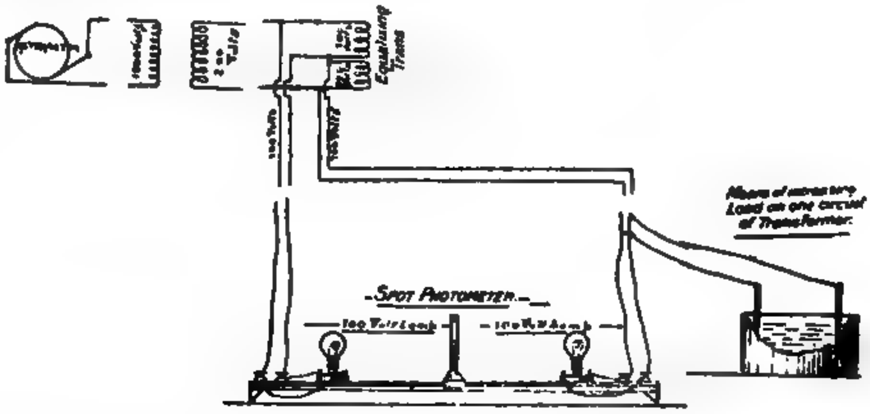

Fig. 3.

The system adopted by Messrs. Gordon is illustrated in Fig. 4, and in it the conductors consist of hollow copper tubes. These tubes are carried in porcelain insulators having the appearance of an ordinary nut or washer. They

are simply slipped on to the tubes and laid in concrete trenches. The trench is then filled up solid with an asphalte of a special composition, which is extremely cheap, and can be poured in nearly cold. The ends of the tubes open into the manhole boxes, and being hollow and presenting a large cooling surface, excessive heating is prevented.

Alternating currents, which, it is well known, travel only in the outside portions of large conductors, can be passed with full effect through the largest sized tubes used.

The stock sizes used by Messrs. Gordon are tubes having external diameter 2½in., 1½in., 1in., ¾in., and gauges from 9 to 19. Pilot wires or telephone wires can be drawn into the tubes if required, but are laid in the trench if laid at same time as the tubes, and in case the section of the conductor is at any future time not found sufficient a bare copper strand can be drawn in to reinforce it.

The important feature of the system, however, is the self-healing properties of the insulating arrangement. The first test of insulation resistance does not test quite so high as the highest class of cables, but it is practically impossible to injure it. In case of any fault occurring a little heat is developed at the fault, which at once melts the asphalte in the neighbourhood, but it then flows in and repairs the fault.

In the course of the experimental test recently undertaken by Messrs. Gordon, a piece of wet clay fell upon the asphalte before it was set, and gradually sank through it

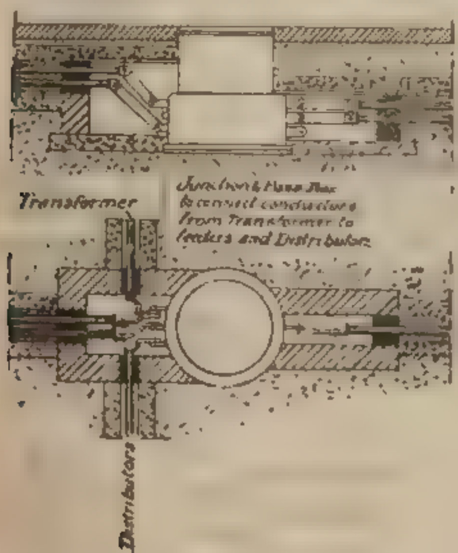

Fig. 4.

and formed a connection across the tubes. The insulation resistance at once fell very considerably, though not sufficiently to stop the use of the mains. Bubbles appeared for about three-quarters of an hour over the point where the clay had sunk in, and at the end of that period the insulation resistance rose to its full amount, and the main appeared to be in perfect order. On removing the clay afterwards, it was found to be baked hard and dry. It is intended to use this system at present solely for circuits not exceeding 200 volts, but Messrs. Gordon have an experimental length of it at Bray in practical work which has continuously 1,000 volts connected to it, and which remains in perfect order.

The cost of this system is said to be considerably less than the cost of the ordinary systems at present in use.

The second improvement—namely, the modification of the three-wire—is as follows: In the ordinary three-wire system a central wire has to be used throughout, which in itself is costly, and till recently, though we cannot quite say now, owing to the legal position of matters, a heavy royalty had to be paid to the owners of the patents. In case of a considerable difference of load between the two circuits, either the voltages become different or the loads have to be equalised by the use of a switching apparatus worked by hand.

In Messrs. Gordon's system the current at 200 volts is conveyed from the sub-stations by two wires only to the various feeding points. At each feeding point is placed an equalising transformer connected as shown in Fig. 3. The two sides of this transformer are equal, or, in other words, its ratio or transformation is 1 to 1. When the loads on the two circuits are equal, the transformer does not act, and there is no loss by transformation, but when the loads become different, current is at once automatically transformed from the circuit which is the least loaded to the circuit which is heaviest loaded, and the voltages of the two circuits are kept exactly equal. Fig. 1 shows the general arrangement of town mains laid in this manner.

Fig. 3 shows an experimental test of the system. A pair of circuits were connected and one lamp was placed upon each. These lamps were placed on the two sides of a grease-spot photometer, and adjusted for equality. A liquid resistance, consisting of two metal plates in dilute acid, was then connected to one circuit in parallel with the lamp, and the plates were gradually approached until they were brought

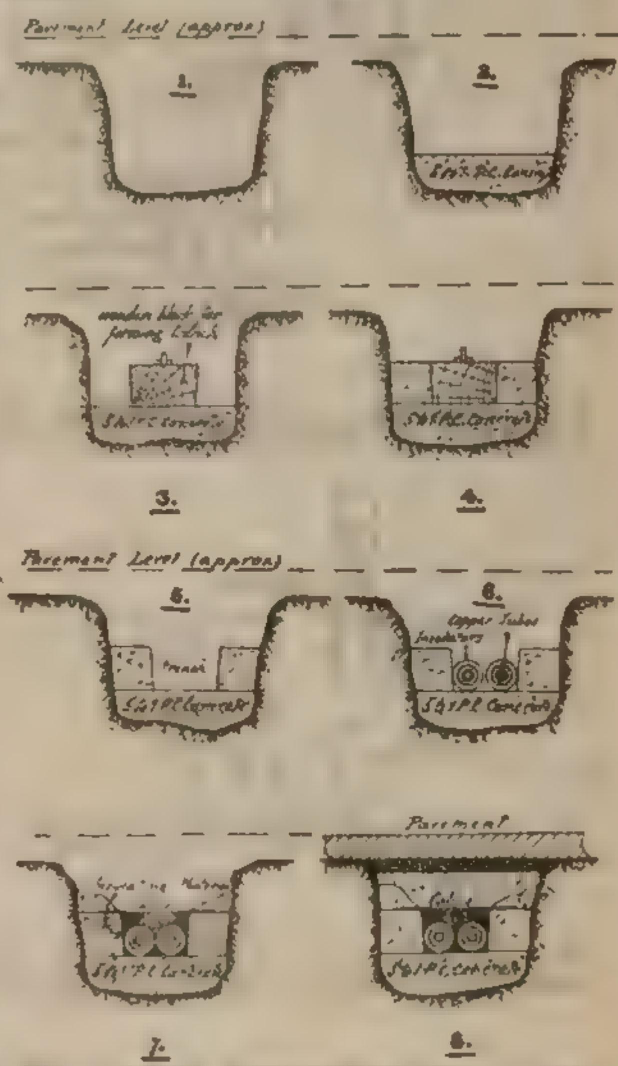

Fig. 5.—Section of Conduits, Showing Method of Laying.

into contact and the fuses melted. During the whole of this time, though the current on one circuit must have been at least 100 times the current on the other, no difference whatever could be detected on the photometer in the brightness of the two lamps. Fig. 5 (Nos. 1, 2, 3, 4, 5, 6, 7, and 8) shows sections of conduits and method of laying the mains.

HOVE.

The position of electric lighting in the Brighton district—where the Corporation and a private company are in competition—added a zest to the desire to know what was being done in the adjacent township of Hove. Upon receiving an invitation to be present at an "inauguration ceremony" at the Town Hall of Hove on Monday last, there seemed opened a way to get definite information as to the prospects at Hove. If a crowded room and an enthusiastic audience are evidences of future success, then the future of the Hove central station should be assured. It is not our intention

describe what is to be, because that in a great measure depends upon how generally the light is adopted. The outlook was referred to by various speakers and Lady Louisa Loder performed the ceremony of switching on the current. So far as we could gather, the meeting in the Town Hall, Hove, under the presidency of Mr. G. P. Woodruff, J.P., chairman of the Hove Commissioners, was intended to give information as to the present position and future prospects of the company.

The **President** said that after some years of serious thought and labour, they had met that day to inaugurate and formally open a very important section in their general system for the electric lighting of Hove. In this function they were assisted by a distinguished lady whom he would shortly invite to switch on the current. He gave a resumé of the action of the Commissioners in relation to the introduction of electricity in the town, and pointed out that the subject first engaged their attention in 1881, when what he characterised as a rather extraordinary scheme for the electric lighting of Hove came under their notice. It was at that period suggested that they should have what was known as tower lights on poles 200ft. high—"like miniature moons," humorously added the speaker, and the audience greatly appreciated this pleasant banter. Several proposals for the electric lighting of Hove were before the Commissioners in 1882, and application was made to the Board of Trade for their consent to a company being allowed to be established in the town for the purpose, but their consent was refused. In 1883, however, the Parliamentary Committee of the Commissioners recommended the Board to apply for powers to light the town, showing that even at that early time the Commissioners were alive to the importance of electric lighting. But proceedings, he explained, were difficult in consequence of a proposal on the part of the Board of Trade to issue a provisional order in some distinct form, and the matter was, therefore, "laid by" for the time being. Between the years 1886-9 renewed applications were made, and in 1890 their application was successful, and a provisional order was granted them. The Board, as a whole, had been of opinion that they should not undertake the electric lighting of the town at the expense of the ratepayers, and had, therefore, made a contract with experts, some of whom were on the platform, and he was happy to say that their experience so far had been highly satisfactory. "In the contract," continued the speaker, "we have guarded you as ratepayers in every way that is reasonable and proper. We have provisions as to the price, also as to discounts and as to the re-purchase of the undertaking after some years, and in other ways—in all ways, in fact—under the advice and assistance of the Board of Trade we have done all that is possible to protect you, and also to give this company to whom we have transferred our order all security, and I trust they will be able to make very good returns upon the capital. I am quite sure they will, because in three months they have laid down two and a half miles of mains in our streets in the most expeditious and in the most satisfactory way."

After a few remarks from **Mr. Woodman**, chairman of the Electric Lighting Committee,

Colonel Pilgate, as chairman of the Hove Electric Lighting Company, described the works. He explained that the company's plant would consist of two distinct portions—the generating station and the distribution system. Of these, the distribution system had been completed to the extent of about two miles out of the four miles required for the compulsory area, in a permanent manner, so that everything as now put down would remain in its present condition. The system of mains adopted was the one introduced by Messrs. Crompton and Co. in their various London contracts. It consisted of small culverts made of concrete, underneath the footways, in which the electric conductors made of bare copper were supported by porcelain insulators. There were movable covers to the culverts at distances of every fifteen yards, thus facilitating connections to houses and the drawing in of additional mains as might be required. The generating station was at present only in its temporary form. It would contain a generator more similar to those generally adopted in London. There would also be an accumulator-room containing sufficient storage in the shape of accumulators to perform the duty of acting as a reserve in case of sudden breakdown of the moving machinery, or of supplying the whole of the light required after 11 o'clock until four or five in the afternoon of the following day. This arrangement of supplementing the generating plant by storage batteries had the effect of making the light absolutely steady and free from those slight occasional jumps or flickers which were noticed whenever storage was not used. The contract for the whole of the works had been placed with Messrs. Crompton and Co., Limited, London and Chelmsford.

Lady Louisa Loder hereupon successfully switched on the current.

Mr. R. E. Crompton, in one of his characteristic speeches, assured the gathering that it was the desire of the electric lighting company to make the light popular by making it perfectly trustworthy and reliable. He spoke of the value of the current for domestic purposes and, characterising the price as the bugbear of the light, declared that in London the current did not cost more than gas. Hitherto the wealthy user had been a good friend to them, but in future the poorer user would be their best friend. He hoped there would be a universal demand for the light, the price of which, if it were more extensively used, would be materially decreased as time went on.

Mr. Dowsing gave a practical illustration of the many uses to which the electric current could be put for household purposes, and there was subsequently an exhibition of food cooked by electricity and tasted by many of those present, the work of the electric cookers while frying, grilling, boiling, and baking being watched with interest.

COMPANIES' MEETINGS.

SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

In the presence of a large number of shareholders, the tenth ordinary general meeting of this Company was held on Tuesday, at the Cannon-street Hotel, under the presidency of Mr. J. S. Forbes, the chairman of the Board. After the **Secretary** (Mr. H. C. Glover) had read the notice convening the meeting,

The **Chairman** moved the adoption of the report. In doing so he commenced with the profit and loss account. They would see, he remarked, that the sales, less commissions and allowances, amounted to £9,498, as against £15,348 in the corresponding year. At the first blush that was rather disturbing—that sales one year of £15,348 should diminish to £9,498 in the one following. It looked bad until it was explained. The fact was, they had a special order for 100,000 lamps for Australia at a very fair price, and the amount happened to come into the larger account. The lamps had been made from time to time and when they had occasion to sell them they did so. If they took the net price of those lamps—close upon £10,000—they would see that the sales of the lamps upon the local business was about £5,348. Bearing that in mind, the local business had this year increased from, say, over £5,000 to £9,498; in fact, it had nearly been doubled. In transfer fees there had been a slight diminution; people had apparently not been so anxious to transfer their interests in the Swan Company. The dividend on the shares in the French Company was £1,405 as against £1,178, that company having paid 5 per cent., as compared with 4 per cent. in the previous year. Competition was bringing prices down, but notwithstanding that he thought he might say that that company would this year show as good a dividend, and probably a larger one. The dividend on the shares in the Edison and Swan Company amounted to £37,094, as against £34,799, which was an increase. Of course, as they (the Swan United) had a very large share of their capital invested in the Edison and Swan Company, they participated in the improvement in their position. The stock, upon which depended the final adjustment of accounts, had been written down so as to render their position sounder in every respect, and that was the main cause of the diminution in the dividend. They proposed, as would be observed, to pay 1 per cent. less than in the corresponding year. The stock brought forward from last account was £18,449, and it had been reduced to £14,654. If they had left the stock at that value in the books they would have had about £3,800 more to divide. When he came to the question, he would tell them why they had thought it wise to reduce the value of the stock; that question would naturally arise when they came to the value. Coming to the debit side—purchases meant raw materials, although in some cases it referred to manufactured material, but chiefly raw materials which they worked up into lamps. The general charges, including all these variety of things—salaries, rents, directors' fees, law charges, etc., as set forth, amounted to £3,639. Then came wages and expenses at factory to £3,637, and sales ledger reserve to £200. The last item, he explained, was reserved to cover the risk of bad debts, because when the accounts were made up at the end of the year they found that that reserve fund was trenched upon to that amount. The purchases included the item of platinum, which had been a very errant quantity. They, both the Edison and Swan and the Swan Companies, were forewarned by competent judges that they would be wise to lay in a considerable stock of platinum, the output of which, chiefly in Russia, was very limited, and was mainly in the hands of a ring. Although largely used in electric lighting, he was somewhat surprised to find that the chief competitors of the electric lamp were American lamps. He could, however, not understand in the particular lamps in which they dealt, that continuity of life and indestructibility were so invaluable as in their lamps. However, the Company bought in advance a considerable quantity of platinum. In the Edison and Swan Company they were fortunate enough to utilise most of the material before a fall in the price of platinum set in, but that was not the case with the Swan Company. They had bought the material at an average price of 60s., and they could now buy it at about 30s. The price of platinum had fallen and advanced during several years, but they had considered it a prudent one, to write it down in the balance-sheet. Possibly by next year the rate at which they had written it down would be less than the market rate; then they could write it up. From the necessities of the business, they were obliged to retain large numbers of lamps in stock. In Germany they were compelled to keep a large variety of lamps which in each case amounted to no great sum, but in the aggregate reached a very considerable number. When they got up to 320,000 lamps, it implied a considerable amount of money locked up. They were face to face in Germany with severe competition in the lamp business, as they were also in France, and he supposed they would be in England sooner or later. They had therefore written the lamps down from 9d. to 8d., and 1d. on 320,000 lamps was an appreciable quantity. Well, these two matters and others of less importance accounted for what might have been brought forward, and which had led to the writing down of the stock to £14,654. They had thought it more prudent to do that than to declare 11 per cent. as they did last year. By following out this policy they had placed their balance-sheet on a sounder footing, and had brought it into line with the circumstances of the moment. In the production of a lamp platinum at 60s. meant 2½d., and at 30s. only 1¼d. The greater the quantity of lamps manufactured the less was the relative cost of production. In Germany, what was going on there at that moment was very

German indeed. There were in that country three companies who had resources and knowledge enough to carry on the lamp business. He supposed that he was not treading on false ground when he said that as far as they could ascertain, the lamp which they made in Germany was certainly as good, if not better, than those manufactured by their competitors. The first was the firm of Siemens and Halske, who made lamps by some arrangement with the Edison Company and on Edison's patents. Another great company was that which bought of Mr Edison for Europe the patents which they (the Swan United) purchased for Great Britain. The German Edison Company both made lamps and put up installations. Certainly a number of people had learned how to make lamps, and when they had got together a little money they started a lamp factory; but their only chance was to commence at impossible prices. Now these three companies had appreciated that position which they had not initiated, but had followed. They had determined to kill those small lampmakers, which was an idea unfamiliar to them in England. It would, however, result in the survival of the fittest, and the price of the lamp, which was now very low, might then be regulated so as to produce rather better results. That was their hope. That was what they had gone through during the last half year, and that was why their accounts and sales showed less favourable results than they might have if the prices had been equal to those of the corresponding year. Another feature, which was more or less problematical, was that in the depreciation in the price of the lamp, there was a possibility that the relative consumption would increase. If they paid 2s 6d for an article, they were likely to be more careful about the use of it than if they bought it for 1s 3d, and so with lamps. In the long run it did not matter whether they sold three lamps at 9d. or one at 2s 6d, because the profit was determined by the quantity they made. If they doubled their present quantity, they would probably produce the lamp at twopence less than the present price, and if they trebled their present output the cost of production would still be less. The matter turned exactly upon the number of lamps which could be divided into the fixed expenditure. He (Mr. Forbes) had received some letters from shareholders who expressed surprise at the reduction in the dividend. Although they paid less their position was really sounder. They had got to face the difference and as prudent men they had anticipated those sort of things. If they would again refer to the profit and loss account, they would see that the balance was £34,840 as against 39,000 in the corresponding period, that was about £4,000 less. This was mainly accounted for by the different evaluation of the stock. The next question was, what were they to do with the £34,840. They proposed to distribute it, retaining a reasonable reserve. They would see from the balance sheet that the Company had brought down a balance from the previous account of £8,010. The reason for having carried forward so large an amount was because the Directors foresaw then the question of prices, and that rectification of the balance sheet was imminent, and they had therefore considered it prudent to bring that forward from the previous year. They had already distributed for the first half year an interim dividend amounting to £14,558, and they now proposed to distribute a further sum at the rate of 12 per cent. for the half year. This would make the yearly dividend at the rate of 10 per cent., and enable them to carry forward about £6,000. The share capital stood exactly as it had during several years, namely, £375,071. There was one item in the balance sheet which had disappeared, namely, £3,885 in forfeited shares, which had been brought forward from time to time on one side of the account as a debt. It was no use bringing forward shares which had been forfeited. The money represented on the shares belonged to the Company, and instead of carrying forward an item which was likely to mislead, it had been thought better to knock it out of the accounts altogether. They had now written down the patent rights to £328,503. With regard to factory plant, they had got a portion of a large factory in Germany with certain standing machinery, but in order to make that factory efficient to turn out their commodity they had had to spend from £10,000 to £12,000. That money had, however, been written down to £1,570. Mr Forbes then mentioned the New and Prussian Consols, stock, cash on deposit and in hand, and observed that that was the whole story, which he could not enlarge upon, but having gone so far, he would proceed to paragraphs in the report. The first paragraph concurred with all that he had said in detail. "The profit and loss account for the year shows a credit balance of £34,840 11s 11d., which, together with £8,010 3s brought forward from the last account, makes disposable the sum of £42,850. 15s. 0d. An interim dividend in respect to the first half of the year, amounting to £14,558 9s 8d., has already been paid. The Board proposes that a further sum of £21,467 8s 4d be divided, free of income tax, and that £6,824 17s 9d be carried forward." They had, he said, rather a peculiar distribution. It was very puzzling and involved enormous calculation, and really after all there was nothing in it. They had two classes of shareholders, partly paid and otherwise. "The distribution of this amount in accordance with clause 77 of the articles of association will work out at 4s 2½d per share on the 78,949 ordinary shares of the Company, £3. 10s paid, and at 4s 11¼d per share on the 19,750 £5 fully paid, being equivalent to 10 per cent. per annum on the partly paid and of slightly under that rate upon the fully paid shares. The dividend will be paid upon the register as it stood upon November 15, and the warrants will be issued on December 13." The litigation over the patents in Germany had fortunately come to an end. As long as they were in litigation in Germany, they laboured under the disadvantage of not knowing where they were. They could not push their trade because the German law was rather peculiar on the subject of damages. Until one got a decision of the court, one did not know where one was. There was first the validity, and, secondly, the damages. How much would one be mulcted in? As prudent men, with the case before them, they did not push the trade, but made the best of the matter. Of course, they no doubt made some sort of provision that the question of damages might turn out awkward some day. However, they were not infringers, and they were left to proceed. That enabled them to push the business without the shadow of fear hanging over them. The Swan United had got some £30,000 invested in the French Edison Company, which had been made an Edison and Swan Company. That company paid 5 per cent. last year, and showed a possibility of future value. Their partners there were the people who had the putting up of installations in large parts of Paris, etc., and they were getting a good price. Their agreement precluded the Swan, and indeed the Edison and Swan, from travelling on the Continent, with the exception of in Germany. Mr Forbes did not admire the principle of compulsory service in that country, although he was bound to admit that the workmen were thereby more disciplined, and that enabled them to deal with workmen on more reasonable terms than those not so trained. It all amounted to this: they would be able to turn out the lamps in Germany scientifically as perfect, mechanically as perfect, and at less cost, he fancied, than either in France or in Great Britain. That was a very important lever for them. For some time they had supplied their French friends with lamps made in London, they could now furnish them with lamps manufactured in Germany at a great deal less than in Paris. Paris had, however, a kind of London Trades Council which regulated the prices of wages, but in Germany they were not encumbered with such an institution. If they could induce their French neighbours to take lamps from Germany, that company would pay more than 5 per cent., but they would not do so. The Swan United was allied here because a large portion of their capital was invested in the Edison and Swan Company. They had a portion of it safe in the French Company, and they had the German residuum. This it was proposed to amalgamate with the British Edison and Swan Company. As mentioned in the report "the Board believed that the time has arrived when a fusion of the residuum of the foreign business of the Swan Company with the British Edison and Swan Company may be effected with advantage to both interests, and negotiations are pending with a view to effecting some arrangement in this direction." Mr Forbes observed that he was the happy man who held the balance between two interests. The fusion ought to be effected both as an economic and as a defensive measure, as that would make both companies richer and stronger. Mr Quilter and Mr Swan on this side and the Earl of Lichfield and Sir John Lubbock on the other should be able to think the matter out properly. Some arrangement might be made under which the Swan Company should be merged into the Edison and Swan Company. The negotiations on this matter were pending, and the only question now lay in the figure. The theory was that the Edison and Swan Company should purchase that residuum of the Swan Company at a price, with a commodity to be called debenture stock bearing some reasonable rate of interest. He only mentioned the matter on that occasion so that the proprietors might know that there was something pending which was greatly in the interests of the Company. A special meeting would, of course, have to be called of both companies, and it would be for them either to accept or reject the proposition. Mr Forbes then referred to the great loss to the Company in the death of the late Mr Leyland, deputy-chairman, who had been succeeded by Major Flood Page. If the two English companies were amalgamated, there would be no necessity for the present Board, and there would be a saving of £2,500 a year. He then moved the adoption of the report and accounts.

Mr W Cuthbert Quilter seconded the motion.

Mr Skipworth did not regard the balance sheet as satisfactory. It seemed to him that they were carrying on their factory at a loss. He was glad to hear that some progress had been made towards the fusion of the two companies, but Mr Forbes had said the same thing last year. It appeared to him that the negotiations should not occupy a period of a year or 18 months. He would be glad to hear whether they were approaching a conclusion in the matter.

Mr Forbes, who had already answered these questions in his remarks, repeated them.

The motion was then put to the meeting and was unanimously adopted.

The **Chairman** then proposed: "That in addition to the £14,558 9s 8d already distributed in respect of the six months ended March 31, 1892, a further sum of £21,467 8s 4d be divided, free of income tax; to be distributed in accordance with the provisions of clause 77 of the articles of association, making a total distribution for the year of £36,025 18s." The distribution of the amount £21,467 8s. 4d., in accordance with clause 77 of the articles of association, will work out as follows: on the 78,949 shares, £3 10s paid, 4s 2½d per share; on the 19,750 shares, £5 fully paid, 4s 11¼d per share; being, with the interim dividend previously paid, equivalent to 10 per cent. per annum on the shares £3 10s paid, and of 8⅞ per cent. per annum upon the shares £5 fully paid.

This resolution was also seconded by **Mr Quilter**, and was carried.

Mr Forbes and Mr Batt, the retiring directors, were then re-elected, as were also Messrs. Welton, Jones, and Co., the auditors. This brought the general business of the meeting to an end, after which **Mr Forbes** made some lively comments on a letter which he had received from a shareholder.

A vote of thanks to the Chairman and Directors concluded the proceedings.

INTERNATIONAL OKONITE COMPANY.

Mr Alexander Armstrong presided on Wednesday at the Cannon-street Hotel, at the annual general meeting of this Company. A letter, however, was read at the outset of the proceedings from Mr. Samuel Pope, Q.C. (the chairman of the Company), stating, among other things, that the Manchester factory absolutely required an immediate reorganisation of its administration, and suggesting the adjournment of the meeting.

The Chairman accordingly moved its adjournment until January 10, stating that they would then have an ample opportunity of considering the balance sheet, and Mr Pope would then be in a position to give them a better explanation of their affairs than he himself could.

The motion was seconded by **Mr. J. H. Todd**, but was strongly opposed by several of the shareholders.

Ultimately, however, it was agreed to.

NEW COMPANIES REGISTERED.

L. Alwyn, Limited.—Registered by E. G. Van Tromp, 16, Essex street, Strand, W.C., with a capital of £2,000 in £1 shares. Object: to carry on the business of electricians and electrical engineers in all its branches, and as agents for the Brush Electrical Engineering Company, Limited. Registered without articles of association.

R. C. Cutting, Douglass, and Co., Limited.—Registered by J. D. B. Lewis, 20, Bucklersbury, E.C., with a capital of £10,000 in £5 shares. Object: to acquire as a going concern the business of lightning conductor manufacturers and electrical engineers now carried on by R. C. Cutting, Douglass, and Co., Limited, and to carry on and extend the same in all its branches. With slight modifications, the regulations contained in Table A apply.

Electrical and General Contract Corporation, Limited.—Registered by Clarence Leighton, 12 and 13, Clement's inn, Strand, with a capital of £50,000 in £6 shares. Object: to enter into, or acquire by purchase or otherwise, and carry out, contracts and concessions or other grants in any part of the world, for making, purchasing, or working railways, tramways, telegraphs and telephone lines, electric and other lighting, electric, hydraulic, and other works, and for the equipment of any such undertakings with electric or other plant, stock, or apparatus, etc. The first signatories are:

	Shares.
J. F. Mieville, 12, Angel court, E.C.	1
W. S. G. Baker, 35, Parliament street, S.W.	1
A. de Turckheim, 135, Parliament street, S.W.	1
H. Chestermaster, Jeffrey square, E.C.	1
D. Parrish, 2, Copthall buildings, E.C.	1
G. E. Church, Dashwood House, E.C.	1
F. Manelli, 101, Leadenhall street, E.C.	1

There shall not be less than two nor more than seven directors. The first are W. S. Graff Baker and Alfred de Turckheim. Qualification, £100. Remuneration, £100 each per annum.

Sir James Farmer and Sons, Limited.—Registered by Last and Sons, 19, Pall-mall, S.W., with a capital of £50,000 in £10 shares. Object: To acquire and undertake the whole or any part of the business of the firm of Sir James Farmer and Sons, engineers, Salford, Manchester; generally, to carry on the businesses of machinists, mechanical and electrical engineers, machine and tool makers, boiler-makers, etc., in all their respective branches. The first signatories are:

	Shares.
A. W. Farmer, Adelphi Iron Works, Salford, Lancashire	1
J. S. Farmer, Adelphi Iron Works, Salford, Lancashire	1
M. Watts, Victoria park, Manchester	1
J. H. Storey, Lancaster	1
S. Watts, Victoria park, Manchester	1
C. A. Farmer, Adelphi Iron Works, Salford	1
G. P. Watts, Brook House, Levenshulme	1

There shall not be less than four nor more than seven directors. Qualification: One share. Most of the regulations contained in Table A apply.

BUSINESS NOTES.

Stockholm.—An electric tramway is to be established at Stockholm.

Budapest.—A company has been formed to run the Budapest electric tramways.

Brussels.—Tenders will shortly be required for lighting the Brussels Hotel de Ville.

Coal-Getting.—The North Hungarian Coal Company are installing electric coal cutters by Messrs. Ganz and Co.

Antwerp Electric Railway.—The scheme for an electric railway between Antwerp and Brussels has been set aside.

Siemens and Halske, of America.—The *Electrical World's* Chicago correspondent sends an interesting account of the progress of this firm, who are building motors of 1,000 h.p.

Scarborough.—The idea of the immediate introduction of electric light is being received with much enthusiasm in Scarborough.

Thomson European Welding.—A meeting of shareholders of the Electric Welding Company has been called by a banking house in New York.

Andaman Cable.—The question of connecting Port Blair with the Andaman Islands has been shelved by the Indian Government on account of the expense.

Harwich.—The Corporation of Harwich in another column advertise their desire to have tenders for the purchase or hire of their electric lighting powers.

Bath Asylum.—The new Bath and County Asylum at Bishop's Lydeard, near Taunton, is estimated to cost £140,546, of which £2,500 is for electric lighting.

Underground Wires.—At Bournemouth, Councillor Hankinson will move at the next meeting of the Town Council that all telephone wires should be placed underground.

Penmaenmawr.—At the last meeting of the Local Board the clerk was instructed to write to Dolgelly for information as to the comparative cost of gas and the electric light.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino-Brazilian Company, were £3,079.

Milan.—A scheme is approved for the establishment of an overhead conductor system of electric tramways at Milan by the Societa Edison. The water power at Paderno will be utilised.

Push-Button Switch.—Mr George Cutter has brought out in America, a push button switch, a light touch being sufficient to turn on or off the light. The same kind of action is also attained with a pull cord.

Simla.—It is feared that the project for the electric lighting of Simla will have to be abandoned on account of the expense. Perhaps if a less expensive firm had the contract in hand the proposal might yet be saved.

Teignmouth.—A requisition has been presented to the Teignmouth Local Board by the ratepayers to call a public meeting to discuss the extension of the gas works or the installation of a central electric station in the town.

Chairman.—Mr J. B. Braithwaite, jun., having been elected chairman of the Brush Electrical Engineering Company, Limited, in succession to the late Duke of Marlborough, has accepted the appointment for the period of one year.

Ledbury.—Mr J. C. Davies, of Fair Tree Farm and Brick Works, has the honour of being the first to introduce the electric light into the neighbourhood. The works and dwelling house are both lighted from an engine used at the works.

Belfast.—Tenders are invited for the electric lighting of Queen's Quay, Abercorn Basin, and the Hamilton Graving Dock, by the Belfast Harbour Commissioners. Tenders by 5th December to Mr. W. A. Currie, secretary, Harbour Office, Belfast.

Newark.—A proposal is made to light the Newark Town Hall with gas, but this it is thought by others, should be left over till the receipt of the Electric Lighting Committee's report, which may recommend an immediate introduction of electric light.

Brazilian Submarine Telegraph Company, Limited.—The Directors of this Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, tax free, for the quarter ended September 30, payable on December 21.

Larne.—The Larne Commissioners are not altogether satisfied with the light they have been receiving and have written to the contractors to state that they will deduct for light when not received. A recent failure was, we learn, due to bad cables.

Santiago.—Tenders are invited until March 1, 1893, for the electric lighting of Santiago, Chili. A specification, and a plan of Santiago, can be inspected, on personal application, at the Commercial Department of the Foreign Office, on any week day between 11 and 6.

City and South London Railway Company.—The receipts for the week ending November 27 were £503, against £[illegible] for the corresponding period of last year, or an increase of £[illegible]. The total receipts for 1892 show an increase of £1,727 over those for the corresponding period of 1891.

Warminster.—At the monthly meeting of the Local Board the chairman stated that his gift of a drinking fountain would reach Warminster in a fortnight's time, and it was decided to try both the arc and incandescent electric lamps before deciding which of the two should be erected over the fountain.

Buxton.—At the meeting of the Buxton Local Board the chairman stated with reference to the electric lighting question, that no notices had been given, and neither the Board nor anyone else could obtain powers; consequently it had been considered best to drop the question for 12 months to consider it.

Liverpool University Clock.—A large clock, with dials 11ft. in diameter, has been presented to the city of Liverpool. The clock also drives three large dials inside the building by an electrical arrangement attached to the clock works. The whole were supplied and fixed by Messrs. Wm. Potts and Sons, Leeds.

Extension of the Electric Railway.—The City and South London Electric Railway Company have given formal notice to the Lambeth Vestry of their intention to begin the construction of

their extended line from the present terminus at Stockwell to Clapham Common, under the powers obtained by them under the Act of 1890.

Edison Swan Offices.—Great interest is manifested by passers in the City at the magnificent show made by the Edison Swan Company at their new City offices at 110 Cannon-street. The large windows are filled with all varieties of incandescent lamps, many of them ablaze with light and colour, the whole making a most attractive show.

Cheap Lamps.—Circulars from continental lampmakers show that lamps are now sold to fit any socket in lots of thousands at 1f each, free on board any European port. They are being sent to America, and with duty 45 per cent. and freight charges, they still only come to 1s 3d. each, 100 per cent cheaper than the cheapest American lamp.

Belfast.—At the meeting of the Belfast Gas Committee last week, it was reported that Prof. Alexander B. W. Kennedy, F.R.S., 19, Little Queen street, Westminster, London, had been appointed consulting electrical engineer to the Belfast Corporation. The site of the first electrical works will, it is understood, be on the banks of the Lagan, off Laganbank-road.

Bromley.—A movement in the direction of electric lighting is being made in Bromley, the Board having asked those willing to take up the new light to fill up forms intimating the extent of their requirements. According to the official estimate, the Board put the cost of the electric light at 32s 6d. per annum plus the hire and maintenance of the meter and other appliances.

Swindon.—In our advertisement columns will be found a notice by the Swindon New Town Local Board inviting tenders for lighting the public streets by electricity or otherwise, for one year commencing on January 1, 1893. Tenders are to be sent in by the 12th day of December. This will allow about a fortnight to start. A good feeling towards electric light exists in influential quarters in the town.

Personal.—We understand that Mr. Alfred Slatter, A.I.E.E., has retired from the Planet Electrical Engineering Company, and, besides several consulting appointments, has joined the firm of Messrs. Julius Sax and Co., of Central Markets, Smithfield, E.C., and Ridgmount street, W.C., as their manager. Mr. E. J. Tumber has resigned the position of general manager to the Electric Stores, Limited.

Kingston.—At a special meeting of the Kingston on Thames Town Council last week, it was resolved to introduce electric lighting into the borough, and to communicate this decision to the Surrey County Council, in order that arrangements may be made for the electric lighting of the new county buildings when completed. Mr. W. H. Preece has been asked by the Town Council to report.

Auction Sale.—An important sale by auction is announced by Messrs. Wheatley Kirk, Price, and Goulty, of engineering and electrical plant and machinery, dynamos, motors, gas engines, and other material, at the East Down Electrical Works, Lewisham. The materials, which were used in a regular electrical manufacturing and contracting business, comprise some eminently practical pieces of machinery. The day of sale is December 13.

Blackpool Tower.—The construction of the great Blackpool Tower is now progressing fast. The four legs have all been put down, and the main and gallery girders fixed, and by next week the next section, which advances another 85ft., will be commenced. Large arc lights have been erected upon the site of the tower, and at night a current from the dynamos at the Aquarium provides a brilliant light, by the aid of which the work is carried on in overtime.

Commercial Cable Offices.—The Commercial Cable Company have opened a branch office in East India-avenue, Leadenhall street, from which messages are sent direct to the cable ends. The Commercial Cable Company connects with the Postal Telegraph Company of America, reaching all important places in the United States; with the Canadian Pacific Telegraphs throughout Canada; with Bermuda, the West Indies, and Central and South America.

Electric Fire Bells for Bournemouth.—The report of the captain of the Bournemouth Fire Brigade, in which he recommended the Council to adopt the system of electric fire bells in addition to the present telephones, and also that the Council should keep horses suitable for drawing fire engines, was read at the meeting of the Lighting Committee. The report was referred to the surveyor for him to confer with the captain of the fire brigade, and report more in detail.

Edinburgh.—At the meeting on Monday of Edinburgh Town Council, the Lord Provost impressed upon the members the fact that one half of the three years' period for which the electric lighting provisional order endured had already elapsed, and suggested that something should now be done as to enquiring into the best systems of lighting in vogue. After some conversation, it was agreed that at next meeting a deputation should be appointed to visit different towns and acquire information.

Chatham.—At the meeting of the Chatham Town Council last week, it was moved and carried that notice be forthwith given to the Chatham, etc., Electric Lighting Company as follows: "That all roadways and footpaths broken up for the company's purposes, and which they have failed sufficiently to restore within three weeks after being broken up, will be taken in hand by the Corporation and completed at the expense of the company, unless the said roads and footpaths be duly reinstated within seven days after notice."

Incandescent Gas Lights.—It was recently stated in a lecture given by Prof. P. B. Lewes, the well known gas expert, that to obtain a light of 48 c.p. for 2,000 hours by the incandescent gas light system, would cost 30s. (with gas at 3s. per 1,000ft.), including renewals, while by the incandescent electric light the cost would be 245s., or more than eight times the amount. The problem as stated may be worth the attention of the calculating powers of those on the other side of the question.

Fire Risks.—That there has been rather unnecessary ardour on the part of the fire insurance officials to swell the list of accidents by electric light is the opinion of the *Financial News*. Many of the instances do not seem to be authenticated to the point that is properly required in such a schedule. Comparative immunity from accidents by fire is one of the strong points of the electric light, and if it is to be robbed of this prestige, maintains our financial contemporary, it should be on the best evidence.

Proposed Victoria-Kilburn Electric Railway.—During the ensuing session of Parliament a Bill is to be promoted with the object of incorporating a company for the purpose of constructing an underground electric railway from a point on the Vauxhall Bridge road side of the Victoria railway station, and passing from thence under Edgware road to Kilburn. The gauge which it is proposed to adopt on this line will be the ordinary standard gauge adopted on all passenger railways of 4ft. 8½in., thus differing from several of the electric railway schemes already authorised or projected.

Ceylon.—The Eastern Produce and Estates Company, as agents for Messrs. Gilkes and Co., are open to erect electrical installations to transmit power derivable from water three miles or less from its source. This, says the *Ceylon Express*, opens up wide possibilities for many groups of estates in possession of the necessary water power, as several estates in the higher districts are. But, unless a number could combine together to secure power transmitted from water, the cost would be very high, judging by the table of rates submitted by the manager of the company above referred to.

Aberdeen.—The Gas Committee of the Town Council met on Wednesday—Mr. Farquhar, convener—and considered the question of electric lighting. A correspondence with Prof. Kennedy, Glasgow, was read, to the effect that his charge for superintending the work would be at the rate of 3½ per cent. on the plant laid down and £100 to cover his expenses. Prof. Kennedy is to prepare plans for the interior of the building where the plant is to be laid down, and on that work he will charge 2 per cent. The terms were accepted, and instructions given to get specifications prepared forthwith.

Electric Tramway for Lytham.—Notices have been posted along the route of the proposed tramway between Lytham and Blackpool, to the effect that the company intend applying to Parliament during next session for power to construct the line. The line will traverse the streets of Lytham to St. Annes, and thence to Blackpool. It will pass the new watering place, Fairhaven. Last year application was made to the Board of Trade for a provisional order, but it was withdrawn, as the Corporation of Blackpool opposed the scheme very strongly. It is now thought that no opposition will be given.

Hull.—It is expected that the electric lighting station at Hull will be completed about Christmas. The committee appointed to carry out the details in connection with the opening ceremony have determined to give the local installation contractors, most of whom are agents for the large electrical firms, the opportunity of exhibiting electrical appliances. The exhibition will be held in the Sessions Court, and it will probably be open to the public for five days. The object is to give the public the opportunity of gaining information and witnessing the advantages of electricity. Messrs. Crompton have arranged to give an exhibition of cooking by electricity.

Comparative Cost of Gas and Electricity.—Mr. C. J. Russell Humphreys in the American *Engineering Magazine* has an article on "The Relative Cost of Gas and Electricity." From the American standpoint, he concludes that to obtain the unit of light we require 40 per cent. more capital for electric light than for gas, and that the cost of producing this unit of light will be for electricity 20 per cent. more than by gas. An improvement will be made by using large dynamos, direct coupled, with triple-expansion engines, remembering also that gas can also be improved. Coal is wasted fearfully in both processes, and great rewards await those who reduce this waste and enable us better to utilise that precious possession—coal.

Brighton Electric Railway Proposal.—A Bill for powers to construct an electric railway from Brighton to Rottingdean, we understand, is to be introduced into Parliament next session. This railway, which will be nearly four miles in length, will commence near Paston place, Brighton, and proceed along the beach and foreshore "between high and low water mark at a distance of about 100 yards from the cliff" to Rottingdean. From the termination of the railway a jetty is proposed to be constructed for a distance of 200ft. into the sea. The railway will be constructed on the extraordinary "gauge" of 24ft., and provision will be made for the construction of the platforms at such an elevation as to be safe from interruption by the sea.

Dundee Town House.—At a meeting of the Dundee Property Committee of the Town Council last week, ex-Bailie Keith suggested that the Town Council should be among the first to patronise

the electric light, and he proposed that the city architect should take in contracts for supplying the Town Hall, the [illegible] Hall, and the whole of the offices with the new illuminant. The hope was expressed by some members that it would not be necessary to remove the fine crystal gasaliers from the Town Hall, and Mr Keith said that would be for the consideration of the architect, but in his own opinion, he thought it would be possible to run a wire along the stems of the gasaliers and substitute electric jets for the gas burners. The architect was instructed to forthwith arrange for obtaining offers for the work.

Twickenham.—The Lighting Committee of the Twickenham Local Board are occupying their attention with the desirability of introducing the electric light. The district is rather scattered, and an alternating current system would probably be preferable. A representative of Messrs. Hammond and Co. attended the last meeting of the committee, and explained a proposal for lighting the parish. His offer to submit an estimate without charge was accepted by the committee. We should advise this committee without further delay if they intend to introduce the light, not to potter with free estimates, which must necessarily be partial, but to engage the services of an independent consulting engineer, have the project fully discussed, and proper specifications and plans obtained, which should be publicly tendered for in the usual way.

Weston-super-Mare.—A special meeting of the Weston Local Board was held last week to consider the electric lighting question. The special point was whether the Board should carry out their provisional order, or should delegate the matter to a private company. To carry out the complete scheme, it was stated would involve an expenditure of £30,000, but not more than half would be required for present expenditure. The Board expended for public lighting last year £1,643, which would offer a fair return on the proposed expenditure. It would be a guarantee of more than 5 per cent. on £30,000 and if borrowed publicly would be sufficient to establish a sinking fund to extinguish the debt in 30 years. The example of Scarborough is quoted on the side of founding a company, but it does not appear that any definite resolve has yet been made.

Liverpool Town Hall.—The Finance Committee, at their meeting last week, decided to have the electric light installed in the large ballroom and the Council-chamber at the Town Hall. The cost will be about £360, of which £155 will be expended in the illumination of the large ballroom, £45 will be paid for cable, providing for the extension of the electric light throughout the building should the present experiment be a success, and £160 will be the outlay on the Council chamber, this sum including the cost of the fittings, which will be of an ornamental character. The gasaliers in the ballroom are to be taken down, cleaned, and repaired, on the completion of which work the electric light will be introduced into each. Arrangements are to be made to connect the mains of the Liverpool Electric Supply Company as soon as possible, so that the light may be used for the present season.

Western Telephones.—Mr. F. Dagger has resigned his position as superintendent of the Plymouth district of the National Telephone Company, and his connection with the company will cease on the 28th inst. Mr. Dagger entered the telephone service 11 years ago, having served four years with the Lancashire and Cheshire Telephone Company, in North East Lancashire, four years with the Western Counties and South Wales Telephone Company, at their head offices in Bristol, and three years as superintendent of the Plymouth district. While at Plymouth, Mr. Dagger has had exceptional difficulties to contend with, more particularly with the severe storms, including the well remembered blizzard, and on these occasions his skill and energy have been of utmost service. He leaves the company having aided during the last three years in the establishment of a greatly improved telephone service.

Huddersfield.—At the recent annual meeting of the Huddersfield County Council, with reference to electric lighting in the official statement for the year, the Mayor stated that the Local Government Board gave their sanction to the borrowing of £50,000 in May last, and the Council were then able to enter into the following contracts and commence work: For the buildings, machinery foundations, chimney, and flue, £8,348; for the generating plant, which will be capable of supplying the energy for 4,000 16-c.p. incandescent lamps, including underground mains, transformers, and controlling apparatus, £20,640; for the 10in. cast-iron pipes for carrying the water required for condensing from the canal to the electric supply station and back to the canal, £406—making a total of £29,394. It was hoped that the electric supply would be commenced in the spring of the coming year.

Nottingham.—The Electric Lighting Committee of the Nottingham Town Council have prepared a report which will be presented to the Council next Monday. It embodies a full and lengthy report from their engineer, Mr. H. Talbot. The estimate of cost is land in Wollaton-street, £10,175; buildings, plant, and mains £34,580; total, £44,755. The committee strongly recommend that the site be purchased and the necessary plans and specifications put in hand, and as soon as consent of the Board of Trade is obtained that tenders should be invited. The system to be adopted is low pressure continuous three-wire distribution in conjunction with high pressure continuous current and motor transformers, the station to be for 15,000 8-c.p. lamps, plant for 10,000 8-c.p. to be first put down. The dynamos are to be specified at "so much water used per electrical horse-power at the terminals." Batteries for 1,000 8-c.p. lamps would be installed.

Heckmondwike.—At last week's meeting of the Heckmondwike Local Board, the Electric Lighting Committee's minutes were read and approved. They authorised a visit to view the installation at Morecambe, and to ascertain from the town clerk of [illegible] borough the terms upon which his Corporation had arranged to transfer their power to light the borough with electricity to a private lighting company. Mr. Redfern remarked that the committee did not appear to be making much progress with the scheme, and impressed upon them the necessity of making a report to the Board one way or the other as soon as possible. The Wholesale Co-operative Society would require the 500 lights which they had promised to take for their Heckmondwike shoe works by next September, or they would take steps to adopt an installation of their own. If the Board intended to go on with the work, it should be done at once, or it would be no use troubling any more about it. Mr. S. Wood (the chairman of the committee) replied that the committee were expediting the matter all they could and would soon be able to submit a report to the Board.

The Rhondda Valley.—In the localities of Cwmdare and Cwmpare, situate in the upper part of the Rhondda, where the Ocean Colliery Company have two large collieries, there have been hundreds of workmen's cottages lighted by electricity in the evening and morning for the past few months. The [illegible] generating the electric current is situated in the fan engine-house at the Dare Colliery, using the motive power of the fan engine. On Sunday evening the Independent and the Methodist chapels were lighted by the plant at the colliery, and the [illegible] gave absolute satisfaction. Since the chapels were opened [illegible] years ago they were lighted in the evening with oil, there being no gas mains in the district. Mr. Williams, electrician at the Ocean Collieries, informed the members of the chapels that the places of worship could be very well lighted by the electric current from the collieries at a cost not exceeding [illegible] annually, so the oil lamps were replaced by electric incandescent lamps, numbering about 25 in each chapel. The innovation caused considerable curiosity in the localities, and hundreds [illegible] place to see the light in the chapels. The members of the [illegible] chapel in the district have decided to have their place of worship lighted by electricity, and the oil lamps will be abandoned.

London Mains.—The Highways Committee of the London County Council, at their meeting on Tuesday, reported that they had considered a notice, dated 12th November, 1892, from the House to House Electric Light Supply Company, of intention to lay mains along two sides of Hereford-square. These mains will be laid in 3in. cast-iron pipes, and the proposed works appear to be unobjectionable. They recommend that the sanction of the Council be given to the works referred to, upon condition that the company do give two days' notice to the Council's chief engineer before commencing the works in any of the streets referred to in the notice; that no pipes of a larger diameter than [illegible] be used; that the street boxes shall be of the pattern approved by the Council, and that, as an additional precaution against accident through defective insulation of the mains, each of the street boxes shall be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover shall be efficiently connected to earth. The Kensington and Knightsbridge Electric Lighting Company has also given a notice, dated November 1892, of two short extensions of mains in Cromwell-road. The committee recommend that the sanction of the Council be given to the works referred to. The St. James and Pall Mall Electric Light Company has given an emergency notice, dated November 22, 1892, of its intention to substitute insulated cables for the existing bare copper conductor mains in Pall-mall, from [illegible] street to 6, St. James's-street. The alteration, which is very desirable, should be made in all cases as quickly as possible and the committee are of opinion that the company is justified in treating the matter as one of emergency.

Llandudno.—A proposal is being brought forward in Llandudno by Mr. W. Kingsland, A.I.E.E., for an electric railway along the Parade, on the spare space between the asphalte and the [illegible]. It is proposed to have a small station for generating the current by means of a gas engine and a dynamo machine, which would be put out of the way somewhere at the back, about Craigydon. The current would be conveyed underground to the trams, and by means of suitable connections be applied to the car as it moves along the rails. The current would be used at such a pressure that no shock could be received, even if the bare conductors were freely handled. It is proposed, in return for the concession to run the line, to light the Parade with electric arc lamps all the year round; with regard to the desirability of which there would be hardly two opinions. Of course the cars would be run during the winter as well as in summer, though necessarily not so frequently. This will doubtless add to the attractions of the place as a winter resort, besides being of the greatest service to residents at Craigydon, Little Orme, and Penrhynside. The facilities which the line will offer to residents and visitors at these places all the year round will, it is thought, be a very great consideration in its favour. The line will be single, with a crossing place at the middle, so that there will be two cars running on the line, starting simultaneously at each end, and passing each other in the middle. The speed will be about six miles per hour. A return ticket for the whole distance would be issued at 3d., or 2d. for the single journey, and 1d. for [illegible]. The cars would stop to take up or set down passengers at any point. One of the principal objections which is sure to be brought forward in connection with this scheme is anticipated by Mr. Kingsland. It is with regard to the danger to children and

others in crossing the line. Being anxious to know on authority what had been the experience at Brighton, he wrote to Mr. Magnus Volk, the proprietor In his reply Mr Volk says: "During nearly 10 years (10 summers, anyway) we have never injured one of our passengers in any way, we have never touched a child, and merely bumped one foot passenger, who, to avoid a perambulator, suddenly stepped against one of our cars." Mr Kingsland is right in anticipation of this objection, for a ratepayer writes to say he is sure any Board would be turned out which proposed such a "danger." It is very possible, however, that the proposal may not be so regarded by other ratepayers.

Brighton – At yesterday's meeting of the Corporation the principal matter upon the agenda was as to the electric light undertaking At the time of going to press it is impossible for us to receive the deliberations so that we can only give an abstract of the suggestions made by the Lighting Committee, which were to the effect that the King's road should be lighted up to 11 o'clock p.m. by arc lamps, and after 11 o'clock with incandescent lamps, at an estimated cost for arc lamps of £875, and for the incandescent lamps £337, a total of £1,212 per annum, this being £290 in excess of the present cost of gas The capital outlay of this lighting would be about £2 700 The extension of the works is immediately necessary to meet the increasing demand for the supply of electricity, and the new area to be fed was given in the committee's report, and the estimated cost of the mains to be laid, as £12,350. It was reported that the capacity of the present plant is very nearly reached, and that, considering the probable increase of business, they would be warranted in putting down two 300 h.p steam dynamos and two sets of storage batteries. This addition, if one of the large 200-h p. dynamos be held in reserve, will bring the capacity of the station up to 18,400 8-c p lamps burning at one time, which is more than double what can be safely supplied with the existing plant. More boiler power would be required for the additional plant The total estimated cost of the plant required is £5,730, and for buildings about £1,700 Altogether it is estimated that the extension of mains in the present area, and the additional mains in the extended area, the new house services, the additional plant, the extension of buildings and contingencies, requires a total expenditure of £35,000. With regard to the revenue of the current year, the following was given as an approximate statement ·

Generation of electricity	£1,745
Distribution	10
Rates and taxes	50
Managing expenses	695
Special charges	88
Total	£2,588

The total revenue was £4,917. 10s 9d. After the interest and sinking fund had been paid there would be a profit of £108 10s 9d In conclusion, the committee further recommended as follows "1. That application be made to the Local Government Board for sanction to borrow a further sum of £35,000 for a period of 30 years, for the purposes of the Brighton Corporation Electricity Works. 2 That the portion of the premises belonging to the Corporation and adjoining the electricity generating station on the south, shown on the plan submitted herewith, be appropriated for the purposes of the undertaking and that a proportionate part of the debt created for the purchase of such land be transferred to and charged upon the undertaking 3 That the committee be authorised to carry out the works described in this report and to obtain such contracts as may be necessary for the purpose" The Works Committee, in response to an application from the Lighting Committee, recommended that they should be empowered to put the latter in possession of the whole of the land recently purchased in Church street, the Lighting Committee to take over the debt created by the purchase of such land.

Mansion Lighting —Benmore, near Kilmun, Argyllshire, the residence of H J. Younger, Esq has recently been fitted throughout with electric light the installation having been supplied and erected by Messrs Ernest Scott and Mountain Limited, of Newcastle. The engine and dynamo room and accumulator house is situated about 120 yards from the mansion. The generating plant consists of a Priestman patent oil engine, capable of giving from 18 to 20 effective horse-power, driving a shunt wound dynamo of Messrs Scott and Mountain's improved type, capable of running 200 16-c p. lamps direct, or of charging a set of accumulators capable of running 170 16-c p. lamps for about four hours The building containing the machinery is of an ornamental description, constructed entirely of stone, the accumulator house being placed at the end of the engine and dynamo room, so that the accumulators are kept away from the machinery At the end of the engine room is placed a main switchboard, consisting of an enamelled slate base on which is mounted an automatic switch for automatically switching in and out the dynamo at the correct moment. A main charging and discharging switch is arranged so that the dynamo can charge the accumulators, discharge the accumulators through the lamps, running the dynamo and accumulators together or, if necessary, running the lamps direct from the dynamo; and another switch is also provided by which the oil engine can be started by simply switching the current from the accumulators on to the dynamo, which runs as a motor, and as soon as the dynamo has started the engine, the latter quickly acquires its correct speed and then drives the dynamo and commences charging the accumulators. This arrangement entirely prevents the necessity of pulling the flywheel round in order to start. An ammeter and a voltmeter are also provided. The current from the main switchboard is taken to the house by underground cables Six cables are laid in wood troughing, filled in with bitumen and covered with cement, the object in providing these six cables being to enable the last five cells of the accumulators to be switched into circuit from a distributing switchboard in the house The switchboard which is placed in the main hall, is mounted on an enamelled slate base in a handsome oak case with a glass front The whole of the house has been fitted up with the electric light, and there are altogether about 180 16-c p. lamps in the installation. The scheme of wiring adopted consists in using terminal boxes placed one on each floor, the whole of the cut outs for each floor being placed in the terminal boxes, and there being in no case more than six lamps on any circuit By this arrangement the whole of the cut outs are kept together and, in the event of a light going out, a new fuse can be immediately inserted without having to hunt about to find the cut-outs. The electroliers and electric light fittings were designed specially for Messrs Scott and Mountain by the Manto Manufacturing Company The result is exceedingly pleasing, and the fittings have given every satisfaction This very complete installation has been carried out under the supervision, and to the specification, of Mr W A. Bryson, consulting engineer, Glasgow, Mr M B Mountain, of Glasgow, having supervised, on behalf of Messrs. Scott and Mountain, the erection of the installation

Epstein Accumulators. The Epstein accumulators appears to be meeting with favour for traction work, for we hear that the Epstein Company have received an additional order from the Birmingham Central Tramways Company for six sets of the accumulators, each set consisting of 96 cells of the T 9 type The first sets supplied have been in regular use for three months, and the satisfactory results obtained certainly go to prove the efficiency of these cells for traction work A point which is of the utmost importance to tramway companies is that the maintenance of these cells has been undertaken at a low rate, one which, while advantageous to the tramway companies, is also stated to be equally advantageous to the accumulator company With the upkeep of the batteries low, the working cost of the accumulator traction would be less costly than that of the overhead trolley system, and as their use is especially suited for crowded districts where poles will not be tolerated, we should certainly feel pleased to find that the introduction of the accumulator cars is helped forward by the use of the Epstein cells. These are not of the pasted grid type, but formed of corrugated solid plates of lead The difficulty of the use of secondary cells for traction work has always been a question of maintenance the short life of the so-called "positive" plates. When a cell of the pasted grid type is first electrically formed or when the polarity of a plate is intentionally reversed, it is noticed that the formation begins at the edges of the plugs, gradually extending towards the middle, thus proving that those parts of the active material which are nearest the grid participate most in the action of the electrode, the action diminishing towards the centre of the plug It is, further, a well known fact that the action of any electrode begins in that plane where the electrolyte and the electrode meet During the discharge of a secondary cell sulphate of lead is produced, which necessarily tends to occupy a much larger space than either peroxide of lead or the spongy or finely divided metal, of which the plugs consisted prior to the discharge The loss of capacity, the scaling and short circuiting, the falling out of the plugs when the cell has been allowed to discharge below the critical point of P D. 1·8 volts), are thus easily explained The too long continued discharge produces an excess of sulphate, and this sulphate is not evenly distributed through the plug, but abounds at the edges and at the outer surfaces. Consequently parts of the active material have not only become more or less inert, but the outer layers of the plugs, endeavouring to occupy more space than is allotted to them, come apart from the inner, less sulphated layer, and scaling and short circuiting follow as a natural consequence The Epstein cells withstand treatment which would be destructive to other cells. The entire absence of paste in their construction offers in itself great security, but the fact that the plates are solid lead castings, and that the active material, which is formed by direct oxidation blends inseparably with the lead accounts for their leading advantages The plates being corrugated on both sides, with a solid web in the centre, are very strong, and cannot buckle, and the extensive surface thus presented renders it possible to reduce the number of plates per cell considerably, and therewith the risk of accidents, while at the same time a saving in space is effected It was with these cells that Prof Ayrton consented to make tests with a view to ascertain, not what the behaviour of the cells would be when used with care but what the capacity and efficiency would become when their treatment is "worse than it ought ever to be in actual practice." For this purpose the cells (of which over 100 charges and discharges have been taken by him) were frequently left discharged for many days at a time, for example for as many as 17 days; further, the rate of discharge was very high, while the limit in discharging was taken lower and lower until it latterly fell to zero, the very worst treatment possible. But as for detrimental effects they were conspicuous by their absence, the capacity had not decreased, the plates had not buckled or short circuited, and they looked quite good and not at all spongy. The following comparison is given of the cost of plant between overhead and accumulator traction with Epstein cells. Taking for an example a representative line about 6½ miles in length, with a service of 25 cars, having gradients varying from 1 in 300 to 1 in 21, the approximate difference in the cost of conversion into either the overhead or the accumulator system will be as follows · Overhead Converting 6½ miles double horse track, including laying and connecting to rails of return conductor, at £400 per mile, £2,600, 6½ miles of overhead structure, iron poles, conductors, etc., at £3,000 per mile, double track, £19,500; total, £22,100. Accu-

mulators: Accumulators for 25 cars, 2½ batteries per car (five batteries divided between two cars), of such capacity as to enable a five to six hours' run with one charge, £13,500; balance in favour of accumulators, £8,600. Besides this, there will be a saving in the cost of machinery at the central station, which in the case of the overhead system must have a sufficiently large output to supply the maximum current found to be required by the whole of the 25 cars at any one time, and must in addition provide continuously the power consumed in the losses arising from the different transmissions. According to measurements made on several overhead tramways in the United States, the efficiency of the entire system—viz., the proportion of the brake horse power on the car motors as compared with the indicated horse power of the engines at the generating stations—has been found to amount in some cases to only 25 per cent., and in no case to exceed 40 per cent. in everyday practice. Taking an average efficiency of 33⅓ per cent., it follows that the boilers, engines, and dynamos at the central station will have to be so designed as to give at least 3 h.p. for every 1 h.p. of the car motor. With accumulators, the central (charging) station need only be of sufficient magnitude to charge one battery or one battery and a fraction per car at a time, and as the loss in power arises from a smaller number of transmissions (steam engines through dynamos to accumulators), as against the additional losses in the overhead system (from dynamos through the overhead wires, motors, gearing, to driving axle), a considerable saving in the cost of plant can be effected with the accumulator system. With regard to the efficiency it has been found that in the most favourable case where overhead wires are in use about 70 per cent. of the indicated horse power of the engines is transferred to the motors, while on most of the roads the percentage is between 50 and 60 per cent. Allowing for the loss of 10 per cent. in the dynamos, the efficiency between these latter and the motors is therefore on an average about 60 per cent. Prof. Ayrton found the energy efficiency of Epstein accumulators to be 84 per cent., while such batteries, which were regularly discharged and recharged in even the short time of three hours, gave an average energy efficiency of 76 per cent. It is therefore expected that the total efficiency of a line worked by Epstein accumulators, taking into account the increased weight of the accumulator car, will be higher than if the same line were worked by the overhead system, and at the same time the relative cost of coal per horse power, for the reasons given above, will certainly be lower. Referring to the question of maintenance, practical experience has enabled the Epstein Electric Accumulator Company to enter into maintenance contracts with tramway companies at a very moderate rate per mile run. For instance, on a line similar in character to the one before mentioned, with gradients varying between 1 in 300 and 1 in 21, and with cars of a carrying capacity for 50 passengers, this rate will only be 1½d. per car mile, which rate, in the opinion of the Epstein Company, will not only be sufficient to reimburse them for the renewal, but will leave a fair margin of profit. With a smaller outlay for the installation, no interference with rails and road and existing traffic, absence of poles and wires, greater security in the working, and a cost of working certainly not in excess of the trolley system, it should not be doubtful that accumulators are destined to play a large part on all lines where electrical traction can be introduced.

PROVISIONAL PATENTS, 1892.

October 11.

16641. **An improved coupling for lightning conductors.** Joseph Lewis, 5, Great Winchester street, London.

November 21.

21136. **Improvement in shade carriers for electric light pillars and brackets.** Joseph Taylor, 9, St. Augustine road, Camden square, London.

21147. **Improvements in and relating to electric vehicles for use on roads.** Charles Riley Garrard and Thomas William Blumfield, 37, Chancery lane, London.

21169. **Improvements in regulating apparatus for electric arc lamps.** Julien Dulait, 28, Southampton buildings, Chancery lane, London.

November 22.

21193. **An improved method of producing zinc from blende by electrolysis.** Gunnar Emil Cassel and Fredrik Adolf Kjellin, 11, Southampton buildings, Chancery lane, London. (Complete specification.)

21243. **Improved method of forming junctions between electric light cables and electric lamps.** Francis William Webb and Arthur Moore Thompson, Holly Bank, Crewe.

21268. **Improvements relating to suspension devices, chiefly designed for electric incandescent lamps.** Stephen Porter and John Robert White, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

21273. **Improvements in and relating to electric clocks.** Martin Van Buren Ethridge, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

November 23.

21292. **An electric alarm for gill drawing frames as used for flax and other fibres.** Adam McMeekin and John Logan, Cogry Mills, Doagh, co. Antrim.

21339. **Improvements in electrical indicators and connections therewith.** Robert Henry Kettle and Charles Graham, *Beaumont House*, Castelnau, Barnes.

21348. **Improvements in the treatment of zinc produced by electrolysis.** William Wright and John Bumfield Hamond, 1, Quality court, Chancery lane, London.

21372. **Improvements in insulators for electric telegraph wires and other electric conductors.** Bessie Alice Jeannette Espeut, widow and executrix of the late William Bancroft Espeut, 24, Southampton-buildings, London.

21376. **Improvements in electrical resistances.** Henry Edmunds, 47, Lincoln's inn fields, London.

21377. **Improvements in electric conductors.** Henry Edmunds, 47, Lincoln's inn-fields, London.

November 24.

21435. **An electric automatic repeater cut-out.** James Ferrée and James William Ferrée, 72, Reedworth street, Kennington road, London.

21480. **Improvements in the means or apparatus for measuring electricity.** George Lee Anders and Walther Kruger, 10, Jeffrey's square, St. Mary axe, London.

November 25.

21506. **Improvements in electrical governors for marine engines.** Hugh Archibald Fergusson, 62, St. Vincent street, Glasgow.

21530. **Automatic electrical signalling on locomotive engines.** Joseph Atack, 105, New Park street, Blackburn.

21533. **Improvements in apparatus for measuring electric potentials and quantities.** Guy Carey Fricker, Lincoln's inn fields, London.

November 26.

21613. **Improvements in telephonic transmitters.** Alban [illegible], 15, Water street, Liverpool. (Complete specification.)

21621. **Improvements in and in the manufacture of incandescent lamps.** Demetrius Von Mito, 4, [illegible], London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

which was installed by Messrs. Paterson and Cooper, is rendered available at night for football matches by electric light, and these matches take place twice a week, to the great admiration of the visitors, and with very successful effects.

Atmospheric Electricity.—M. Hermite, nephew of the famous analyst, has been making some curious researches by means of small free balloons. Very light but strong self-registering instruments are mounted therein so that they will not break. M. Hermite has obtained some interesting results on the temperature at altitudes of three to five miles. An address card was attached to these balloons, some of which descended 100 miles or more from Paris. Observations by means of long copper wires are being made on the electric state of the atmosphere. An account of these researches was presented to the Académie des Sciences on the 20th ult., at which meeting also some results upon the construction of the Mont Blanc Observatory, by M. Janssen, were also submitted.

Niagara.—Electrical engineers will muster in force on the 14th to hear Prof. Forbes discuss "The Utilisation of Niagara." It is well-known that Prof. Forbes has been largely occupied professionally for some considerable time back on this the largest electrical and hydraulic engineering enterprise of the world, and what is now to be said will be listened to with the greatest attention. As a side detail, Prof. Forbes seems to have his own ideas on the subject of philology as well as engineering, and those who attend his lecture will hear the beautifully soft true Indian pronunciation of Niagara (as Neeagaara) instead of our snappy insular attempt usually given to the name of the falls. Sir Richard Webster, Q.C., M.P., will take the chair, and from the universal interest of this subject of the utilisation and transmission of the energy of Niagara Falls, we anticipate a full meeting at the Society of Arts.

University Extension at Plymouth.—Plymouth and District Students' Association (Cambridge University Extension) met at the Free Library on Thursday last week, when Mr. Thomas P. Treglohan gave a lecture on "Frictional Electricity." The lecture was specially prepared for students qualifying for the examination that will immediately follow the course of lectures now being delivered under the Cambridge University Extension Scheme, and which must be passed by all who desire to become affiliated students in science to the university. The lecture was well illustrated with diagrams, and at the close a number of questions relating to the mathematical part of the subject was given to, and satisfactorily worked by, most of the students present. Before the lecture, Mr. Cumings, one of the members of the association, exhibited and gave a detailed explanation of a Gramme dynamo-electric machine of his own construction.

Test of a Submarine Boat.—The new submarine boat invented by Mr. Baker was successfully tested in Lake Michigan, some distance south of Chicago, last Saturday, in the presence of two members of the Torpedo Board of the United States Navy. At 10 o'clock in the morning the vessel was towed a mile out, an electrical expert and an engineer being the only persons on board. On the first trial the boat failed to dive below the surface, owing to her machinery being out of order, but, upon additional ballast being secured, a second and more satisfactory trial was made. The officers of the Torpedo Board expressed no opinion with regard to the boat's performance. They will forward their report to Commodore Folger, the chief of the Ordnance Bureau. The boat was built at a secluded point on the Detroit river. She is 40ft. long and 14ft. deep, and cost about 3,000dol. When under the water she is propelled by electricity, and when on the surface steam may be used, generated from oil fuel. She can travel under the water at the rate of 10 miles an hour. On the top of the vessel is a small observation tower, through which the crew can reach the interior. The tower is closed by a screw cap, and is provided with windows. The air is obtained from tubes running on the surface of the water by means of an electrical device.

Appointment.—In consequence of a rearrangement [illegible] the headquarter staff of the General Post Office, London, brought about by the death of Mr. Edward Graves, [illegible] late engineer-in-chief to the department, the important position of chief technical officer to her Majesty's Post Office has been conferred upon Mr. John Gavey, of Cardiff. Since the year 1872 Mr. Gavey has held the position of superintending engineer of telegraphs for the South Wales district, and has resided in Cardiff for the past 15 years, during which time he has been closely indentified with the [illegible] and scientific life of the town. For several years [illegible] has been a prominent member of the Cardiff Naturalists' Society, holding the office of hon. secretary for three years and the presidency of the society in 1890. Mr. Gavey has served the town for some time on the Free Library and Museum Committee, and has also been a member [illegible] Technical Education Committee since the introduction [illegible] the Technical Education Act, a position for which [illegible] fessional acquirements rendered him especially fitted. [illegible] Gavey has taken great interest in the development [illegible] telephone in his district, and the present effective [illegible] of telephone trunk lines connecting the various [illegible] centres of South Wales and Monmouthshire, [illegible] erected under his supervision.

Placing Turnouts.—The rules for placing [illegible] "turnouts" on the double line spaces on a [illegible] track is the subject of an article in the *Electrical* [illegible] November 19 by Mr. W. E. Harrington, B.Sc., [illegible] the question mathematically and practically. He [illegible] geometrical diagram to calculate the distances, [illegible] following rules: 1. The number of turnouts [illegible] number of cars is one less than the number of cars [illegible] 2. The time consumed between turnouts must be the [illegible] through; if irregular, this time must be that required [illegible] the longest distance even if others are only a small [illegible] of this distance. 3. The time between two [illegible] turnouts is half that between cars. As to [illegible] turnouts, two cases should be considered: First, [illegible] certain number of cars are to be run for the [illegible] portion of the time, and extra cars for odd and [illegible] intervals, the turnouts should be placed to suit the [illegible] business; second, in the case of a line running an [illegible] number of cars—for instance, a heavy business at [illegible] times of the day—as the lesser number of cars are [illegible] nate to the greater number, the turnouts must be [illegible] to run the large number efficiently. The gradients, [illegible] thoroughfares, stoppages by level crossings, and [illegible] business must, of course, all be considered. The [illegible] matter of turnouts is exceedingly simple when [illegible] are known, but a tramway line cannot be run [illegible] unless the managers are conversant with these [illegible]

Welcome to America.—A letter to the [illegible] effect has been received by the Secretary of the [illegible] of Electrical Engineers from representatives of the [illegible] important American engineering societies: "[illegible] view of the probable attendance of many of your [illegible] at the Columbian Exposition, to be held at Chicago [illegible] year, we desire to assure you of the hearty welcome [illegible] awaits them on their arrival in New York from [illegible] fessional brothers of the American Society of [illegible] neers, the American Society of Mechanical Engineers, [illegible] American Institute of Mining Engineers, and the [illegible]

Institute of Electrical Engineers. The homes of these several societies will be open to such visitors as are duly accredited through the secretaries of their respective associations, and efforts will be made to facilitate the objects of their visit. Anticipating for ourselves much pleasure in carrying into effect the wishes of our constituent societies, and in looking after the interests of our visitors, we have the honour to be, very truly yours, Mendes Cohen, A. Fteley, and John Bogart (committee of the American Society of Civil Engineers); J. F. Holloway, Henry R. Towne, and S. W. Baldwin (committee of the American Society of Mechanical Engineers); F. G. Spilsbury, F. S. Witherbee, and C. Kirchoff (committee of the American Institute of Mining Engineers); Franklin L. Pope, Jos. Wetzler, and Francis R. Upton (committee of the American Institute of Electrical Engineers). By order of the committees, C. Kirchhoff, secretary, New York."

Electrical Fire Risks. — With reference to the solicitor's letter to the *Times* on insurance risks, which we quoted the other day, the *Fire Insurance Review* says: "From the record of some recent fires, we should say that the sooner the public are made aware of the fact that the average gasfitter or plumber is not by virtue of his calling fitted to take charge of the installation of the electric light, the better for both the householder and the fire offices. Meanwhile it may be as well to know that the installation of the electric light, if unaccompanied by a survey and permission by the fire office to use it, does constitute an extra risk, and imperils the security of the assured to a very great extent. And for this special reason, that whilst an electric light fire generally consumes the evidence of its guilt, yet if a fire does occur in a house where an electric installation has recently been made, it will be found exceedingly difficult to prove that it was not the electrical installation which caused it. We would suggest that all fire offices print in large letters in their Christmas notices, that where installations of electricity have been made, the same must be declared at once to the fire office interested. We know ourselves of one large house in the North of England where 1,100 lights are at work, or may be worked, and we also know that the fire insurance company interested has never called for a report of an electrical engineer on the installation. We cannot help thinking that the fire office itself is very much to blame in the matter—that is to say, if it is aware that the house is lit by electricity." It is really, we think, part of the duty of the electrical contractors, and we strongly advise them in every case to let their clients know of the necessity for the proper notice to the fire office.

A New Cable-Making Machine.—A cable-making machine of a new type has been recently completed by the New England Butt Company, of Providence. It is for New York manufacturers, and was designed, says the N. Y. *Electrical Review*, to meet the growing demand for telephone cables to be laid underground. The machine is [illegible]ft. wide and 56ft. long, and is composed of five heads, revolving in different directions and driven by gears on a shaft extending the entire length of the machine. Upon each head is placed the desired number of reels containing the wire, which, preparatory to the cabling process, is covered with two layers of paper. Each layer of paper is bound on the wire, and two wires are then "twinned," or twisted together. On the first head are reels for making a cable of [illegible] wires, the wires unwinding from the reels as the head turns and passing through an aperture at the centre of the head. The other heads have similar reels of twinned wire, and increase the size of the cable by adding wires until the cable is 2½in. in diameter, and is composed of 120 wires. As it leaves each of the heads the cable is bound together, and when completed is covered with jute, hemp, flax, or cotton. Passing from the last of the series of heads, it goes around a wheel 5ft. in diameter, and is then wound on a drum and is ready for the treatment preceding its encasement in lead pipe. Attached to the machine is a measuring device. The cable rests on a large pulley, and is held there by the weight of a loosely-mounted circular block. As it passes through the machine it turns the pulley, which is geared to plates or dials on which are figures indicating the number of feet of cable that have been drawn over the wheel. The capacity of the machine is from half a mile to a mile per day, and its advantage is in completing the cable at one operation, and avoiding injury to the wires by frequent handling and bending, which has been the defect of previous machinery for making telephone cables.

Multitubular Accumulator.—M. D. Tommasi sends us some particulars of his multitubular accumulator which will be found interesting. This accumulator is characterised by electrodes enclosed in a tubular envelope or metallic sheath, or in any rigid or elastic insulating material, such as celluloid, ebonite, indiarubber, etc., perforated with a large number of small holes. In the centre of this sheath is placed a core of lead or alloy, or of other metal suitable to serve as conductor to the current, and in contact upon each of its surfaces with a coating of oxide of lead preserved from falling or disintegration by the perforated envelope which imprisons it. This arrangement has the double advantage of doubling the amount of active material, and thus the capacity, of the accumulator for equal weight. The cell is therefore light, of great capacity, and small volume. The charging current can be calculated at 5 to 6 amperes per kilogramme (2 to 2½ per pound). The discharge can be varied from 1 to 4 amperes per kilogramme (say, ½ to 2 per pound) of electrodes. It should be stopped when the voltage falls to 1·7 volts. In cases where sudden variable discharges are necessary the Tommasi accumulator can bear 6 to 8 amperes per kilo (say, 2½ to 3½ per pound) of electrode without inconvenience. The electrical constants of this accumulator are as follows:

Initial E.M.F.	2·4 volts
Capacity per kilogramme of electrode...	20 ampere-hours
„ per pound of electrode........	9 „
Efficiency in quantity	95 per cent.
„ in watts	80 „

In announcing a capacity of 20 ampere-hours per kilogramme, M. D. Tommasi has adopted mean discharge, which may vary between one and three amperes per kilogramme of electrodes. It is evident that by employing a lower mean the capacity would be increased. To obtain a comparative idea as to the large capacity of the Tommasi cell, it is sufficient to compare it with known types used in lighting and traction, and M. Tommasi claims that the capacity of his accumulator is from three to five times that of the best known types. The simplicity and strength of the construction of the Tommasi cell are great points in its favour, and we doubt not that it will render considerable service in practical work. We believe a company has been recently formed in Paris to manufacture this accumulator, of which great things are expected by those interested therein.

Electric Railway Signals.—A very necessary reform in railway fog signalling is alluded to by Mr. J. Stones, of Smethwick, in a letter to the Birmingham *Daily Post*, and as we have already given some prominence to attempts in this direction, it may, perhaps, be well to give this letter in full. Experiments were undertaken at King's Cross, but were dropped, we fancy, through quarrels between the

inventors. There is no reason for not continuing the research after this much desired perfection, with reference to which Mr. Stones thus writes: "It appears to me that an improvement could be made in the present system of signalling trains by having a telegraphic instrument fixed on the engine. This could be communicated with the signal-box by laying a wire alongside the rails, loose, in V-shaped insulators, and fixing a pulley on the engine or tender at sufficient height to pick up the wire as the train travelled. The return, or earth wire, need only be fixed to any part of the engine, and the current would pass through the wheels to the earth. If this was done, the driver, or brakesman, would be in constant communication with the signalman. Of course, the line would be divided into sections, and when the train entered upon any section the brakesman would ring the bell in the signal box, and get a reply 'train on line' or 'line clear. This would be more satisfactory to the driver than seeing a signal 'off,' because he would know that he was getting proper attention, and if he got no reply to his 'bell' he could pull up the train and see if the signalman was dead or asleep. There would also be a great advantage in this system during fogs, as it would not be necessary to see any signals along the line at all, and by insulating the wire, say, at 500 and 200 yards from every station, the driver would know exactly where he was, and could pull up the train at the platform without lights as well as with them. It is well known that during a foggy day the trains are altogether disorganised as regards keeping time, and when a fog comes on suddenly, no matter how well the thing is managed, it must take time to get the fog-men along the line, and while they are 'fogging' they must be neglecting some other duty." The practical difficulties are great, no doubt, but we cannot think that the inventiveness which has overcome so many obstacles can rest satisfied with the periodic dislocation of our traffic which occurs every year in the winter months.

Electro-Metallurgy. Mr. J. W. Swan lectured at the Midland Institute at Birmingham, on Monday, on the subject of "Electro-Metallurgy." The lecture was well illustrated with lantern experiments and a collection of specimens, including a reproduction of the famed Milton shield by Elkington's, together with map and picture engraving electros. Mr. Swan pointed out how large a position Birmingham had taken in the development of electro metallurgy, quoting the names of Elkington, Mason, Woolrich, and Gore. He went through, in an interesting manner, the history of the development of electroplating. Daniell's battery was not invented till 1836, and there could be no question that it was this invention that directly led the way to electrotyping. In the same year, De la Rue observed that the copper coating produced in Daniell's battery could be stripped off. In 1839, Jacobi, and Spencer, and Jordan independently published papers in which the artistic use of the electrolytic copper deposit was proposed. Long before this time electro gilding and electro-silvering had been done in an experimental way in the laboratory, but nothing of a practical kind had resulted. To develop the abstract scientific fact into the useful art required that combination of scientific knowledge with practical faculty and insight which Birmingham had so often produced, and which was supplied in this case by Elkington and Mason. "Ah," said Daniell on one occasion, "I have let two or three fortunes slip through my fingers. I have had all the labour, and those Birmingham people are getting all the profit." Precisely parallel was the case of Faraday, who left to Woolrich (another Birmingham man) the honour and the profit of giving practical effect to his discovery of the principle of the convertibility of motive power into electric current. Having illustrated the process of electro-deposition by experiments and views, the lecturer pointed out that the characteristic of an electrotype was extreme fineness. It was this feature that had given so great an advantage over casting in the reproduction of elaborate and artistic metal-work, that had, in fact, led to the creation of a new art-metal industry, in which masterpieces of chasing and engraving, both ancient and modern, were so perfectly reproduced that it was sometimes difficult to distinguish the original from the copy. The lecturer explained the processes of electroplating, and alluded to the plating by iron of engraved copper plates for maps—when used the iron could be dissolved and the plate recoated. The invention of the dynamo produced the most astonishing growth, and the refining of copper by electricity now produced between 30 and 40 thousand tons of copper a year. Aluminium was reduced in price to 2s. a pound by the same means. Mr. Swan then described the Thomson and Benardos systems of electro-welding, Birmingham having a special interest in the latter process. Concluding, the lecturer drew a picture of expected progress in the future, and, on the motion of Councillor Martineau, was awarded a hearty vote of thanks.

Durham College of Science.—On Monday the foundation-stone of the new wing of the Durham College of Science was laid by the Earl of Durham in the presence of an assembly of professors, scientific men, and local celebrities the list of whose names occupies half a column of an ordinary newspaper. After laying the stone in the usual manner, the Earl of Durham distributed the prizes. He hoped the prize giving would be all right. When he was a boy he at first thought the proper thing to do was to work, but that impression did not last long. He obtained a prize at the end of the first half, and he did not think he ever got another. His interest in geology was confined to putting stones in the keyhole of the classroom door and watching the efforts of the master in trying to get them out. This did not add to his studies. He hoped the students would always enjoy themselves in their work, and he wished them success. The students present thereupon sang "For he's a jolly good fellow." Other speakers followed, and letters of regret were read from Lords Armstrong and Ravensworth. At the dinner in the Assembly Rooms, Lord Durham proposed "The College of Science." He confessed his absolute and entire ignorance of science, his profound admiration and awe of professors and experts, and his readiness to believe anything they told him except that he could fly or be made young again. All the professors in the world could not make him believe he should become a young angel. But he trusted he was sufficiently intelligent to appreciate the advantages that science had brought. Largely, through efforts of the men of Tyneside, students had facilities for study that George Stephenson had not, and, as Stephenson said, the mistakes of young mechanics who thought they had hit upon some great discovery would be avoided by study and reading of books. The progress during the Victorian era had been so great that most people are prepared, with a few reservations, to receive not incredulously the announcement of almost any discovery. He felt the college had a glorious future before it, and although he believed that our progress had been hitherto made more by muscle than intelligence, he looked to the college to aid in the altered state of things, in adding to the wealth, glory, and honour of the British Empire. Prof Garnett, in reply, alluded to the success of the college, stating that in the last two years the expenditure had increased twofold and the number of students and professors still more

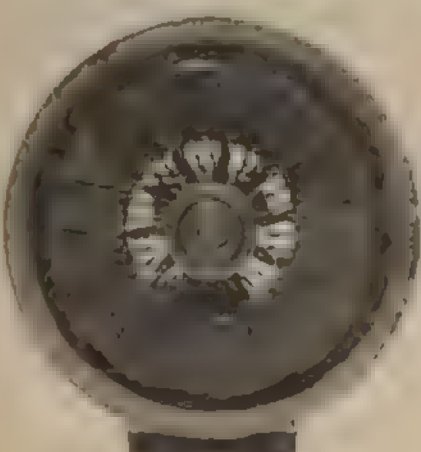
The most important section was the George Stephenson Engineering Department, for which one lady had presented a testing machine, and another a bust of Stephenson. He alluded to the progress of engineering education in the Yorkshire College and at Bristol, and now the engineering department at Durham would be one of the best equipped in the kingdom. Councillor W. Robinson replied on behalf of the Durham County Council, promising support; and Mr. Robert Thompson, president of the North-East Coast Institution of Engineers and Shipbuilders, also congratulated the college on their addition, and hoped the laboratory would also soon have a quadruple-expansion steam engine. The health of the chairman was then pledged with applause. The management of the college is greatly to be congratulated on the great progress which has necessitated the extension.

Zurich.—The installation of electric supply at Zurich has met with very satisfactory success. The installation was designed for a first supply, by high-tension alternators with transformers, of 10,000 16-c.p. lamps, to be subsequently increased to 20,000. There are, besides, 130 arc lamps for public lighting from the railway station to the lake. The generating power is obtained from hydraulic power—viz., 590 h.p. by two high-pressure turbines actuated by high-pressure water, 340 h.p. by two reaction turbines actuated by ordinary water power. There are also two steam engines of 230 h.p. in reserve. In practice not more than two-thirds of the incandescent lamps are alight simultaneously, even at the time of maximum in the winter, when, moreover, the number of arc lamps on the lake is reduced to half. The actual generating power required is about 533 h.p. The electric station constitutes a part of the pumping works. The arrangement of machinery is peculiar. The two high-pressure turbines provided with automatic regulators drive the four alternators on the same dynamo shaft to which the main shaft, by gearing of 1 to 3, transmits additional power from the reaction turbines or the steam engines. By means of friction couplings, the dynamo shaft can be worked in three parts, jointly or separately—two parts with high-pressure turbines with accumulated hydraulic energy for night service, and one part with the reaction turbines or the engines for day service. The alternators give, at 2,000 revolutions, 100 amperes at 2,000 volts each, or a total of 800,000 watts. They are excited by two small high-pressure turbines, driving two dynamos of 30 h.p. on the same shaft at 400 revolutions. The main and subsidiary cables are designed for a supply of 20,000 incandescent lamps. The primary cables, laid in a brick channel 2ft. below the surface, consist of four concentric high-tension (2,000 volts) cables, 40 millimetres square in cross-section, from the central to the distributing station in the centre of the town. The distributing station (2,420 yards up the river) consists of a masonry hut, 20ft. by 10ft., from which radiate the secondary mains, also laid in brick channels, leading to 18 transformer stations; these being circular iron boxes 3ft. 3in. diameter and 9ft. 10in. in height, containing altogether 44 transformers, which convert the high-tension current of 2,000 volts into low-tension currents of 100 to 200 volts for both house supply and street lighting. Both the primary and secondary cables are composed of single insulated copper wires, varying between 25 and 250 square millimetres (0·039 to 0·387 square inch) in section, with a double lead covering. Three secondary mains are always laid in one brick channel, the centre cable being for safety connected to earth in all transformer stations. The arc lamps for street lighting are mounted on standards 23ft. to 26ft. high, placed at equal distances apart of about 197ft. The sections of the copper cables are calculated from the formula $Q = \frac{2\,l \times J}{60 \times E}$; Q being $> \frac{J}{2}$, in which Q is the section in square millimetres, l the distance from the transformer in metres, J the current in amperes, and E the loss of tension in volts; a margin of 20 per cent. being added, and the sections being rounded off to current dimensions, between 25 and 250 millimetres square as mentioned above; whilst sections between 350 and 500 millimetres square are formed by combining smaller sections. The loss of energy being 5 per cent. between the dynamos and transformers, and 7 per cent. between the transformers and lamps, the energy of an incandescent lamp of 60 watts is reduced to 53 watts, or 0·26 ampere; and that of an arc lamp of 900 watts to 791 watts, or four amperes, at the point of consumption. The guaranteed efficiency of the transformer is 95 per cent. when fully, 92 per cent. when one-half, and 86 per cent. when one-quarter, loaded; and the loss when running unloaded is not to exceed 3 per cent. of the total capacity, which is 20,000 watts for each transformer. The 44 transformers therefore have a total capacity of 880,000 watts, sufficient for a maximum supply of 15,000, 18,000, or 20,000 lamps, according as the whole, three-fourths, or two-thirds are lighted simultaneously. The cost of installation designed for 10,000 incandescent and 130 arc lamps, including the electric machinery and distribution, but exclusive of the building, hydraulic machinery, and steam engines debited to the water works, is £48,560—equivalent to £628 per arc lamp of 900 watts, including standard and lamp—and about £4. 3s. per incandescent lamp of 60 watts. The total annual working expenditure, including interest and sinking fund, is £12,000; of which £3,480, for the 130 arc lamps (235,600 hours), and £8,520, for 10,000 incandescent lamps (5,000,000 hours)—being about 3·6d. per arc lamp (twice as dear, but five to ten times as much light as gas), and 0·4d. per incandescent lamp per hour. Hence the rates fixed for the supply of private incandescent lighting, based on a price of 0·76d. per unit, vary from 8d. to 4·25d. per lamp per hour, the mean being 0·6d. per lamp per hour for 1,000 hours, exclusive of the first cost of lamps and fittings and of the wear and tear, which amounts to about 0·05d. per incandescent lamp, and 1d. per arc lamp per hour. The rates include an annual fixed meter charge of 8s. for each lamp. These rates are 20 to 30 per cent. higher than those charged for the gas supplied by the Corporation gas works, and were so fixed with a view to protect the latter against injurious competition. The rates charged for electric lighting in other Swiss towns are very similar to those of Zurich—*e.g.*, at Lausanne, 0·72d. plus an annual charge of 36f.; at Vevey-Montreux, 0·42d.; at Geneva, 0·5d. per lamp per hour; while at Lucerne, a fixed charge of 16s. is made per 10-candle lamp per annum. The receipts from the 130 arc and 10,000 incandescent lamps are £14,640 per annum; the net surplus, after allowing for interest and sinking fund, is £2,640; and the total return on the capital expenditure of the electric installation, properly speaking, is 13·6 per cent. The special committee appointed by the Corporation recommended the erection of the installation proposed by the Oerlikon Works, near Zurich, which accordingly supplied the electric machinery; while Messrs. Escher, Wyss, and Co., of Zurich, furnished the hydraulic machinery; Messrs. Sulzer Bros., of Wintherthur, the steam engines; and Messrs. Berthoud, Borel, and Co., of Cortaillod, near Neuchatel, the cables, standards, arc and incandescent lamps, transformers, and accessories. These particulars are taken from a paper by Mr. Charles Du Riche Preller, on "The Zurich Water and Electric Works," in the selected papers of the Institution of Civil Engineers.

SIR DAVID SALOMONS'S FREQUENCY-RAISING MOTOR.

The greatest interest was manifested at the meeting of the Institution of Electrical Engineers last week over Sir David Salomons's new machine for obtaining a high frequency alternating current from any ordinary direct current. We were able in our last issue to give the first public description of this machine that has been issued, as correct and full as the short time at our disposal allowed; one clerical error will have been noticed, which we take the opportunity, in giving this fuller description, to correct—namely, that the "3,000 revolutions giving one million 'revolutions'" spoken of should, of course, have been "3,000 revolutions giving 'one million alternations' per minute.

Sir David Salomons's Direct-to-Alternating Motor Transformer.



Armature half.

The machine is the outcome of an ingenious idea. "Why could I not," said Sir David Salomons to himself, "construct an ordinary continuous current motor which should drive on the same disc an alternating current machine having an enormous number of poles? I should then obtain a low-tension alternating current of great frequency, which could be transformed up by an ordinary oil transformer and rival Tesla's current." This was the generating idea, and it has been carried out in an exceedingly ingenious manner by Sir David Salomons and Mr. L. Pyke. Mr. Pyke, as is well known, has lately made a speciality of high tension work, and his oil transformers, condensers, and induction alternating machines are interesting pieces of work in the little-explored field now associated with the name of Tesla. The details of the proposed machine having been discussed between them it was soon seen that to obtain the frequency demanded, of a million alternations per minute, a machine would be needed of considerable diameter, even for the smallest output. The idea then occurred to have both the field magnets and the armature of the continuous-current motor which was to act as driving power equally capable of rotation in opposite directions—a speed, each of 1,500 revolutions would then mean a total passing speed of 3,000 revolutions per minute. To obtain a million alternations, 360 reverses per revolution were needed, and a little calculation and trial showed that this could be done quite easily with a

Field magnet half.

ring of 1ft. in diameter only to form the alternating machine. By suitable careful arrangement the current which passed into and drove the motor was made to supply also the alternating current field magnets, and the final current thus yielded by the little alternator, though greatly reduced in quantity, is of the frequency of 1,000,000 per minute. Seeing that with Tesla's machine, which had to be driven by belting, and was 3ft. in diameter, an initial frequency of only about 300,000 per minute was given, it is seen that to obtain a frequency of 1,000,000 with a machine only 1ft.

in diameter, and one, moreover, that drives itself, a very neat little problem in high-frequency currents, more especially for experimental purposes, has been solved.

The appearance of this little machine is shown in the reproductions from the photographs. It is built in two halves, which are quite unattached (except through magnetic force), each half being capable of spinning on long bearings, from which the disc overhangs. The two are shown separated in one photograph, and complete, as in use, in the other. Taking the direct-current field magnet side first, it will be seen that there are two field magnets presenting flat sides to the opposite disc.

The brushes are mounted inside the machine upon these field magnets, separated therefrom by blocks of ebonite. The current comes in at two rings on the spindle, passing through the hollow spindle to the brushes. The current used is eight amperes at 100 volts continuous current. So much for the inside of the first disc. The outside of this disc consists, as shown, of a ring of soft iron, separated from the field magnets inside by a stout ring of ebonite. This iron ring is 1ft. in diameter, and is ploughed out in grooves, 10 to the inch—a total of 360 poles. These poles are wound exactly as for alternating-current field magnets—alternate north and south poles, wound Ferranti fashion, with No. 20 treble-insulated copper wire, made specially for the purpose. The windings are connected, two-and-two in series, and the whole of the sets are in parallel, the ends being joined together and connected in shunt to the inside motor brushes. They are thus in parallel with the motor on the 100-volt circuit, and when the current is on there are 360 alternate north and south poles.

Now, turning to the second disc, shown in the photograph beside the first. This disc contains, inside, the armature of the direct-current motor, and outside the many-pole alternate-current armature, as the first disc contains the fields. The armature of the motor inside the disc is in the form of a flat Gramme ring, and is connected by a commutator in the usual way to the brushes. When current is turned on, the reaction of course turns to drive the armature round, but the field magnets being also free they also revolve in the opposite direction. A speed of 1,500 revolutions a minute each produces, as we have said, a total of 3,000 revolutions.

The armature of the 360-pole alternator is mounted, in the same way as the field magnets, on the outside of the disc, and the revolution produces an alternating current in the wires of this armature. Eight amperes continuous current is put in at one end at 100 volts, and half-ampere alternating current is taken out at the other at 100 volts, but at a million reversals per minute. The efficiency, it will be seen, is not very high, being $\frac{1}{16}$th, or 7 per cent., the balance being all absorbed in heating and friction; but half-ampere is sufficient to experiment with, and Sir David Salomons thinks that he eventually can obtain $1\frac{1}{2}$ amperes or more.

The current so obtained is now passed into an oil transformer, which transforms the current from 100 volts up to 100,000 or so. The machine has been run off the Westminster Company's mains, and 1,000 1ft. vacuum tubes in series have been lighted by this means. Sir David Salomons has also taken the current into his body without dangerous effects, and tubes have been lighted without other connection by the hand.

So far we seem to have a distinct advance in the interesting subject of the production of vibratory currents, by the manufacture of this highly ingenious combination. There remains two questions to discuss, one of which we hope to see satisfied experimentally. The first is the lighting efficiency. Eight amperes at 100 volts will light about 16 ordinary 16-c.p. lamps. By the Salomons directo-alternator the current will light 1,000ft. of tube. We might take 1ft. of tube at $\frac{1}{10}$th c.p. The 1,000ft. would in that case (which we do not vouch for as a correct valuation) give 100 c.p., as against $16 \times 16 = 196$ c.p. on the usual system, or only 50 per cent. There is not much to be gained here therefore. But we are, of course, only at the experimental stage. Seven per cent. efficiency for the motor leaves a large margin, and the luminous efficiency of the tubes may be raised—who knows? At any rate the investigation is of the greatest scientific value, and will no doubt be productive of good results.

The second point is more alarming. We have no wish to frighten Sir David Salomons, but we do not wish to have one of our most enthusiastic experimentalists "hoist with his own petard." Testing with his own body pressures like 100,000 volts are all very well with small currents. No sooner is contact made than the E.M.F. falls at once and is wiped out. But with larger currents this may not be quite so quick in happening, and—well, we give the same advice as we gave to Prof. S. P. Thompson: try it on a calf first.

The great difficulty experienced with these high-tension vibratory currents is to insulate them. No ordinary wire will hold the current, which prefers to excite electrostatic effects on surrounding molecules. We congratulate Sir David Salomons on the interesting result of his idea, and also his earnest coadjutor, Mr. L. Pyke, on the outcome of their endeavours.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

VI.—OHM'S LAW AND THE ELECTRIC CIRCUIT.

(Continued from page 567.)

Heating Effects of the Current.—The resistance of all metals rises in proportion to the rise of temperature, the only exception being carbon, the resistance of which falls in proportion to its rise of temperature. For copper the increase of resistance is about one fifth of 1 per cent. for every degree F., or about three-eighths of 1 per cent. for every degree C.; suppose a copper conductor at an atmospheric temperature of 65deg. F. has a resistance of one ohm, then at a temperature of 95deg. F. its resistance would be $1 + 1 (30 \times \cdot 002) = 1 + \cdot 06 = 1 \cdot 06$ ohms. With gutta-percha, the resistance falls as its temperature rises, and this is the case with liquids. It was stated that there is no material that offers no resistance to a flow of electricity, and it was also stated that energy was spent when a current was forced along a conducting path against the resistance of the path. This energy is wasted on the conductor, and appears in the form of heat, the heat energy being exactly equal to the amount of electric energy that produced it. When a unit of current is forced through a unit resistance, one erg of work is done, and to do this requires one unit of difference of potential. When a mass falls through a difference of level the work done is measured by the weight of the mass multiplied into the difference of level or distance through which it falls; similarly with electricity, the difference of potential corresponds to the distance, and the quantity of electricity corresponds to the weight of the mass: hence difference of potential multiplied by the current will likewise measure the electric work done. One ampere flowing for the space of one second under an electrical pressure of one volt will therefore do $\cdot 1 \times 10^8 = 10^7 = 10{,}000{,}000$ ergs of work per second, because one ampere $= \cdot 1$ of a C.G.S. unit, and one volt $= 10^8$ C.G.S. units, 10^7 ergs per second = one watt, hence one watt is the practical unit of electric energy. So that we have

$$\text{amperes} \times \text{volts} = \text{watts};$$

746 watts make 1 h.p., therefore we may measure electrical power by multiplying the pressure in volts by the current in amperes, and dividing by 746, or

$$\frac{\text{volts} \times \text{amperes}}{746} = \text{horse-power.}$$

The output, or capacity, of dynamos is usually reckoned by kilowatts—a kilowatt signifying 1,000 watts—thus a dynamo designed to work at 110 volts pressure, and to give a maximum current of 500 amperes, is said to have an output of $\frac{110 \times 500}{1{,}000} = 55$ kilowatts; now, since 746 watts equals 1 h.p., therefore one kilowatt is, roughly, equal to $1\frac{1}{3}$ h.p., or 1 h.p. is equal to three-quarters of a kilowatt.

In the same way as steam power is sold or measured by horse-power hours, so electrical power is sold or measured by kilowatt-hours — one kilowatt-hour being named a

Board of Trade supply unit. One kilowatt-hour, or briefly, one "supply unit," is defined by the Board of Trade to signify 1,000 watts of electrical energy acting for the space of one hour. Hence one "supply unit" = 1,000 amperes flowing under a pressure of one volt, or 100 amperes under a pressure of 10 volts, or 10 amperes under a pressure of 1,000 volts, or generally 1,000 volt-amperes, for the space of one hour.

The amount of electric energy that is spent or wasted in the conducting wires is evidently found by multiplying the current that is flowing by the difference of potential that there is between the ends of the conductor, for this difference of potential measures what is technically called "drop" of potential, and signifies the pressure that is absorbed or lost in forcing the current through the resistance of the length of conductor. According to Ohm's law, volts = amperes × ohms, or E = C R, and energy wasted in the conductor is "drop" in volts × amperes, or E C, therefore, substituting the value of the volts, or E, we have energy wasted = (amperes)² × ohms, or $C^2 R$. Hence the energy wasted in the form of heat in a conductor is obtained by multiplying the square of the current by the resistance of the conductor.

The amount of heat energy generated by the flowing of the current through a conductor can be easily calculated. By inserting a coil of German-silver wire of known resistance in a bath of paraffin oil, and passing a known current through the wire, the heating effect will be shown by the rise of temperature of the oil. From numerous and careful experiments made, it is found that multiplying the electric energy wasted in the wire by the number ·24, gives the heating effect of the current per second in heat units, or calories, hence we have the following formula:

$$H = C^2 R t,$$

where H = calories = number of grammes of water raised 1deg. C., and t = time in seconds.

It is thus seen that the energy wasted is proportional to the square of the current, and directly to the resistance. The rapidity with which a substance dissipates or throws off heat is named the emissivity, and the heat generated in a conductor should be thrown off as quickly as it is produced there. The emissivity depends on the cooling surface, and this is measured by the circumference of the wire multiplied by its length, since circumference is proportional to diameter, hence the cooling surface of a wire is proportional directly to diameter. But the current that a wire will carry is proportional to the square of the diameter, since double the diameter gives four times the area, and therefore four times the current can be carried. The resistance is now only one fourth of what it was before, so that the electrical energy wasted by a wire of double diameter is $C^2 R = 4^2 \times \frac{1}{4} = 16 \times \frac{1}{4} = 4$ times what would be wasted in a wire of unit diameter, each wire having the same current density. We thus see that while the heat energy generated is fourfold, the cooling surface is only twofold, consequently the larger wire must become much more heated than the smaller wire. So the smaller a wire becomes, the greater is the current it will carry in proportion to its area; and the larger a wire becomes, the less is the current it will carry in proportion to its area. For example, suppose a wire of ½in. diameter will carry 400 amperes without overheating, it will be found that a wire of 1in. diameter carrying its proportional current—namely, four times 400, or 1,600 amperes—would become much hotter than the first, and a wire of ¼in. diameter, carrying 100 amperes, would become much cooler. The quantity of current per unit area is the same—that is, the current density, as it is called, is the same for all three wires; the explanation lies in the fact that the cooling surface is proportionally largest in the thinnest wire, and smallest in the thickest wire. Divide the 1in. circular wire into four circular strands or parts, each having one-fourth the sectional area of the solid wire; the cooling surfaces of the four stranded and one solid conductors will be in the ratio of $\sqrt{4} : 1 = 2 : 1$, because each strand will have one-half inch diameter, and four times one half equals twice one.

If this same solid conductor be divided into nine strands, each having one-ninth of the total sectional area, then ratio of cooling surface, as compared with the solid conductor, will be $\sqrt{9} : 1 = 3 : 1$; so that the cooling surface in this case will be trebled. The ratio can be at once obtained for any number of strands, putting the solid conductor at unity and taking the square root of the number ($\sqrt{n}$) of the strands for the stranded conductor.

We are now in a position to calculate out the temperature to which a given conductor will rise when a given current is sent through it, and by fixing this temperature at a safe limit, which must not be exceeded, we can then get at the greatest current that can flow without raising the temperature of the conductor beyond this fixed safe limit.

A wire which would become heated to about 24deg. C. or 75deg. F., while at atmospheric pressure, would, with the same current flowing through, become red hot when the pressure is reduced to, say, $\frac{1}{1 \cdot 7 \times 10^6}$th part of an atmosphere, thus proving that far more heat is conveyed away by convection than by radiation. The latter pressure is somewhere about that which remains in an incandescent lamp when so much air is exhausted that it may be said practically to be a vacuum.

The emissivity of copper, or the rate at which heat is dissipated from its surface, is ·0003 of a calorie per second for every square centimetre of exposed surface (one calorie being the heat necessary to raise one gramme of pure water 1deg. C.), for every difference of temperature of 1deg. C. between the wire and surrounding bodies. Hence the total heat emitted = ·0003 T S calories per second, where T = difference of temperature in degrees C., and S = exposed cylindrical surface in square centimetres. It has been shown that the total heat generated in the wire is expressed by ·24 C^2 R calories per second, where C = the current in amperes, R = resistance in ohms; and since the heat emitted or dissipated should be equal to the heat generated, therefore ·0003 T S = ·24 C^2 R, or

$$T = \frac{\cdot 24\, C^2 R}{\cdot 0003\, S} = \frac{800\, C^2 R}{S}.$$

So that multiplying the electric energy wasted in the wire by 800, and dividing by the square centimetres of exposed surface, will give the number of degrees C. of temperature the wire will be raised above the temperature of the atmosphere.

We have also, $C = \sqrt{\left(\frac{\cdot 0003\, T S}{\cdot 24\, R}\right)}$.

This formula gives us the maximum current a wire may carry, so that its temperature shall not rise more than T degrees C. above that of the atmosphere. In practice conductors should not be heated more than 50deg. C. or 90deg. F. above the atmosphere; so that we deduce the following formula:

$$C = \sqrt{\left(\frac{\cdot 0003 \times 50 \times S}{\cdot 24\, R}\right)} = \cdot 25 \sqrt{\frac{S}{R}}$$

Expressing the exposed surface in square inches, we have $C = \cdot 64 \sqrt{\frac{S}{R}}$

Current density is expressed as so many amperes per square inch, and we will apply this last approximate rule to see what current density it gives. A wire to have one square inch of cross-sectional area must have a diameter of a little over 1⅛in., and the circumference will be [illegible] × 3·1416 = 3·543 in. Assume the wire is 200ft. long, therefore the cylindrical exposed surface will be 2,400 × 3·543 = 8,563 square inches, and the resistance in ohms at 50deg. C. above the atmosphere may be put down roughly at ·002. Inserting our values, we have

$$C = \cdot 64 \sqrt{\frac{8{,}563}{\cdot 002}} = 1{,}324 \text{ amperes.}$$

Hence, in order that the wire shall not heat up more than 50deg. C. or 90deg. F. above the temperature of the atmosphere, the current must not be more than about 1,[illegible] amperes for a conductor having one square inch area.

When the same amount of current flows through wires of different diameters, the temperature of the wire is inversely proportional to the fourth power of the diameter, because halving the diameter of a wire gives

times the resistance, and since the current remains constant, this means four times the heating effect; second, the mass is now only one-fourth of what it was previously, therefore we have four times the heat spent on one-fourth of the mass, so that its temperature will be sixteen times as much. Expressed in symbols, this law is $T \propto \frac{1}{D^4}$, where T equals temperature and D equals diameter.

(To be continued.)

SIGNALLING AND SPEAKING BY MEANS OF ELECTRICAL CURRENTS WITHOUT WIRES.

BY SYDNEY F. WALKER.

As a considerable amount of interest is being taken in the above at the present time, following on the article recently published in the *Times* dealing with Mr. Preece's and Mr. Gavey's experiments between the mainland and the Flat Holmes, an island in the Bristol Channel, it may perhaps be of service if the writer describes some experiments he has made in the same direction, and if he details the principles, as he understands them, on which work of this kind has to be conducted if it is to be successful.

The writer began to study this question some years since, and he has worked at it intermittently when time could be snatched from other work. He has succeeded not only in transmitting signals by the Morse code, using a magneto telephone as a receiver, but he has also succeeded in transmitting audible speech, spoken words, across a body of water without any other conductor except the intervening water, and under conditions that render it apparent that the transmission of speech across large bodies of water, within certain limits, is merely a matter of calculation.

The object the writer had in view in taking up the question was not the connection of lighthouses with the shore, but the transmission of signals, and of speech between ships at sea and between ships and the shore.

Eight years of the writer's young life having been spent as a midshipman and sub-lieutenant in her Majesty's service, he has been struck with the enormous advantage that would accrue to ships of all kinds if some reliable means of communication could be established between ships and the shore, or between individual ships at sea, that would be independent of the weather. He has a lively recollection of keeping a middle watch on the bridge of a man-of-war, creeping round the English and Irish coasts in a dense fog, or on a night so thick that one could hardly see two yards from the ship. If under such circumstances one could speak to the shore, and to any ship within a certain radius, the chances of collision and of shipwreck would be very considerably reduced.

The principles, however, upon which communication is established between ships and between ships and the shore are equally applicable to communication across large bodies of waters, such as the estuaries of our large rivers; and even, it appears to the writer, under favourable conditions, across large masses of the earth's crust, such, for instance, as from the surface of a mine to the working face.

In approaching the subject, which he has considered from all points, it has appeared to the writer that *conduction*, and not *induction*, should be the method employed in work of the kind under notice. One cannot, of course, have conduction without also creating inductive phenomena; but the writer's view is that conductive phenomena should be made use of, inductive phenomena being either guarded against or accepted, as they turn for or against the result sought for. It will be found, the writer believes, that inductive phenomena in the cases referred to assist the results obtained by conduction. The lines upon which the writer has worked are as follows:

If a conducting mass be taken—say, a cubical block of copper—and a source of electricity be connected, say, to two adjacent corners of the mass, the current which results will pass not only by way of the near face of the mass, but also through every other portion of the mass, passing in curves of smaller and smaller radius as the paths recede from the near face. Similarly, if the source of electricity be applied to two planes near the centre of the copper mass, the current would pass, not only across the mass by the shortest path, but also in curved paths on each side of this centre line.

Now, this being so, it follows that there will be a regular fall of electrical potential along each of the paths open to the current, and therefore that if connection be made at any two points in any one or more of these paths by a conductor which is connected with some apparatus that will denote the presence of a current of electricity, a current will pass through the apparatus and will work the apparatus—if the latter is sufficiently sensitive to respond to the current that will pass, in obedience to the E.M.F. present between the two points.

That is to say, supposing an E.M.F. of $\frac{1}{100}$ volt to be present between any two points in the conducting mass before referred to, and an apparatus, such as a telephone receiver, be connected to these two points, a click will be heard in the telephone, whenever either the local circuit in which the receiver is connected is made or broken, or when the circuit in which the generator is connected is made or broken, or its E.M.F. is varied sufficiently. Let the conducting mass be a body of water instead of a cable of copper, and let connection be made to the water by plates immersed in it, the plates being connected to a generator of electricity. It should follow, as the writer has proved it does follow, that if a second pair of connections be made with the body of water by means of a second pair of plates immersed in it, an E.M.F. will be present between these two plates which will cause a current of electricity to pass through any apparatus—such as a magneto-telephone receiver—that may be connected to them. And if this circuit can be made and broken, or the E.M.F. at its terminal plates sufficiently varied, the telephone will furnish audible evidence of the fact, and can therefore be used for the transmission of signals or of speech; provided that the initial E.M.F. present at the terminal plates to which it is connected equals that to which the instrument responds. But here, in the writer's opinion, we come upon the fundamental principle of the whole thing. A very powerful current may be delivered to a body of water by means of immersed plates, and yet it may not be possible to get the faintest sign of a current in a telephone connected to two other immersed plates. Putting the matter one step back, it is quite possible to apply a very powerful E.M.F. to such a conductor as a body of water, and yet to lose all trace of it at a comparatively short distance from the plates which are connected to the generator; while, on the other hand, according to the writer's experiments, it is perfectly possible to get signals and speech at some distance off. What, then, are the conditions of success? To answer this question, we have only to ask ourselves how we can lose an E.M.F. Only by using it up. And how can we use up an E.M.F.? Only by either the creation of an opposing E.M.F., or by allowing it to drive a current through a resistance, the product of the current and resistance being equal to the E.M.F. disposed of. If we force a current of 10 amperes through a resistance of 10 ohms, we use up an E.M.F. of 100 volts, and we shall find no trace of E.M.F. beyond the limit of the 10 ohms so long as the 10 amperes are passing.

We have a striking instance of this in the shunt-wound dynamo, another in the E.M.F. of a primary battery when furnishing a current. In order, then, that we may not use up our available E.M.F. before reaching the points from which we wish to take a current through our telephone receiver, we must arrange that the product of $C \times R$ up to those points does not equal the total E.M.F. originally at our disposal. And this is to be done by making both the E.M.F. and the internal resistance of the generator used very low, and, as far as we are able, the resistances of the paths leading to the plates connected with our receiver also low. A generator having an E.M.F. of 100 volts, and an internal resistance of ·1 ohm would, if wound for an E.M.F. of only one volt, probably have an internal resistance of only ·001 ohm.

Now, in dealing with this question, we have to remember that, no matter what arrangements we make for our connection with the water, whether we bury our plates in

ground on shore, or immerse them in the water; whether we make our plates large or small, the resistance of the paths open to the current, once it reaches the water, must be very low indeed, as these paths comprise the whole body of the water, and will stretch away from the first connections in all directions.

If, then, the initial E.M.F. of our generator is high, and its internal resistance is also comparatively high, the large current which must pass into the water, unless the E.M.F. has been reduced before it reaches the water, will absorb the whole of the available E.M.F. by reason of the charge made by the internal resistance for the passage of the current. Taking the figures given above, and supposing the aggregate resistance offered by all the paths between the two generator plates, those connected to the generator, be ·01 ohm, as may very easily be, the current passing out from the generator would be $\frac{100}{\cdot 01}$ amperes = 10,000, and this would absorb considerably more than the E.M.F. available. Even if the resistance of the water paths was as much as ·1 ohm, the current passing would be 1,000, which would bring the E.M.F. at the plates to nil. Of course, in the first case the current mentioned would not pass, because the E.M.F. would be used up long before it reached that figure. The result would be the same, though, so far as picking up a current at the telephone plates was concerned. With the other winding furnishing one volt and with an internal resistance of ·001 ohm, the current passing where the aggregate resistance between the generator plates was ·01 ohm would be 100 amperes, and as this would only involve a charge of 1 volt, there would be ·9 volt left between the generator plates to send a current on to the receiver plates.

The writer has measured the E.M.F. required at the terminals of one of the watch magneto telephone receivers now in common use, and he makes it $\frac{1}{1000}$ volt. So that, assuming the figures given above, the resistance of the circuit formed by the two generator plates and the two receiver plates, passing from one generator plate to one receiver plate, thence to the other receiver plate and thence back to the second generator plate, may be very considerable before signals are lost. And as the variation of E.M.F. required for transmitting speech is even less than that required for signalling by the Morse code, the resistance of this circuit may be even greater for speech than for signals. This means that the larger the generator and receiver plates are made, provided the resistance of the generator and its connections to the receiver are sufficiently low, the farther may signals or speech be transmitted.

It should be thoroughly understood in connection with this matter that once the current passing through the remainder of the water, or whatever other paths may be open, is provided for, this path from the generator plates to the receiver plates acts quite independently of all the other paths, and will transmit its current to the receiver, just as if it had been an insulated wire lying in the water. Electromagnetic induction will, of course, be present, but, as before remarked, this will aid the desired result.

It follows, as a natural consequence, that the farther the generator plates are apart, the farther may signals and speech be transmitted, and also the farther apart the receiver plates can be placed, the farther can speech and signals be transmitted.

For a given size and distance between the receiver plates, the distance at which signals and speech can be received will depend inversely upon the resistance of the generator, and directly upon the size of the generator plates and their distance apart. It follows, also as a natural consequence, that the better conductor the liquid is, the shorter the distance to which speech and signals can be transmitted, other conditions being alike. The distance is greater in fresh water than in salt water, and in absolutely pure water it is at its best.

It also follows, from the above, that the presence of a metal conductor, such as the body of an iron ship, tends to reduce the distance, but this is only as the limit of the particular generator is reached. With a generator of very low resistance the iron body of the ship does not affect the result till a long distance is reached. The writer's plan for communications with ships, either from other ships or the shore, is to place on board the ship a dynamo of low voltage and very low resistance, connecting it by conductors of low resistance with copper plates at the bow and stern, the plates being insulated from the body of the ship. On shore, as already indicated, would be another pair of plates, these being, in fact, arranged in pairs all round the coast, connected by conductors of low resistance to a generator similar to those used on board the ships. Signalling or speech is effected by means of a sending key, or a microphone transmitter and induction coil, arranged as a shunt to the generator plates, its resistance of course being such that it can only take the current it can make use of. By either of these methods the required variations in E.M.F. are communicated to the generator plates, and from them to the receiver plates. It follows, of course, that by this arrangement each pair of generator plates are also receiver plates and [illegible] the receiving telephone being connected to the [illegible] either as another derivation or in series with the secondary of the induction coil, as most convenient.

The question of calling attention has, of course, to be dealt with. In the writer's opinion this will not be difficult. On board ship and at look-out stations on shore men can be constantly listening at the telephone [illegible] greater inconvenience than the regular look-out man now suffers. The writer believes, too, that it would be practicable to arrange a relay worked by a subsidiary telephone to make the connection of a local circuit in which a bell and battery were included in the ordinary way, or [illegible] another derivation from the generator. The problem of using delicate telephonic apparatus on board ship is more serious, on account of the difficulty of keeping the connections in order. That difficulty, however, could be overcome, in the writer's opinion, by giving increased wearing [illegible] to the connecting portions of the apparatus, by teaching seamen the principles upon which the apparatus is [illegible] and by giving them plenty of spare parts to take [illegible] with them.

One other difficulty remains to be dealt with, so far as the writer has gone at present—viz., the effect of storm waves. He has tested this as far as can be done on a limited scale, and he finds, as might be expected, that the effect is to produce a continuous crackling in the telephone receiver, similar to that produced by telegraphic [illegible] in wires running on the same poles with unbalanced telephone wires. This would appear to indicate that speech [illegible] be more difficult in stormy weather, but not impossible.

OBITUARY.

THE LATE DR. WERNER SIEMENS.

We regret to record the death of Dr. Werner Siemens, which took place on Tuesday last. The name of Siemens is familiar to English ears; in fact, we are almost in the habit of looking upon the firm as an English firm. This may not be quite correct, but so intimately is the English branch welded into our industrial edifice, and so intimately is the name of Siemens connected with our steel manufacture, with electric lighting and power and cable enterprise, that we may claim it as indigenous to the soil. The late Dr. W. Siemens was the first representative of the firm here, worthily followed by Mr. A. Siemens. The late Dr. Werner Siemens was, we believe, principally resident in Berlin, and represented what might be termed the [illegible] actor of the firm. He was born in 1816 at Lenthe, near Hanover, and educated at the Lubeck Gymnasium. He entered the army, gaining the rank of lieutenant in 1837, but while engaged in military duties his studies were devoted to scientific subjects, and he took out a number of patents for various inventions. As a member of a commission of the Prussian General Staff for the introduction of the electric telegraph system in place of the optical telegraphs, he proposed in 1847, the application of subterranean conductors insulated by guttapercha, and executed successfully experimental lines coated with guttapercha by means of a press invented by him for that purpose, which is still used in the manu[illegible]

facture of cables. With the help of these insulated wires he succeeded in laying, together with Prof. Himly, the first submarine mines with electric ignition in the spring of 1848, for the protection of the harbour of Kiel from the Danish fleet. In the same year he carried out the first great telegraph line in Germany between Berlin and Frankfort-on-the-Main, and in the following year the subterranean line between Berlin and Cologne. Dr. Siemens left Government service in 1850, and devoted himself afterwards entirely to scientific studies and private enterprises. In 1847 he had already laid the foundation of the telegraph works, carried on afterwards by him under the firm of Siemens and Halske in Berlin. Six of the existing Atlantic cables, as well as many others, were laid by Messrs. Siemens Brothers, to the formation of which company Dr. Siemens greatly contributed. Dr. Siemens was the inventor of the pneumatic tube system and several important improvements in dynamos, and was an honorary member of the British Association and of most of the European electrical and scientific societies. In 1886 Dr. Siemens presented 500,000 marks to the German nation for the foundation of a national scientific and technical institution. In 1888 he was ennobled, and in the same year he published a collection of scientific treatises. The degree of Ph.D. was conferred on him by Berlin University in 1874.

INSTITUTION OF ELECTRICAL ENGINEERS, Dec. 8.

Prof. W. E. Ayrton, F.R.S., in the chair.

The annual general meeting was held at the Institution of Civil Engineers, when the minutes of the last meeting were duly received and confirmed.

Mr. Thomas Joseph Gough, 159, Church-lane, Gorton, Manchester, was balloted for and duly elected as an associate.

The **President** referred to the loss the Institution had sustained in the death of Dr. Werner Siemens, who was perhaps the most famous o the famed band of brothers. His wide study of science could be best seen by an examination of the memoirs so recently published, and of which one volume was translated into English. There was a leading thought through these memoirs to show how a boy, starting with no particular privileges, could reach into the highest ranks of science. He concluded by proposing a vote of condolence and sympathy to the widow and family of Dr. Werner Siemens.

Prof. Forbes seconded the vote, which was carried unanimously.

The **Secretary** then read the annual report of the Council, which stated that the number of members elected during the year was fewer than the number elected last year, for reasons well known, as the new regulations came into operation in January last, and many men were elected last year who would in the ordinary course have been elected this year. Still the number was above the average, being nine honorary members, 12 members, 101 associates, and 98 students. During the year the Society had lost 22 members by death. Of the papers read during the year the premiums had been awarded as follows:

Institution Premium, £10, to Mr. Nikola Tesla.
Paris Exhibition Premium, £5, to Mr. Reckenzaun.
Fahie Premium, £5, to Messrs. Heaviside and Jackson.
The Salomons Scholarship had been awarded to Mr. Woodhouse, of the Central Institution.

Reference was made to the Chicago Exhibition, and the apathy shown by English manufacturers to exhibit there. The Institution had sent out an appeal trying to get a representative collection of apparatus under one exhibit, but still the manufacturers held aloof, and made no response to the appeal; hence the effort to obtain such an exhibit had to be abandoned. The finances of the Institution were satisfactory. An index to the volumes of the *Proceedings* has been compiled, and will be ready in a week or two.

The **President** moved, and **Mr. Stroh** seconded, the adoption of the report, which was carried after a discussion as to the present method of electing associates, brought forward by **Mr. Trotter**, who thought the present method needed alteration. General Webber, Sir D. Salomons, and several members made remarks, but ultimately the question was left in the hands of the Council.

General Webber moved and **Mr. Mordey** seconded a resolution of cordial thanks to the Institution of Civil Engineers for the use of the hall in which the meetings of the Institution of Electrical Engineers was held. The President and Council of the Institution of Civil Engineers had shown great kindness and consideration for the welfare of the Institution in so granting the hall, not only for the scheduled meetings but for the many supplementary meetings the plethora of papers and lengthy discussions necessitated. The resolution was carried unanimously.

Sir David Salomons moved and **Prof. Hughes** seconded a vote of thanks to the local honorary secretaries, of whom three had been lost by death during the year—viz., those of Japan, Norway, and Germany. The resolution was carried unanimously.

Mr. Swinburne moved a vote of thanks to the honorary auditors, Messrs. Danvers and Stroh, to which **Mr. Stroh** returned thanks for his colleague and himself.

Mr. Crompton moved, and **Prof. Fleming** seconded, a vote of thanks to the honorary solicitors, which was carried unanimously.

The discussion on Dr. Fleming's paper was resumed by **Mr. Mordey**, who desired to speak at length only upon one point in the paper—the sudden rush of magnetising current into the transformer, mentioned towards the end of the paper. In the first place, however, he would refer to the question of loss in the iron, a subject with which his name had been freely connected, but he had really nothing fresh to say in the matter. His original investigations were brought before the Institution and corroborated in two series of experiments by Prof. Ayrton, but in a third series of experiments Prof. Ayrton had failed to find the effect, so that his corroboration might be said to be cancelled. The speaker stated his intention to resume the experiments as opportunity offered, and if he found his previous results wrong, would come before the Institution and make a clear breast of the matter. He was highly amused at anonymous people hiding themselves behind leaderettes, and speaking of his results as contrary to "Nature's laws." He did not understand "Nature's laws," but these people did, and infallibly knew all about the behaviour of iron under all circumstances. However, he quoted a sentence from a letter of Prof. Ewing, an investigator who had paid more attention to this subject than any man of them or all of them put together, in which Prof. Ewing thought that his (Mr. Mordey's) results were in accordance with molecular theory. The speaker then went on to say that since the reading of Prof. Fleming's interesting paper he had carried out several series of experiments on the question of the rush of current into the transformer. At first he thought that it was a capacity effect, but his experiments had proved conclusively that it was not so, and that the views of Dr. Fleming on this point were correct. A large number of contacts with different transformers at frequencies of 83 and 100 showed the effect was greater at lower frequencies. It was greater when the break was very quick, when the magnetic effect had not time to die away. With a slow break it did not happen. Contrary to Dr. Fleming's remarks he found it occurred both ways of transforming. He found it was not a current effect but a magnetic effect, and did not occur in both circuits. Exciting by secondary cells in the same direction a lamp became brilliant in 1 or 1½ seconds, in opposite direction four or five seconds. Elphinstone and Vincent had alluded to residual effect in 1880, showing a magnet with single cell supporting 1lb., when disconnected could be gradually loaded up to carry 50 ounces.

Mr. Crompton, after alluding to his experience, said transformer distribution had not reached the figure he had given years ago, though direct current had. Transformer engineers did not know yet the losses in primary, much more secondary wires. The ideal coal per unit was 3·7lb., best results by low tension 6·4lb., but by alternating it was still 16lb., two-thirds the loss going in transformers. With average private house load a Mordey transformer gave 49.5 per cent., and Westinghouse 54·5. Stations had a load factor of 10 to 14, and houses two to three; large substations might approach the former, but would be usually about 7 per cent. With the best results given by Dr. Fleming, the annual efficiency could not rise above 80 per cent., but if the paper elevated the efficiency from 50 to 80 per cent. it would have given great gain.

Dr. Sumpner said the wattmeter method of testing was the more practical of the two proposed. The explanation of the wattmeter effect had been really pointed out by Dr. Fleming six years—the lag of eddy currents in a suspended plate.

The discussion was adjourned to next January.

Mr. W. H. Preece was announced as President for the ensuing year, the list of officers being as given in our last.

ELECTRIC LIGHTING PROVISIONAL ORDERS, SESSION 1893.

GAZETTE NOTICES AND MAPS DEPOSITED AT THE BOARD OF TRADE ON OR BEFORE THE 30th NOVEMBER LAST.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. IX. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

Apprentice.—*Letters are awaiting you at our office.*

A PLAUSIBLE SCHEME.

By terming the scheme which Mr. Thwaite has proposed in his paper to the Manchester Association of Engineers a plausible scheme, we intend no disparagement, but rather desire to indicate that it is a very taking project. From the earliest development of electric lighting in the eighties the idea has periodically been expressed that *the* proper way to obtain electrical energy in our large towns was to generate it at the coalfields, and from thence conduct it to the points required. If our memory serves us correctly, Prof. Perry rather made a hobby of such a project, contending that the economy of the large engines that might be used, and the low price of fuel, would make such a scheme, when carried out in practice, a paying concern. Mr. Ferranti, too, was evidently of a similar opinion when he designed the Deptford station. Certainly he did not go to the coalfields, but his aim was large units, the most economical large engines, and a point where coal could be cheaply placed in the bunkers of the boiler-room. Mr. Thwaite argues in favour of gas engines of large power, and many men agree with him. Theoretically, we believe, most men agree with him, but, practically, they shirk putting entire faith in gas engines of large calibre because they have not been extensively tried. It is all very well to say that compound gas engines of 1,000 i.h.p. can now be had for the ordering, but before a buyer risks his money he wants to know where such engines are to be seen, how long they have been running, and the practical results of such running. We have no word to say against the possibilities of such engines, but the general public before they contribute to share capital will require satisfactory answers to such questions as those we have indicated. Assuming, however, that either gas engines of the size required are thoroughly reliable, or that steam engines would be used, the scheme presents no grave difficulties. Long-distance transmission has not the same terrors it formerly had. We are becoming more and more accustomed to consider larger and larger works, till 50 miles more or less are taken to mean simply so much more initial cost for mains and an annual loss of pressure which can soon be calculated. It is evident that the Lauffen transmission experiment gave the impetus to Mr. Thwaite, in that his estimates for plant are derived from foreign sources, from the men, in fact, who had experience during the Lauffen-Frankfort experiment. These estimates are really very moderate when the whole scheme is considered, as will be seen when the conclusion of the paper is given next week. We may, however, now say that three principal generating stations are proposed—one to supply Manchester and the Ship Canal, Blackburn, Bolton, Preston, Liverpool, Oldham, Chorley, Ashton, Stockport, Warrington, St. Helens, Runcorn, Widnes, Heywood, Burnley, Bury, Rochdale; the second to supply Leeds, Sheffield, Bradford, Halifax, Huddersfield, Wakefield, Dewsbury, Rotherham, Stalybridge; and the third to supply 1, Mansfield; 2, Nottingham; 3, Derby; 4, Melton Mowbray; 5, Leicester; 6, Market Harborough; 7, Kettering; 8, Northampton; 9, Bedford. 10

Hitchen; 11, Luton; 12, St. Albans; 13, Greater London; 20, Wolverhampton; 21, Birmingham; with a stand-by, or second station, in the last case in the Staffordshire district. The estimates for providing engines, dynamos, switchboards, transformers, and trunk mains are, respectively, £340,000 and £334,800 for a 10,000-h.p. transmission plant, the generating station being at the Yorkshire coalfields, some 120 miles away from the metropolis, while the estimated receipts are sufficient to warrant an expenditure of half a million. It is always a dangerous matter to estimate receipts and time of full load, as in these directions the author is apt to look very favourably upon figures. Further, the expenditure is only for a part of the necessary equipment of a company. Nevertheless, the scheme is one that commends itself for close examination, and no doubt there will be ere long an effort made, not perhaps to carry out this scheme in its entirety, but to establish a central station on a coalfield, and from thence to supply the towns within a radius of twenty or thirty miles.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

RE FIRE AT LONDON STEREOSCOPIC COMPANY, REGENT STREET.

SIR,—My attention has been called to a letter published in the last issue of one of your contemporaries signed by "J. D. F. Andrews."

The statement he makes therein—that I examined and passed the electrical installation at the London Stereoscopic Company's premises—contains not a single word of truth. I knew nothing whatever about the installation, nor were any of the insurances effected in the Phœnix Fire Office.

With regard to Scott's Oyster Rooms, I never saw the installation, nor was I even aware that the electric light was in the premises. Neither was the Phœnix Fire Office aware that there was any electrical installation, the work having been placed up some years ago, when the premises were insured in another fire office. As to whether there is the slightest justification in laying the charge of the fire to electricity, I leave those concerned to say if they think it worth their while.

I must request you to publish this letter, as the false and misleading manner in which Mr. J. D. F. Andrews has made use of my name makes me depart from my rule of passing unheeded erroneous or unjust statements in print with regard to myself or work.—Yours, etc.,

December 6, 1892. MUSGRAVE HEAPHY.

PRICE OF ELECTRIC SUPPLY.

SIR,—In reference to Dr. Hopkinson's proposed method of charging for electricity in Manchester, I believe I may claim to have been the first to suggest a scale of charges depending on the maximum current demanded by a consumer.

The schedule of prices for the electric lighting license granted to the Liverpool Electric Supply Company in 1888 contained a sliding scale of charges per quarter, which may be shortly expressed as follows:

1. For any number of units up to 100 times the number of units per hour of maximum demanded supply, 1s. per unit.
2. For any further quantity up to 100 times the maximum demanded supply per hour, 8d. per unit.
3. For any further quantity, 4d. per unit.

For example, a consumer demanding a maximum supply of three units per hour, and having used 1,100 units in a quarter, would be charged the following rates: 300 units at 1s., 300 units at 8d., and the balance of 500 units at 4d.

It was found, however, that the consumers had some difficulty in understanding the scale, being accustomed to the sweet simplicity of the uniform rate charged by the local gas company, and that dissatisfaction was always expressed by consumers who used their lamps only a small number of hours, and therefore never reached the lower rates.

All sliding charges based on the maximum demanded supply have the serious disadvantage of limiting the number of lamps fitted up by a consumer to the smallest number he can possibly do with, thus preventing the adoption of the light in positions where the lamps are only occasionally required.

A sliding scale is also an obstacle to the introduction of the light in buildings not often used, and especially churches, which are valuable customers to a supply company on account of only requiring a supply on Sundays, when the central station load is at a minimum.

Four years' trial of the above method of charging in Liverpool proved that its disadvantages were greater than its advantages, and, consequently, in the Liverpool Electric Lighting Order of 1892, the sliding scale was repealed and a uniform rate of charges substituted.

The present price charged in Liverpool is 7½d. per unit, or about double the price of gas, and with a rapidly-increasing demand for electric light and the more efficient and cheaper incandescent lamps that may be expected when the present oppressive monopoly in lamps comes to an end next year, the day is not far distant when the electric light will, in addition to its many advantages, be, light for light, as cheap as gas.

A uniform rate has been found to answer well in the case of the greater number of gas and water companies, and is equally suitable for electric supply companies when the circumstances permit of a reasonably low price being charged.—Yours, etc., A. BROMLEY HOLMES.

Liverpool, December 5th, 1892.

VARLEY TESTIMONIAL.

SIR,—We shall be glad if you will allow us the opportunity of calling the attention of your readers who are interested in the above to the fact that although we have received encouraging responses and subscriptions from some of those we expected to aid us, yet the response as a whole has up to the present been disappointing, more especially on the side of the manufacturing community. We are sure that it will be found in most cases that this is due to our circular letter of appeal having been overlooked, owing to its being sent out during the season when a good many members of the electrical profession were away on their holidays.

The object of this letter is to remind them and all others who have benefited by the undoubted impulse which Varley's inventions gave to electrical engineering to send in, without further delay, their subscriptions, according to their means, to Mr. A. Stroh, 98, Haverstock-hill, N.W., endorsing subscriptions to Varley testimonial fund.—Yours, etc.,

A. STROH, Hon. Treasurer.
R. E. CROMPTON, Hon. Secretary.

SUPPLEMENTARY REPORT OF THE ELECTRICAL STANDARDS COMMITTEE.

To the Right Hon. A. J. Mundella, M.P., President of the Board of Trade.

Subsequently to the presentation of our former report to Sir Michael Hicks-Beach in July, 1891, we were informed that it was probable that the German Government would shortly take steps to establish legal standards for use in connection with electrical supply, and that, with a view to secure complete agreement between the proposed standards in Germany and England, the director of the Physico-Technical Imperial Institute at Berlin, Prof. von Helmholtz, with certain of his assistants, proposed to visit England for the purpose of making exact comparisons

between the units in use in the two countries, and of attending the meeting of the British Association which was to take place in August in Edinburgh.

Having regard to the importance of this communication, it appeared desirable that the Board of Trade should postpone the action recommended in our previous report until after Prof. Helmholtz's visit.

That visit took place early in August, and there was a very full discussion of the whole subject at the meeting of the British Association in Edinburgh, at which several of our number were present. The meeting was also attended by Dr. Guillaume, of the Bureau International des Poids et Mesures, and Prof. Carhart, of the University of Michigan, U.S.A., who were well qualified by their scientific attainments to represent the opinion of their respective countries.

It appeared from the discussion that a few comparatively slight modifications of the resolution included in our previous report would tend to secure international agreement.

An extract from the report of the Electrical Standards Committee of the British Association embodying the results of this discussion was communicated to us by the secretary, and will be found in the appendix to this report.

Having carefully reconsidered the whole question in view of this communication, and having received the report of the sub-committee mentioned in resolution 14 of our previous report, we now desire, for the resolutions contained in that report, to substitute the following:

RESOLUTIONS.

1. That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by her Majesty in Council as Board of Trade standards.

2. That the magnitudes of these standards should be determined on the electromagnetic system of measurement with reference to the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade.

3. That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second.

4. That the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in a mass of a constant cross-sectional area, and of a length of 106·3 centimetres may be adopted as one ohm.

5. That a material standard, constructed in solid metal, should be adopted as the standard ohm, and should from time to time be verified by comparison with a column of mercury of known dimensions.

6. That for the purpose of replacing the standard, if lost, destroyed, or damaged, and for ordinary use, a limited number of copies should be constructed, which should be periodically compared with the standard ohm.

7. That resistances constructed in solid metal should be adopted as Board of Trade standards for multiples and sub-multiples of the ohm.

8. That the value of the standard of resistance constructed by a committee of the British Association for the Advancement of Science in the years 1863 and 1864, and known as the British Association unit, may be taken as ·9866 of the ohm.

9. That the standard of electrical current should be denominated the ampere, and should have the value one-tenth (0·1) in terms of the centimetre, gramme, and second.

10. That an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of 0·001118 of a gramme per second may be taken as a current of one ampere.

11. That an alternating current of one ampere shall mean a current such that the square root of the time-average of the square of its strength at each instant in amperes is unity.

12. That instruments constructed on the principle of the balance, in which by the proper disposition of the conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by known weights, should be adopted as the Board of Trade standards for the measurement of current whether unvarying or alternating.

13. That the standard of electrical pressure should be denominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere.

14. That the electrical pressure at a temperature of 15deg. centigrade between the poles or electrodes of the voltaic cell known as Clark's cell, prepared in accordance with the specification attached to this report, may be taken as not differing from a pressure of 1·434 volts, by more than one part in one thousand.

15. That an alternating pressure of one volt shall mean a pressure such that the square root of the time average of the square of its value at each instant in volts is unity.

16. That instruments constructed on the principle of Lord Kelvin's quadrant electrometer used idiostatically, and, for high pressures, instruments on the principle of the balance, electrostatic forces being balanced against a known weight, should be adopted as Board of Trade standards for the measurement of pressure, whether unvarying or alternating.

(Signed) COURTENAY BOYLE. RAYLEIGH.
KELVIN. G. CAREY FOSTER.
P. CARDEW. R. T. GLAZEBROOK.
W. H. PREECE. J. HOPKINSON.
W. E. AYRTON.

(Signed) T. W. P. BLOMEFIELD, Secretary.

29th November, 1892.

SPECIFICATION REFERRED TO IN RESOLUTION 10.

In the following specification the term silver voltameter means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time average of the current, or if the current has been kept constant, the current itself, can be deduced.

In employing the silver voltameter to measure currents of about one ampere the following arrangements should be adopted. The cathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10 cm. in diameter, and from 4 cm. to 5 cm. in depth.

The anode should be a plate of pure silver some 30 square cm. in area and two or three millimetres in thickness.

This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the cathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing wax.

The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water.

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

METHOD OF MAKING A MEASUREMENT.

The platinum bowl is washed with nitric acid and distilled water, dried by heat, and then left to cool in a desiccator. When thoroughly dry it is weighed carefully.

It is nearly filled with the solution, and connected to the rest of the circuit by being placed on a clean copper support to which a binding screw is attached. This copper support must be insulated.

The anode is then immersed in the solution so as to be well covered by it and supported in that position; the connections to the rest of the circuit are made.

Contact is made at the key, noting the time of contact. The current is allowed to pass for not less than half an hour, and the time at which contact is broken is observed. Care must be taken that the clock used is keeping correct time during this interval.

The solution is now removed from the bowl and the deposit is washed with distilled water and left to soak for at least six hours. It is then rinsed successively with distilled water and absolute alcohol and dried in a hot-air bath at a temperature of about 160deg. C. After cooling in a desiccator it is weighed again. The gain in weight gives the silver deposited.

To find the current in amperes, this weight, expressed in grammes, must be divided by the number of seconds during which the current has been passed, and by ·001118.

The result will be the time average of the current, if during the interval the current has varied.

In determining by this method the constant of an instrument the current should be kept as nearly constant as possible, and the readings of the instrument taken at frequent observed intervals of time. These observations give a curve from which the reading corresponding to the mean current—time-average of the current—can

ECONOMIC POSSIBILITIES OF THE GENERATION OF E.M.F. IN THE COALFIELDS, AND ITS APPLICATION TO INDUSTRIAL CENTRES.*

BY B. H. THWAITE, C.E.

The recent history of the useful development of the application of electric energy reads like some marvellous story emanating from the brain of an Oriental dreamer. An engineer loving his noble art has only to look into this history with thoughtful interest, to be drawn into the train of constantly increasing length of those who follow and proudly own allegiance to this fair goddess Electra. After all, the employment of electric energy for the uses of man is only another instance of the wisdom of imitating the economic ways of Nature. The entire organic system, whether plant or animal, is controlled and reared by this magic and mysterious force that, like the initiation of life, can neither be understood nor described. The sensible impressions of life and the movement of the muscles are merely the result of this electric energy, produced by the chemical actions set up by the introduction of nitrogenous and carbonaceous food elements into a solution of the gastric juice of the human system. The spinal column is the transformer, the brain is the switchboard, and the nerves the conductors to the distributed motor elements of the anatomical system. The modern development of applied electrical science is extending these vital methods of dynamic effort to the external areas around man, by which, in the instance of, in one example, the nervous impulses moving his tongue are transmitted miles away to be imparted by the telephonic apparatus to the tympanum or drum of the ear of another and listening man. The brain impulses, or thoughts enclosed in speech, are thus transmitted beyond oneself in Nature's ways, so that here we have the natural electric impulses lengthened by the skill of man to an almost indefinite extent, and adding to the convenience and resources of humanity in its fight for existence. The force created by the energy of man is also transmitted to far off distances, and now we have our country becoming gradually converted into a semblance of the human nervous system, a semblance that, as time flies on, will become greater and greater. What could be more appropriate than the location of the electric energy producing elements in positions appropriate for the acquirement of the highest efficiency and economy, and in its transmission to civilised industrial centres where the impulses of nervous energy direct and control the operations of supply and demand of the requirements for sustaining life and the comforts associated with it.

The onward rush of this marvellous electric energy has drawn by its power of attraction most of the workers in the field of applied science but the field of operation is so expansive, and so allied to the engineering art that no engineer should draw back from the attractive embrace of this mysterious force. Unlike the evolution of the use of steam, and the conception of the steam engine, which was practically developed by the genius of one inventive mind—that of James Watt—the minds of most of the intelligent physicists and mechanicians of all civilised nations on each side of the Atlantic have been concentrated in the work of advancing the application and widening the field of use of this fascinating form of energy. Manchester, the cradle of many of the great engineering developments, has, through Joule and Wilde, contributed her quota to this laudable effort, and to-day it may be truthfully asserted that no other practical or applied science has had, measured in terms of time, an equivalent success to that of the application of the science of electricity and its uses, and the resulting sum of the intelligence of the workmen in this field of science is the greatest proof we have of the broadly advancing intellect of humanity. No other applied science has, by time measurement, received the same degree of mathematical treatment. Whether the progress of practical development has been benefited by this associated analytic treatment (and its deducing value possible by this mathematical analysis) may be an open question. Mathematicians are generally more of analysts than synthesists. They rarely conceive or create, although in Lord Kelvin we have a brilliant exception, but this may only prove the rule. It has been asserted that no real progress was made in the development of electro generating machines until the law of progress indicated by purely mathematical reasoning had been ignored. Be this as it may, it can be proudly stated that the present elements constituting the electric generator—*i.e.*, the apparatus for raising and lowering the pressure of the electric energy to be distributed, its distribution and final employment at pressures of controllable limit in an averted or reversible type of electric machine, have been raised to an almost maximum possible degree of efficiency, at least eight times higher than the best of the high-class steam engines now constructed. Divested of mathematical treatment the active and essential principles underlying and controlling technical electro dynamics can be mastered by any ordinarily intelligent engineer to whose craft in a great measure will fall the future care and control of this mysterious electric force.

These remarks are prompted by a desire to direct the eyes of all engineers to the importance of studying and mastering the main principles underlying the construction and application of electric generators and the intra elements between it and the motor. They will find a fascinating field open before them, in which everyone may discover a furrow in which to plough for his own advantage and for the benefit of an expanding electro-technical science. Switzerland, thanks to her natural waterfall resources of the Alpine areas, is rapidly becoming an industrial centre of an importance, diversity, and magnitude far away beyond the dreams of the most ardent Swiss patriots. And this cheap and convenient power is inviting, with effect, the opening up by not only the Swiss republican citizens, but by strangers, of new and important industries, and to-day Switzerland may be said to annually produce the largest weight of aluminium of any country in the world. Our own carbonaceous fuel power resources have been one, if not the main, source of England's industrial greatness, but with the entrance of this new electric agent into the domain of practical engineering, the advantage we owe to our contiguity to the coal fields and to our possession of these fuel supply areas is being gradually undermined, and unless we utilise these resources so as to obtain the maximum practicable recovery efficiency from them by the aid and assistance of this wonderful electric agent, our industrial career will have another and serious retrogression.

Our coalfields have advantages that neither falling torrents of water, high tidal ranges, nor yet the force of wind currents possess. The supply of energy is constant, and does not depend upon the temperature of the one nor the barometric pressure and lunar dependence of the other.

Advantages of a Central Power Generating Station, or the Distribution of the Power from a Central Source.

The arguments that may be pertinently advanced in favour of a central power generating station are almost identical with those associated with the centralisation of a gas and water supply or a sewage treatment station, but the arguments are more adequate than those in favour of either of these examples. Assuming for a moment that the textile and other factories and workshops were all connected up with the power transmission mains carrying power generated at some large centralised power generating station. The factory owner would not then have the anxious responsibility of his power plant, involving the care of the [illegible] and unskilled labour element. The space absorbed by the steam boilers and economisers, engine house, coal stores, and chimney would not be required, and in towns this consideration might not be of unimportance. Then the troubles of coal and suitable water supply, and all the attendant requirements involved in the proper care and supervision of a steam engine plant would be avoided. The boiler insurance question would not trouble him. He would, in respect to his motive power supply, be as free from care as the proverbial jolly miller, whose power came from the winds of heaven or from the falls of rivulet and stream. The waste of fuel in early lighting and during meal hours would be avoided, and the excess of labour always associated with the conditions of isolated and comparatively small steam power plants would be saved. At the exact hour in the morning the mere movement of a switch throws the plant into operation, and at night the quick turn of a switch handle cuts off the power. The interest on the cost of the transmitting gear, the steam engine, the steam boilers, and the buildings during 14 hours out of the 24, which is at present lost would, by the supply of power from a central generating station, be avoided. The same main service, with the addition to the electromotor of a transformer, would be available for lighting purposes, for elevating goods and traversing them, and for ventilating, fire extinguishing, electrolytic, and innumerable other purposes. In the event of a decision to stop the factory for an indefinite period, there is no expensive staff to maintain the plant in a condition of efficiency. In deciding to stop the works or to disestablish them, the serious question always facing the owner of a steam engine and boiler plant—"of what shall I do with it?"—is met by the simple request to the staff at the central generating station to remove the electromotive power plant. This can be done without any trouble, and with little depreciation in the value of the machines. Whereas, who would lightly face the removal of a large steam engine, steam boiler, and economiser plant? not to mention the abandonment of the chimney and buildings. We all know the number of steam engine and boiler plants lying and rusting away at various abandoned or unlet works throughout the country, each plant having in its time the possibilities of useful work. The reduction of skilled labour required in proportion to the power produced that would follow the establishment of a coalfield [illegible] generating station, would be very great; in fact, this feature [illegible] justifies the correctness of the principle, on economic grounds, of the establishment of large central power generating stations. Another feature is the fact that an additional extension, [illegible] extra power plant, can easily be accomplished, whereas we all know how difficult in many instances it is to add [illegible] steam power plant simply owing to the exigencies of space and position. The compactness of the electric generator [illegible] permits it to be placed in positions absolutely [illegible] any other kind of power generating plant. Besides these advantages, there would be no [illegible] factory chimney [illegible] forth its smoke to poison the atmosphere and [illegible] the [illegible] natural laws involved in the [illegible] of energy.

Thanks to the commission appointed some years back by the Birmingham Corporation to report upon the [illegible] we are able to look through the matter of [illegible] of the existing system of power production and [illegible] few sentences their more important disadvantages. The [illegible] the only rule of that [illegible] their duty [illegible] testing a great number of engines in everyday work and varying in power from [illegible] The total [illegible] tion was ascertained, as well as incidental or [illegible] Owing to the extremely intermittent and varying [illegible] duty, the engines working under the most favourable [illegible] only averaged throughout the day one-third of their working capacity, but under the worst conditions only [illegible] the maximum capacity was utilised. The coal consumption in the most favoured examples was [illegible] lb. per indicated horse-power

* Paper read before the Manchester Association of Engineers.

per hour upon the average daily horse-power, and in the worst example the coal consumption attained the phenomenal one of 36lb. per indicated horse-power per hour. The commission carefully state that these results are not due to the imperfect construction of the engines, but are consequent on the varying character of the work required, and the necessity imposed upon each power user of maintaining a plant and steam engine equal to his maximum requirements. His motive power must be at hand and be available often at a moment's demand, and in the interim steam is blowing from and fuel is wasting at his boiler. The following advantages were accepted as belonging to any economic and effective method of distributing power to small users, and available for direct application to isolated machines: No heavy and costly foundation; no expensive shafting required; no smoke nuisance; no ashes or removal by cartage; cost of water and coal avoided; no danger from explosion; full power at any moment; only to pay for power in proportion to amount used. A municipal advantage would be the lessened coal traffic through the streets, and waste of the fuel *en route*.

As an illustration of the advantage of central supply plants in lieu of isolated ones, and which will be still further emphasised, practical standard of efficiency and satisfy the exigencies of duty is as follows:

1. The conversion of the solid fuel into a gaseous condition.

2. The abstraction of the nitrogenous value from the fuel, and its conversion into a condition suitable for agricultural fertilisation.

3. The direct combustion of such gaseous fuel in the combustion cylinder of a gas motor, for the conversion of the thermic into dynamic energy.

4. The transformation or transmutation of this dynamic into electric energy, or into E.M.F.

A diagram was shown which gave with approximate accuracy the apportionment of the thermic capital supplied by a gas or a steam engine and its allocation for useful, effective work, and the loss by unavoidable dispersion by conduction, sensible heat, and as unexpended thermo-chemical assets in the waste gases. The ultimate possible results of a fuel gas and gas motor plant on a large scale, is, that with such a plant, the dynamic power enclosed in the indicated card of pressure of a cylinder will be equivalent to the raising or elevation of 33·000lb. 1ft. high in one minute may be obtained with an expenditure of from ¾lb. to 1lb. of solid

ELECTRIC POWER TRANSMISSION FROM COAL FIELDS.

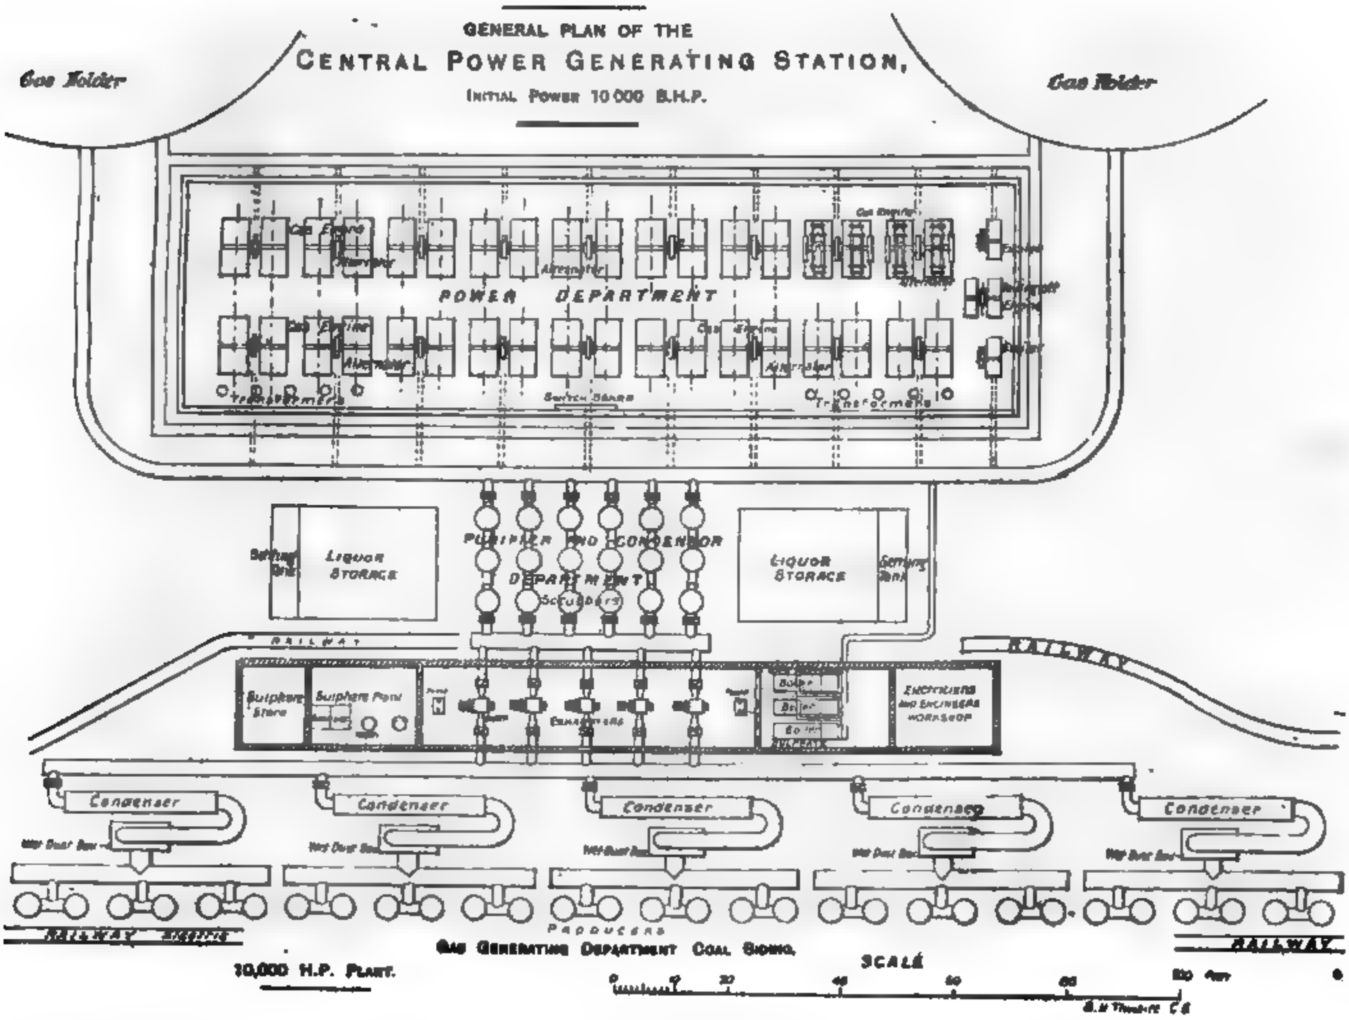

FIG. 1.

let us refer to one example. If there are 10 engines, each of 10 h.p., and each engine is required to work only one hour during a day of 10 hours, under the present system at least 100 h.p. of steam-producing plant would be necessary, whereas with a central power generating station connected with each works it is quite possible, where the working hours are sufficiently distinct to adequately permit of an engine power equal to 20 h.p., to supply the wants of the 10 power consumers. The first consideration is to convert the thermic value potential into dynamic energy, and with as high a degree of efficiency as possible. We know in precise terms the degree of thermic energy possessed by the fuel; we know also that, besides this thermic capital, the fuel contains a nitrogenous constituent which it is our bounden duty to restore to the plant life from which it originally emanated, and this same duty should compel us to return the carbon of the fuel to the plant in an assimilable form as carbon dioxide and the hydrogen as H_2O, or water. Is it possible to define what is the most economic and practically ideal method of converting heat into work with the assemblage of mechanical parts at present available from actual working data? An answer in the affirmative may be given. The inevitable conclusion of everyone who examines the subject without bias will be that the procedure that will give this ideal method to fulfil the highest fuel That the fertilising value from this fuel should be equivalent to the supply per ton of fuel of the equivalent of the nitrogen to that contained in 22lb. to 28lb. or more of ammonia sulphate. At present these conditions cannot be economically obtained from any other form of motor-generating procedure or plant than a gas engine. The procedure of the steam-engine method has an associated loss far greater than the gas engine, and although it is possible to convert the fuel into a gaseous condition and recover the nitrogen, there are losses attending the employment of such a procedure that partly neutralise the gain. It must be obvious to anyone that direct and perfect combustion actually inside the walls of a motor cylinder must be more economic than the combustion more or less imperfect in the flues of a steam boiler, even if effected under the most favourable conditions. Besides the fundamental advantages of the gas plant and gas motor procedure, the instrument itself is more effective in its useful disposal of work represented by the indicated energy. Take the indicated energy of both the gas and the steam motor and compare it with that available for external work; it will be found that the former is very much more efficient. It is well known that with the type of steam engine utilised on our ocean liners and for driving our largest mills, the reduction in expenditure of fuel for a given dynamic output and value is very consider-

able, and the reduction is a striking and eloquent witness in favour of large power steam engines, which are only available for centralised power stations. But for generating power for driving electric generating machines we require still higher efficiencies, and with relatively smaller powers. A motor of 300 h.p. is the largest that should be used for this character of work. The efficiencies of dynamos or electric generating machines are so nearly perfect that there is only questionable advantage in building excessively large types; but the motive power and elements should be such that, if one or two parts go wrong, it will not involve the arrestation of the entire motive power plant. Besides, it should be possible to reduce or increase the power of dynamic energy production in proportion to the demand, and with large steam engines of 1,000 h.p. and upwards this would not be practicable. There is another and important advantage in relatively smaller power gas engines: the pulsations of piston effort could be so arranged that their effect on the supply would be inappreciable. In the arrangement of the plant, Fig. 1, for the projected coalfield generating stations, gas motors of 300 b.h.p. are intended to be used, a pair of these engines being allotted to each alternating current machine, coupled direct, one engine driving the armature in one direction, and the other the field magnets in a contrary direction.

Chronologic Table showing the Genesis and Historic Phases in the Development of Electric Transmission of Dynamic Energy.

Date.

1826. Conception of the idea that when an armature was forcibly removed from a permanent magnet, the force expended in this removal set up a current in wire surrounding the armature. Discoverer, MICHAEL FARADAY.

1865. The direction of the current produced by the severance of an armature from its poles to a wire surrounding the poles, the result being an increased inductive action and increased induced current, the intensity accumulating until the saturation point of the bar of iron forming the magnets is reached. Discoverers, VARLEY and WERNER SIEMENS.

1867. The use of electromagnets excited by the current from a separate electric generator machine in lieu of the steel magnet. Discoverer, WILDE (Manchester).

1873. Accidental discovery of the reversibility of the electric generating machine at the Vienna Exhibition.

NOTE.—It appears the Gramme Company had two dynamos on view and intended for lighting purposes. One of these machines was in motion, the other idle; a workman seeing some electric cables trailing on the ground, and thinking they belonged to the second machine, connected the cables up to the terminals of the machine that was idle. To his surprise the armature of this machine commenced to revolve. Discovery accidental.

1891. The triphasic alternating current system (high pressure) applied by the Maschinen Fabriken Oerlikon for conveying power over 100 h.p. from Lauffen to Frankfort, a distance of some 112 miles, with a loss varying from 30 per cent. This is the most triumphant success hitherto recorded in the transmission of power over long distances. Fuller details are given in the table of power transmission, *vide* appendix.

N.B.—The triphasic alternating system, known as the Drehstrom, consists in the use of three wires, each having its corresponding alternating current; the phases of impulses follow each other.

Our Natural Sources of Power.

In the face of new industrial competitors, who owe their competing origin to the energy of falling water and its electric possibilities of transmission, it is worth while to enquire whether or not we have natural power resources as auxiliaries to our coalfields. The author had reason a short time back to make a careful examination of the hydrographic data available, and from this he has prepared the diagram which shows at a glance the minimum tidal flow of the British ports having a range of possible use. The author entered very carefully into the question of whether it was economically possible to provide Weston-super-Mare, having a high tidal range, with power by means of turbines placed in the impounding walls enclosing water at high tide, the high tide water flowing through turbined shafts to the low tide level; but on examination of the probable cost of retaining walls, turbines, and turbine shafts, he found that it would be less costly to erect a central power generating station on the opposite Welsh coast, and convey the energy by submarine cable laid across the Bristol Channel. The wind power in inaccessible positions removed from fuel areas of supply may, by the employment of modern wind sail mills, be suitable for generating E.M.F.

Methods of Transmitting Power.

The practicable methods of transmitting power may be divided into three: firstly, the hydraulic; secondly, the pneumatic; and thirdly, the electric. For ordinary quick speed work hydraulic transmission of power is not very suitable. Air or pneumatic power transmission is economically applicable for short distance transmission of small power. In the pneumatic system for forwarding light parcels, as adopted at the General Post Office, London, and at Liverpool, pneumatic transmission has its happiest application; but for comparatively heavy work, and distances over two miles, the loss of efficiency is most serious. On the day of the discussion of Mr. Sturgeon's paper, read at Liverpool in 1887, and describing the Birmingham compressed air distributing scheme, the author received a letter from Mr. Charles Brown, stating that the Oerlikon Company had succeeded in transmitting several horse power of energy over a distance of some eight miles with a loss of only 25 per cent. It must have occurred to those who understood the meaning of this information that such an economic result spelt obsolete all [illegible] other rival methods of transmitting power, and [illegible] that of the pneumatic transmission; and further, that such a practical result meant the opening out of a vista to the [illegible] engineers, the growing width and length of which it would be impossible to calculate.

Since this first practicable triumph the Oerlikon Company have laid down a very great number of power transmission installations, but none more famous than that of the Lauffen-Frankfort project, which suddenly and vastly widened the [illegible] of usefulness and effect of this magnificent triumph of man in the control of hidden mysteries of Nature's ways of work for the benefit of humanity. The Lauffen-Frankfort results demonstrated, beyond cavil or contradiction, that for distances of upwards of 100 miles the transmission of power can be accomplished with very little loss of the original potential energy, whilst its rival, the air compression method, has [illegible] practical exigencies, both in the instance of Birmingham and Paris. Whereas the electric transmission of power is a [illegible] in practical every-day rough and ready use in very many instances and in almost every part of the world, and is [illegible] up new centres of industry, and new processes of [illegible] and manufacture, that could not have existed without the transcendent advantages associated with the use of this [illegible] pulsating energy; and no record of man's genius [illegible] on which are set forth the history of the mastery of this [illegible] means of transmitting energy for the purposes of [illegible] embellishing life. The high tension, or pressure, system of transmitting energy has long been the acknowledged exp[illegible] the high efficiency of Faraday's condensation or [illegible] long distance planetary telescopy, and there is little [illegible] when we obtain the right insulation, the voltage, or pressure, of the pressure in electric transmission will be increased to such an extent as to enable a very light wire to carry enormous potentials of energy with very little and even negligible losses [illegible] due to ohmic resistance.

Cost of Energy to the Consumer.

Taking the report of the Birmingham Compressed Air Commission as a basis of computation it appears that the [illegible] of motive power plants did not exceed 20 h.p., and for all [illegible] below this the cost may be taken to vary in the [illegible] between £10 and £18 per annum per horse power. This [illegible] covers the cost and depreciation of the engine and boiler [illegible] repairs and lubrication, rent of land and buildings, [illegible] coal, water, and labour. The cost of this energy delivered [illegible] and including the hiring rates for motor [illegible] should not exceed £4. 10s. to £5 for 3,000 working hours per annum; it is most probable that the figures will be less [illegible] the charge for energy was made to cost the consumer from £7 to £9 per horse power per annum it would be a great gain to him, not to mention the lessened anxiety, and he could also arrange to pay for his power in proportion to the amount used. According to a letter from M. Emil Huber, of the Maschinen Fabriken Oerlikon, the price charged for energy varies from £7. 2s. for powers [illegible] 10 h.p. and not exceeding 200 h.p., but for very small powers [illegible] 10 h.p. as much as £16 per horse power per annum is charged to the consumer.

(To be continued.)

ELECTRIC TRACTION.*

BY FRANCIS G. BAILY, B.A., A.M.I.E.E.

The use of electrical energy as a means of locomotion is of recent development, though the idea and the first app[illegible] date back to the early days of electrical science, the first attempt [illegible] a carriage being in 1839. At that time primary batteries were the only available source of a large supply of electric current, and [illegible] transforming engines were very crude and inefficient, rendering all serious improvements in electric carriages impossible. [illegible] account it was not until 1873, when the reversibility [illegible] dynamo was proved, that the possibility of success in [illegible] traction was realised, and in 1879 a small experimental [illegible] was tried in Germany, with such good results that two years [illegible] a line was laid in Berlin for permanent use, and [illegible] running up to the present day. The first idea of [illegible] was to collect the current from an insulated conductor [illegible] side of the track, the current being generated at some [illegible] the line, but shortly after this time the invention of storage batteries suggested the simpler method of carrying the [illegible] energy about on the vehicle, thus avoiding the necessity [illegible] conductor all along the road, with its obvious [illegible]. The plan was found practicable, and for the last 10 years [illegible] has been a vigorous discussion, which has not yet been decided as to which method is the better.

The difference is a fundamental one. By the use of storage batteries the carriage is independent of any special track [illegible] is complete in itself, so long as the charge is not exhausted. [illegible] battery is replenished during idle hours, or is replaced [illegible]

* Abstract of lecture delivered to the Liverpool Polytechnic Society.

Swindon.—The tenders for one year's lighting of New Swindon by electricity or other means are to be sent in by 12th inst.

Lancashire Asylums.—The Lancashire Asylums Board have granted a sum not exceeding £1,150 for the lighting of Whittingham Asylum with electric light.

Accrington and Church.—The inhabitants of Church, near Accrington, have opened up negotiations with the Co-operative Society to light Church by electricity.

Removal.—Messrs. Gwynne and Co., engineers, have removed from Essex-street, Strand, where they have been established since 1852, to Brook-street Works, Holborn.

Eastern Extension Telegraph Company.—The receipts for November amounted to £49,851, as against £40,686 in the corresponding period, showing an increase of £165.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £3,185.

Paris.—We learn that the Popp Company has just signed a contract with the Compagnie de l'Industrie Electrique for the carrying on and improvement of their electric supply sector.

Penarth.—A discussion before the Local Board on the lighting of Penarth by electricity has been deferred. The sub-committee reported that they had communicated with the towns already lighted.

Bristol Condensers.—We understand that the contract for condensers for the Bristol central station, which was awarded to Woodhouse and Rawson United, Limited, has been thrown up by this company.

La Plata.—The trial of electric tramcars at La Plata was a great success. There was not even a semblance of a hitch. Several railway and tramway managers have been invited to another trial trip.

Bradford Great Northern Hotel.—The lighting of this magnificent hotel, which we described in our issue of November 11th, was carried out by Messrs. Woodhouse and Rawson from their Bradford branch.

Epstein Accumulators.—The Epstein accumulators have been installed for lighting purposes at Messrs. Davis and Timmins and at Messrs. J. H. Ladd and Co., the latter in connection with the Scott-Sisling system.

Commercial Cable.—A quarterly dividend of 1¾ per cent. is announced by the Commercial Cable Company, payable on the 2nd proximo. It has also been decided to redeem £120,000 of the outstanding debenture bonds on the 15th proximo.

Austrian Telephones.—The Austrian Government is understood to be contemplating the purchase of a number of local telephone enterprises throughout the empire, at the estimated cost of £125,000. This money will be borrowed at 4½ per cent.

Rochdale.—At the last meeting of the Rochdale Town Council Councillor Fishwick hoped the Gas Committee would soon seriously consider the electric lighting. Alderman Petrie (chairman of the committee) said they were keeping their eyes on Manchester.

Nottingham.—Mr. Talbot's local knowledge of Nottingham is called in question by a correspondent of a Nottingham paper who does not like the "central site" chosen. A site at Radford or Carrington, with coal some shillings cheaper, would, he thinks, be far better.

Rhyl.—Mr. J. S. Greenhalgh has been protesting against the purchase of the gas works. Buy the winter garden, he says, and use the electric light. He states he shall resign his post on the Council if the vote goes against him, and offers £100 for to start a public subscription.

Art Fittings.—The beautiful electric light fittings which have been viewed with so much pleasure at the opening of the Junior Constitutional Club's new palatial premises in Piccadilly last Friday, were specially designed and manufactured by Mr. Roger Dawson, of 53, Berners-street.

St. Helens.—Alderman Cook (chairman of the St. Helens Gas and Lighting Committee), Aldermen J. C. Gamble and McKechnie, and Councillors Nuttall, Beecham, and Forster have been appointed a sub-committee to consider the question of providing a supply of electricity within the borough.

City and South London Railway Company.—The receipts for the week ending December 4 were £907, against £810 for the corresponding period of last year, or an increase of £97. The total receipts for 1892 show an increase of £1,824 over those for the corresponding period of 1891.

Town Mansions.—Messrs. Pyke and Harris, of New Tothill-street, have just finished the wiring and fitting of the Grafton Galleries, Grafton-street. They are also wiring 47, Gloucester-terrace, Hyde Park; also town mansion for Lord Montague, 9, Queen's-gate, South Kensington.

Teignmouth.—At the meeting of the Teignmouth Local Board last week the Rev. R. D. Maxwell and Messrs. F. Friend and Walton presented a requisition asking the Board to call a public meeting to discuss the questions of the extension of the gas works and the introduction of the electric light.

Windermere.—The Main Roads Committee of the Westmoreland County Council have resolved that it be recommended that leave to put cables under certain main roads for electric lighting purposes be granted Messrs. R. H. Fell and Son, Limited, Windermere, at the rate of 10s. per mile per annum.

Barnard Castle.—The Barnard Castle Local Board are considering a tender from the Brush Company. Mr. Smith, at the last meeting of the Board, gave some figures as to cost, and stated that enough water was escaping from the reservoir to run a 100 h.p. turbine. The matter was carried forward.

Sheffield.—A correspondent of the *Sheffield Daily Telegraph* urges the Corporation to take up the electric light question themselves at once. A committee, he says, not of gas shareholders, should be appointed to enquire into and report upon what is being done in other towns. He would willingly pay twice the present cost of gas.

Liverpool.—The Parks, Gardens, and Improvement Committee of the Liverpool Town Council [illegible] last week to allow the Electric Supply Company to put down their main in Sefton Park in order to supply the houses on the Corporation property where the tenants desired to substitute the electric light for the gas at present in use.

Windsor.—Mr. Evelyn Liardet has made a proposal to the Windsor Corporation to run the electric light installation by [illegible] new motor, and the proposal has been referred to the Water Works Committee. We advise the Corporation to obtain the services of a responsible and experienced consulting engineer, and to follow his advice.

Accrington.—The Accrington Town Council decided on Monday to apply to the Local Government Board for sanction to borrow £10,000 for the erection and equipment of a technical school, and for £10,000 for the purchase of land for the establishment of a central electric lighting station, besides £1,400 for the purchase of baths and washhouses.

Palace of Varieties Searchlight.—A large searchlight has been fixed upon the summit of the new Palace of Varieties, Shaftesbury-avenue, by Mr. Ronald Scott for Sir Augustus Harris. People must be on the look out for its beams sweeping round [illegible] and the light will serve as a beacon leading, we suppose, to the place of a very interesting entertainment.

Edinburgh Tramways.—The Corporation of Edinburgh are prepared to receive offers for a lease of the Edinburgh [illegible] tramways for a period of years to be arranged. [illegible] tenders and a skeleton lease embodying the conditions [illegible] upon by the Corporation will be forwarded to intending [illegible], on application to Wm. Skinner, town clerk, City Chambers, Edinburgh.

Reduction in Telephone Charges.—The National Telephone Company, Western Division, have given notice of a considerable reduction in the fees payable by their subscribers for communication on the trunk lines between the following places: Bournemouth, Boscombe, Christchurch, Southbourne-on-Sea, Poole, Southampton, Basingstoke, Winchester, Fareham, Gosport, and Portsmouth.

Alternating v. Direct.—There is one practical point to be noted in connection with Sir David Salomons's new machine, and [illegible] that once the opposite kind of machine proves practical and efficient, viz., for turning alternating into direct currents, we might very soon see the London Electric Corporation [illegible] courage and possibly having its erstwhile opponents once again on the hip.

Blackpool Conduits.—Tenders are required for excavating for and laying cast-iron pipes, and making good the streets for [illegible] electric light conduits within the borough, for the Corporation. Specifications and forms of tender may be obtained from the borough electrical engineer. Tenders to be delivered to Mr. Howarth, borough electrical engineer, Princess-street, Blackpool, by 14th inst.

Aston.—The success and popularity of the electric installation at the new baths at Aston has induced [illegible] the introduction of electric light throughout the district. The surveyor has been instructed to make enquiries from various places which have adopted electricity, and to embody the result of his investigations in a report for presentation to the [illegible] at an early date.

South London Extension.—The residents in the neighbourhood of The Swan at Stockwell are petitioning against the proposal of the Electric Railway Company to sink a shaft on the [illegible] and through which it is proposed to remove the [illegible] excavating the tunnels. A committee of the Lambeth Vestry proposed to give the company every facility, but in consequence of the objections of the inhabitants the matter has been referred back.

Wolverhampton.—The Electric Lighting Committee of the Wolverhampton Town Council will, we understand, recommend the Council next Monday to accept the tender of the [illegible] Construction Company, Limited, to supply the installation of the electric light within that portion of the borough which the Council have decided to light. The cost of the work will be about [illegible], exclusive of the cost of buildings which will be necessary for the machinery and other plant.

Portsmouth Tenders.—The Urban Sanitary Authority [illegible] tenders for the supply and erection of boilers, steam engines, condensers, steam and water pipes, pumps, overhead travelling traveller, electrical machinery, apparatus, etc. Copies of the plans and specification and form of tender can be obtained of Mr. Alex. Holland, town clerk, Portsmouth, on payment of [illegible] to be returned on receipt of a bona fide tender. Tenders to be delivered by January 5, 1893.

Taunton.—The electric lighting question at Taunton has [illegible] reached an interesting stage. Petitions were got up [illegible] inhabitants that the town, notwithstanding Mr. [illegible], should buy the present installation and carry it on. These petitions have been sent to the Board of Trade, and the result has been that an enquiry is to be instituted into the matter. As

and referred to the Works Committee, said it was not impossible that the lighting of the parish would sooner or later be done by the Dust Disposal Committee. Undoubtedly they would see that the dust of the parish was used to producing electricity whether they liked it or not. When he advocated what might be done with the dust consumed in a dust destructor he was laughed at. Mr. Hodges agreed with this and thought the cost of the electric light could be done away with by burning the refuse of the parish. The proposition of Mr. Brass was carried.

Reading.—At the monthly meeting of the Reading Town Council last week, the surveyor (Mr. A. E. Collins) reported that he had been in communication with the Reading Electric Lighting Company respecting the supply of current for lighting the large town hall. Their manager (Mr. Yeatman) told him at present his company could not supply current, their machinery being already loaded to its fullest capacity. He thought that if the arrangements now in progress for obtaining a provisional order and forming a company to supply electrical energy throughout the town proceeded satisfactorily current could be supplied in from 18 months to two years. The charge would be about 12s. per hour for current. The Town Halls and Markets Sub-Committee were instructed to reconsider and report to the committee on the subject of lighting the large town hall with electric light, or taking measures in some other way for protecting the timbers in the roof of the hall. At a subsequent meeting on November 24 the sub-committee reported that they did not at present recommend that any alteration be made in the lighting, especially in view of the probability of the Reading Electric Supply Company, Limited, being at a comparatively early date in a position to supply electric current to the Corporation for the purpose. The sub-committee, however, recommended that the timbers in the roof of the hall be painted near the gas jets with asbestos paint, and that the surveyor be authorised to provide shields to prevent the gas light blowing out, as now often happens. This report was agreed to.

City Lighting.—At the meeting of the City Commission of Sewers on Tuesday, the subject of the electric lighting of the streets came forward. Colonel Heywood, the engineer, said he had applied to the Gas Light and Coke Company with regard to utilising the existing lampposts in the side streets for incandescent lights in such a way that if the electric light should fail the gas would still be available. The company had replied, pointing out the difficulties under which they at present were carrying on the street lighting. They were being prosecuted by the City authorities for the impurity of the gas supplied to some of the lamps, which impurity was due to the presence of sulphuretted hydrogen owing to the stagnant gas in the disused gas pillars and pipes. Again, lamps were continually being lighted by unauthorised persons in consequence of the failure of the electric light, and by mischievous people passing on omnibuses. The loss arising from these practices was not so serious when the lamps were visited twice a day for the purpose of turning the lights on and off. The company thought the Commission would recognise the fact that they had done all in their power to facilitate the improved lighting of the streets even at considerable cost to themselves, and notwithstanding that the concessions made from time to time were in favour of an opposition mode of lighting. The company could not allow their fittings to remain as suggested, but they proposed, as soon as the lampposts were utilised for the electric light, to vacate them altogether. Colonel Heywood said that was a most important matter for the Commission. There would be no alternative supply in case the electric light should fail. The letter was referred to the Streets Committee.

From the "London Gazette."—The issues of the *Gazette* for November 25 and 29 contain much interesting information as to proposed work. The issue of November 25 has the following:

HARROGATE in its Bill takes powers to empower the Corporation to erect dynamos, engines, and other machinery for the generation and supply of electricity on the lands hereinbefore described and known as the Jenny Plain Farm or Irrigation Farm, and to authorise the Corporation to erect or lay down conductors, electric lines, and other electrical apparatus, for the conveyance or transmission of electricity from the proposed works to the borough, and for those purposes to break up and interfere with streets, highways, drains, gas and water mains and pipes, and in respect of the matters aforesaid, to confer on the Corporation all or some of the powers given to the Corporation by the Harrogate Electric Lighting Order, 1891, and the Electric Lighting Acts, 1882 and 1888.

BECKENHAM desires to obtain a provisional order for electric lighting.

CITY AND SOUTH LONDON RAILWAY ask for additional powers to obtain land for completion of railway and for other purposes.

BRIGHTON AND HOVE ELECTRIC LIGHT COMPANY ask for leave to bring in a Bill and to pass an Act for a variety of purposes connected with the supply of electric energy.

ST. MARY, ISLINGTON (NORTH), for a provisional order for the Holloway Electricity Supply Company.

TAUNTON also requires a provisional order.

COLCHESTER, among other things, asks for a provisional order.

BRIGHTON AND ROTTINGDEAN.—This Bill deals with a unique subject. It proposes to form a company and construct an electric railway from Paston-place groyne to Rottingdean. The following abstract from the *Gazette* notice will explain the views of the promoters. To make and maintain the railway, jetty or landing place, and works hereinafter described, or some part or parts thereof, with all proper stations, platforms, approaches, sidings, buildings, apparatus, generating stations and machinery, appliances, works and conveniences connected therewith, that is to say: 1. A railway commencing in the parish of Brighton, in the county of Sussex, near the Paston-place groyne, on land, beach, or foreshore, leased by

the Corporation of Brighton from the Crown, thence proceeding along the beach and foreshore on the level between high and low water mark, at a distance of about 100 yards from the cliff, to the village of Rottingdean, and terminating at a point on the seashore immediately to the westward of Rottingdean Gap, in the parish of Rottingdean. 2. A jetty, or landing stage, commencing at the termination of the before mentioned railway in the parish of Rottingdean, and proceeding thence in a southerly direction over the foreshore and into the sea for a distance of 200ft., or thereabouts, and terminating in the sea. It is intended that the railway shall be constructed on a gauge of 24ft., and that the carriages to be run thereon shall be moved by electricity or mechanical power, and that the platforms or bodies shall be placed at such an elevation as to be safe from interruption by the sea.

BLACKPOOL, ST. ANNES, AND LYTHAM require an extension of tramways which would probably be worked electrically.

WEST METROPOLITAN TRAMWAYS COMPANY require further powers and, among others, for the use of electric traction.

HAMMERSMITH applies for a provisional order, as does HUTTERSFIELD, and ditto ALTRINCHAM and BOWDON, on behalf of the Manchester Edison Swan Company.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY desire confirmation of an agreement transferring some of the powers of the Chelsea Electricity Supply Company, and other powers.

NEWMARKET.—The British Electric Light Company ask for a provisional order for Newmarket.

SALFORD introduces a Bill to construct tramways which may be worked electrically.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY requires further powers for extensions and alterations.

The *Gazette* of Nov. 29: ISLINGTON.—The County of London Electric Lighting Company ask for a provisional order.

BRIGHTON.—Brighton and Hove Electric Lighting Company. Provisional order to supply within the borough of Brighton and the parish of Preston.

BIRMINGHAM.—Central (Cable) Tramways. Construction of tramways with power, among other things, to use electric traction.

Chelsea.—Mr. T. W. E. Higgens, A.M.I.C.E., the surveyor to the Vestry, has reported upon the proposed Clapham and Paddington Railway. The report deals fully with the whole matter, and the possible disturbance, as well as value to his district. The remarks made in the report dealing with electric traction, if used, are as follows: "It must also be borne in mind that the description of car to be used on this line will differ very considerably from that used on an ordinary railway. The weight of a train on the District Railway when loaded with passengers is said to be about 200 tons, whereas a loaded train on the South London Electrical Railway is said to be only 40 tons. It is quite possible that the trains to be used on the proposed Clapham Junction and Paddington Railway may be less than that, if the motive power is cable power instead of electricity. The clause in the *Gazette* notice dealing with this matter says: 'The motive power to be employed will be cable power or electricity, or such motive power (other than steam locomotives) as the Board of Trade may approve,' but I think it is highly probable that electricity will be used, as the principal engineer to the scheme is Mr. J. H. Greathead, who constructed the City and South London Electrical Railway, which is the pioneer railway of its kind. If the motive power is electricity, and cars of a similar description to those on the City and South London Railway are used, I should think that the passing of an ordinary builder's cart will shake the houses far more than a passing train. As regards the Square gardens, the promoters are clearly asking for an easement, and one which they could not expect to obtain for nothing. It should, however, be said that the passing of trains under the gardens will

in any way interfere with their use by the public, and as the public will eventually be benefited if the railway is made, I would suggest that the Vestry ask the agent to the promoters to confer with them as to the annual rental to be paid by the company for the privilege of passing under these gardens."

Coventry Tramways.—At the last meeting of the Coventry City Council the Mayor (Mr. Singer) moved the adoption of the report of the General Works Committee with reference to the proposed introduction of electric traction on the tramways. The system proposed by Mr W. S. Graff Baker, the owner of the tramways, is that known as the Thomson-Houston overhead-wire system. While admitting that in the matter of efficiency the system left nothing to be desired, the Mayor contended that the overhead wires were very detrimental to the appearance of the streets, and on that ground they ought not to consent to the introduction of the system into the narrow streets of Coventry. A letter was read from Mr Baker commenting, by the way of reply, upon the General Works Committee's report, and stating that the appearance of the wires at Leeds bore no resemblance to the wires and supports as they would be constructed in Coventry. The Mayor said the proper policy was to wait. Alderman Tomson seconded the motion, referring to the very ugly and offensive erections overhead. In wide streets they were bad enough, but in narrow streets they would be still worse Alderman C. J. Hill opposed the report so far as the eighth clause was concerned, which recommended sanction to the temporary use of steam, to which he was opposed most strongly He proposed that the report be referred back to the committee to deal with the point. Alderman Farish seconded the amendment, which was lost by a large majority. Mr. West said he was not at all satisfied with the report. He strongly supported the electric tramways and reminded the Council that only seven months ago the Coventry Corporation cursed steam tramways in the heartiest manner, and asked for electricity; now the General Works Committee objected to electricity and proposed to approve of steam. He moved that the matter be referred to the Council in committee. Mr Lee, in an animated speech, supported the amendment, remarking that the system was giving every satisfaction in Leeds. Alderman Tomson having spoken, Mr Loudon said: If it was to be a question of steam or electricity with overhead wires, then, by heavens, let them have electricity! He contended that the matter had not received fair treatment in the General Works Committee. Alderman Marriott, as chairman of that committee, strongly protested; and Mr. Andrews, in supporting the report, objected to the attempt to force the hands of the Council The question was discussed at great length in an animated and excited manner. Ultimately, the Mayor said the whole question was one of the unsightliness of the overhead wires, and announced that Mr. W. S. Graff Baker was prepared to erect poles and wires along a portion of the route to give the Council an opportunity of judging, and the matter was then adjourned.

Nottingham.—The Special Committee appointed to deal with the electric lighting of the borough have prepared the following report, which was presented to the Town Council at their meeting on Monday: "That the delay which has taken place since their last report was presented to the Council in November of last year has been used by your committee for the purpose of carefully considering what steps the Town Council should take to carry out the electric lighting of the town, and of obtaining information to guide them in the course which should be adopted with respect thereto. Your committee have made themselves acquainted with the method of electric lighting used in various towns in the provinces, and in London and its suburbs. The electrical engineer, Mr. H. Talbot, has been engaged under the direction of your committee in making himself acquainted with the whole of the central portion of the town, with the view of advising as to the best method of supplying it with electricity. Mr. Talbot's report is printed in the appendix. Mr. Talbot recommends the low-pressure continuous-current three-wire system, in combination with the high-pressure continuous-current and transformers. Your committee have had some anxiety with regard to a site for a central station. They advertised in the local papers, and the most suitable site which has been brought under their notice is that mentioned in the report of the engineer—viz., the site between Talbot-street and Wollaton street, known as 'Holborn Villas' This property can be purchased at the price of £3 12s. 6d. per yard They are of opinion that the price is fair and reasonable. They therefore advise the Town Council to authorise them to conclude the purchase of the above site for the purposes of an electrical station The whole of the land will not be required at once, but it is only prudent to make provision for the future extension of the works The Council will see that the total estimated outlay is as follows:

Land in Wollaton-street	£10,175
Capital outlay, buildings, plant, mains, etc.	34,580
Total	£44,755

Your committee strongly recommend that the above purchase should be completed, and that the necessary plans, drawings, and specifications, as set forth in Mr. Talbot's report, should be put in hand for the building and plant required for a central station, and that the consent of the Board of Trade should be obtained, and that your committee be authorised, as soon as such consent is obtained, to advertise for and accept tenders for the execution of the necessary works, and that your committee should be authorised to take all such steps as may be necessary to give effect to their recommendations. Dated this 15th day of November, 1892. John Turner, chairman. The engineer's report is as follows: 'Gentlemen,—I have the honour to report that after mature and careful consideration of the question as to the best means of supplying electrical energy to the town of Nottingham, under the Nottingham Electric Lighting Order, 1890, and having due regard to the probable requirements of the town as to the use of electrical energy both for lighting purposes and for motive power, I beg to advise the adoption of the low-pressure continuous-current three-wire system, as being the most suitable and convenient for meeting the demands of a manufacturing town. But to make this system more economical and able to supply distant and scattered areas, such as the park and the north-east portion of the town, I advise the use of high-pressure continuous currents, with continuous-current transformers and batteries. This latter part of the system could be added when required. With a low-pressure three-wire system an area of one and a half miles diameter can be supplied from one generating station, providing the station is near the centre of the area; but by using transformers the area can be increased to two miles On inspecting the town with a view to the selection of a site suitable for a generating station, I find that the only one available in a central position is that lying between Wollaton-street and Talbot-street, and known as Holborn Villas. This site contains about 2,800 square yards, and is most central. By taking this as a centre and describing a circle of three-quarters of a mile radius (which is the practical limit of a three-wire system) it extends to Hardy-street on the north-west, Emmanuel Church on the north-east, Sneinton Market on the east, Bloomsgrove-street on the west, and Waterway-street on the south. I advise that the buildings at the generating station should be at first designed to contain sufficient plant for supplying electrical energy for 13,000 8-c.p. lamps, but plant should only be put down for 10,000 lamps. This would add but little to the expenditure, and would enable more plant to be put down when required without having to extend the buildings. The buildings to be so designed and constructed that should necessity arise they can be extended at any time without interfering with the working of the station. The chimney should be built of sufficient capacity to be able to accommodate boilers capable of generating steam for supplying at least 20,000 8-c.p. lamps, as the extra cost entailed in building a large chimney would not be so great as building a second one when an extension of the plant becomes imperative. I advise the use of Galloway or Lancashire boilers, with a feed-water heater. This apparatus, by utilising the heat of the exhaust steam, raises the temperature of the feed water to about 200deg. F., and the condensed steam can be used in the boilers, thus saving coal and water, and in addition preserves the boilers to a great extent from incrustation. Willans central valve engines are in use at most of the electric light stations in England, and from my experience I consider them to be economical, and to cost no more for repairs than any other type of high-speed engine. There are some good open type vertical engines made by Davey, Paxman, and Co., of Colchester, and Belliss and Co., of Birmingham. The former are being used at one of the London stations, and the latter have been selected for the central station at Preston, but having had no experience with these particular engines I cannot speak of their efficiency. I advise that the dynamos should be tendered for by the best-known makers, and that in the specification there should be clauses to the effect: 1. The contractor to state the amount of water he will guarantee shall not be exceeded per electrical horse-power at dynamo terminals per hour. 2. The dynamos to be subjected to eight hours' continuous run at full load at the contractor's works in the presence of the Corporation electrical engineer. 3. At the end of the run to pass the Admiralty specification as regards heating, etc. These must be laid in all the streets mentioned in the second schedule of the provisional order, and known as the 'compulsory area,' and in other streets when required, in compliance with the Nottingham electric lighting order. Low-pressure mains are usually of bare copper strip carried on insulators in concrete culverts under the footways. This system has the advantage of being cheaper than any other when large mains are necessary, but for small mains the cost is about the same as for insulated cables. The disadvantages of bare copper mains are: 1. The work takes longer to execute, and, therefore, causes greater inconvenience in busy thoroughfares. 2. Precautions have to be taken to keep the culverts free from water or gas. I advise that bare copper should be used where large mains are required, and that insulated cables drawn through iron pipes, or other approved conduits, should be used where only small distributing mains are necessary; and to ensure a good and efficient system of mains, the contractor should be required to keep the same in a satisfactory condition at his own expense for a period of three years after the completion of the work, and at the expiration of that time the Corporation to take them over only on condition that they pass the test as mentioned in the specification. These should be tendered for by local engineers. I advise that a five-ton traveller should be erected in the engine-room to facilitate the erection and dismantling of machinery. I do not advise the use of more batteries than are absolutely essential for the economical working of the station, and consider that one capable of supplying 1,000 8-c.p. lamps would be sufficient to guard against a sudden breakdown of machinery, and to supply current without running the machines during the hours of small demand. A small battery would be required for the park district should there be a large demand. Whatever type of battery is used should be maintained by the contractor in an efficient state, at a reasonable rate, and for a lengthened period. These should be tendered for by well-known contractors. There are several kinds of meters in use at the present time, but none of them have as yet been certified by the Board of Trade. Probably before a meter is required in Nottingham the Board of Trade will have certified

some. I estimate the capital outlay on buildings of sufficient size to accommodate plant for 13,000 8 c.p. lamps, and generating plant, mains, meters, etc., for 10,000 lamps at £34,580. The site in Wollaton-street contains 2,807 square yards, and at 72s. 6d. per yard will cost £10,175, making a total expenditure of £44,755. The approximate cost of working a central station of 10,000 8-c.p. lamps, including maintenance and depreciation, and assuming that the whole of the lamps will be in use for 600 hours per annum will be £3,509, and the revenue derived from 10,000 8-c.p. lamps, assuming that each lamp is in use for 600 hours per annum, and 6d. per Board of Trade unit is charged, will be £4,950—showing a profit of £1,441, or 4 per cent. interest on the cost of the installation, exclusive of the land. The revenue from the same number of lamps if in use for 700 hours each per annum, will be £5,775, and the approximate cost of working the station for supplying 10,000 lamps for 700 hours per annum will be £3,587, showing a profit of £2,188, or 5½ per cent. interest on the cost of the installation, and a proportionate part of the capital (viz., £3,500) expended on the site. It is found in practice that only three fifths of the lamps installed are ever in use at one time, so that it is perfectly safe to connect 16,000 lamps to the mains of a central station having machinery capable of supplying 10,000 lamps. If 16,000 lamps are so connected and are used for 600 hours per annum, the revenue from same will be £7,920, and the cost of producing the electrical energy, including maintenance and depreciation, will be approximately £3,789, showing a profit of £4,131, or over 10 per cent. interest on the cost of the installation, including a proportionate amount for land. It will be seen from the above statements that the cost of running 10,000 lamps for 700 hours per annum is only £78 more than for running the same number of lamps for 600 hours. This is accounted for by the fact that in both cases the standing charges for depreciation, maintenance, and wages are practically the same, and the extra cost is for coal, water, and stores. It therefore follows that as the number of lamps in use increases the cost of production will decrease. The local authorities which have adopted electric lighting are St. Pancras Vestry, Brighton, Bradford, Glasgow, Dundee, York, Oldham, Hull, Manchester, Bristol, Worcester, Portsmouth, Southport, Burnley, Hanley, Aberdeen, Derby, Whitehaven, and Blackpool Corporations.'" The consideration of this report was postponed to a special meeting.

PROVISIONAL PATENTS, 1892.

NOVEMBER 28.

21693. **An improved electrical meter and recorder.** Pierre Feys and Jean Lorwa, 97, Newgate-street, London.

21696. **Improvements in electric smelting of aluminous and other refractory ores or compounds.** Thomas Leopold Willson, 55, Chancery-lane, London.

21701. **Improvements in the reduction or treatment of refractory metallic compounds by electric smelting.** Thomas Leopold Willson, 55, Chancery-lane, London.

21703. **Electric apparatus for illuminating the sights of firearms in the dark.** Giovanni Garassino di Giovanni, 28 Southampton-buildings, Chancery lane, London

NOVEMBER 29.

21750. **Improvements in means or apparatus for use in typewriting, or typewriting inter-communication with the aid of electricity.** Albert David Neal and Howard French Eaton, 55, Chancery-lane, London. (Complete specification.)

21782. **Improvements in electrical resistance coils.** Siemens Bros. and Co., Limited, and John Nebel, 28, Southampton-buildings, Chancery-lane, London.

21794. **Improvements in the manufacture of electrodes for ozonisers** Emile Andreoli, 18, Somerleyton-road, Brixton, London. (Complete specification.)

21803. **Improvements in electric transformers.** Charles Eugen Lancelot Brown, 46, Lincoln's-inn-fields, London.

21811. **Improvements in multiphase alternating-current meters without separate excitation.** Charles Eugen Lancelot Brown, 46, Lincoln's-inn-fields, London.

21830. **Improvements in apparatus connected with flexible electrical conductors and in electrical connections therefor applicable for use in mines.** Claude William Atkinson and the Electrical Coal-Cutting Contract Corporation, Limited, 1, Queen Victoria-street, London. (Complete specification.)

NOVEMBER 30.

21874. **Improvements in electric light and other pendants.** Harold Lyon Thomson Lyon, 59, Chancery-lane, London.

21906. **An electric alarm of danger from fire or water.** Alex Liedcke and Paul Jacobi, 28, Southampton-buildings, London.

21919. **Improvements in the method of making electrical connections and disposition of circuits carrying induced currents.** Camillo Olivetti, 150, Holland-road, Kensington, London.

21940. **Improvements in or relating to multiple telephones.** Leonard Prosper Moreau and Claude Joseph Augustin Munier, 323, High Holborn, London. (Date applied for under Patents Act, 1883, sec. 103, May 28, 1892, being *date of application* in France.)

DECEMBER 1.

21951. **Improvements in the manufacture of porous earthenware pottery articles for electrolytic purp[illegible]** William Allen, Benthall Pottery, Broseley, Salop.

22001. **Improvement in incandescent electric lamps (4[illegible] filament).** Louis Hendle and Edward Russell Cum[illegible] 95, Finsbury-pavement, London.

22034. **Improvements in and in connection with electri[illegible] meters.** Gustav Binswanger, 11, Furnival-s[illegible] London.

22035. **Improvements in electrical switches and other [illegible]** Gustav Binswanger, 11, Furnival-street, London

22038. **Improvements in and relating to stands for incand[illegible]cent electric lamps** Josef Cathrein, 45, Southamp[illegible] buildings, Chancery-lane, London.

DECEMBER 2.

[illegible]. **Improvements in or in connection with an ele[illegible] motive power system.** Wilfrid L. Spence and Stewart and Co., Limited, London-road Iron W[illegible] Glasgow.

22085. **A varying price electric supply meter.** John Pe[illegible], Brunswick-square, London.

22087. **Electrical variable resistance apparatus.** John Al[illegible]ander Colquhoun, 67, Gibson-street, Hillhead, Glasgow.

DECEMBER 3.

22129. **An improvement in electric switches for curren[illegible] high potential** Charles Joseph Wharton, 38, Pa[illegible]ment street, London.

22131. **An insulating material for covering electric and te[illegible]phone wires, bicycle tires, and carriage [illegible]** Frederick Walter William Goodsall and Hasting [illegible] Wright, 40, Holborn viaduct, London.

22164. **Improvements in or relating to electrical [illegible] high-tension currents** George Hinde N[illegible] Chancery-lane, London.

22187. **Improvements in lightning arresters.** Reginald [illegible] 28, Southampton-buildings, Chancery-lane, [illegible] (The Westinghouse Electric and Manufacturing [illegible], United States.)

SPECIFICATIONS PUBLISHED

[illegible]

10273. **Dynamo-electric machinery.** Desroziers. (Sec[illegible] edition.)

1891.

16041. **An improved coupling for lightning conductors.** Lewis, 3, Great Winchester-street, E.C.

17042. **Dynamo-electric machines.** MacHaffie.

19134. **Electric meters.** Teague.

19972. **Telephone circuits.** Mayer.

19973. **Electric arc lamps.** Maquaire.

19996. **Electric alarum clocks.** Nicholls.

21427. **Water filters and cisterns.** Parker.

NOTES.

Tramcar Brake.—The attempts to use a tramcar brake with spring useful for starting the car, are reported successful.

Royal Institution.—Among the lecturers before the Royal Institution next session are Lord Rayleigh, Prof. Dewar (on "Liquid Air," January 20, 9 p.m.), Mr. Alex. Siemens, and Dr. Ed. Hopkinson.

Military Lamps.—The lamps used under the auspices of the Berlin Electrical Society for military manœuvres at Templehof were of 50 c.p., run by a battery weighing 17½lb. The light lasted some hours, and was sufficient to distinguish persons at the distance of 100 yards.

Tramway v. Telephone.—The important case between the National Telephone Company and Mr. Graff Baker, which is to decide the vexed question of interference between electric trams *v.* telephones, has been partly heard by Mr. Justice Kekewich, and the further hearing is adjourned till January 11.

Secondary Batteries.—Streintz, in his experiments on secondary batteries, is said to have proved by measurements of the E.M.F. the presence of hydrated peroxide of lead as a secondary product on the plates, and considers that its formation is accompanied by a diminution of E.M.F. of the element of charging and its destruction by a corresponding increase on discharging.

The New Westinghouse Lamp.—Already prior claims are made to the peculiar details in use in constructing this lamp. Dr. Böhm, in our contemporary the *Electrical World*, deals with the history of separable incandescent lamps, and says that the feature of the Westinghouse lamp covered by patents must have reference to patents granted to Farmer, Maxim, and to himself. He is also of opinion that the ground-glass stopper "will not hold the vacuum for the required length of time."

Electric Interlocking Signals.—Major Yorke, in his report to the Board of Trade on the Kentish Town accident, says: "Regulations of the most careful and satisfactory nature may be drawn up, but absolute compliance with them cannot at all times be ensured, and I would suggest for the consideration of the company whether it would not be possible to adopt on busy sections of the line some system of electrical interlocking which would prevent a signalman from lowering his starting signal without the permission of the man in the cabin next in advance."

Electric Traction in New York.—Great interest is being excited over the question of electric traction for New York. It is thought that the Philadelphia and Reading Railroad may obtain control of the underground rapid-transit system, and that if this is the case that electric traction would have an opportunity of being tested against steam. Electricity and steam would be run under the same management, and the trouble with the smoke in the tunnels might lead to the establishment of heavy electric locomotives throughout to do the hauling in the tunnels.

Charging Accumulators.—A novel method of charging accumulators on a central station is mentioned by *Industries* as in use at Genoa. A force of 100 h.p. is available during the whole 24 hours, by which two dynamos giving 275 amperes and 115 volts each are driven during the evening. These dynamos in series supply 1,100 16-c.p. lamps. During the day no use is made of the water power, and it has been decided to make use of it for charging accumulators. An installation has been made of 126 Tudor accumulators. As it was not convenient to put in new dynamos, the reserve dynamo used in connection with the other two gives the necessary voltage for charging.

Transmission of Power in Italy.—The industry of electrical transmission of power seems to be making rapid headway in Upper Italy under the influence of the Italian Electrical Society. The great natural resources of the country lend themselves very much to the spread of the industry, and in Milan alone there are 18 installations for electric power, though not of very large amounts. The Alzano waterfall is to be used for distribution, 50 h.p. at three miles, 40 h.p. at half a mile, and 180 h.p. at a quarter of a mile or so. At Pavia power is transmitted from Gravellone 500 yards to the extent of 200 h.p.; while in the province of Navarre the society is laying down a transmission plant of 1,000 h.p. to transmit from Cassagno to Intra, a distance of about six miles.

Telephonic Combination.—The great telephonic competition promised to the metropolis has fallen through, and the National Company has practically won hands down. The result has not been unexpected since the practical agreement of the two concerns; and if the promise to amend its ways and its circuits is carried out, this result may be beneficial. Our controversy with the National has been upon two points—finance and service. The service will have to be made more perfect or troubles will again arise. We shall be interested, perhaps amused, to learn what is the position of the people who have signed on with the New Telephone. Was the printed form of the nature of a contract, or was it provisional and not binding? If it was a contract, does the National take it over?

Electrolysis.—In an abstract from the Chemical Society's *Journal*, Freudenberg is said to have shown a new principle of electrolytic separation of metals. According to Le Blanc, in a solution the amount of the electric charge is identical for one and the same ion, and that, therefore, the point of decomposition of an electrolyte may be exactly determined. As this value differs very considerably for the various metals, the author thought it probable that their separation may be brought about by employing currents of different E.M.F.'s, and the experiments already made show that such is really the case. Thus with a single Leclanché cell, having an E.M.F. of 1·35 volts, silver may be separated from copper and bismuth, and mercury from copper, bismuth, and arsenic. The analysis given show a very close agreement with the theoretical numbers.

Champs Elysees.—One would have thought that electricity would have penetrated the charmed region of the Champs Elysées at Paris long ere this, but it seems not. The central station which is to light the triple boulevards, concert grounds, and the magnificent mansions of this favoured quarter of the gay city is, it is true, now completed. The wiremen are busy in the district, and the light will soon be turned on. The central station is placed on the border of the Seine, and there is some talk of a generating station for an electric railway from the Port Maillot to Suresnes. The same insane hostility which proposed industrial developments of this kind have met with in London, is found also in Paris. There is no real reason, however, to suppose that Paris will not have its cleanly electric railway below as well its cool and brilliant light above the ground.

Waterloo Signals.—The paper of Mr A. W. Szlumper, M.I.C.E., on the signalling at the Waterloo Terminus, which has recently been issued as a selected paper in the Institution of Civil Engineers' *Proceedings*, describes a marvellously ingenious system of signalling. Both mechanical and electrical parts of the apparatus are simply described and amply illustrated. The attempt is to construct a sys-

tem of signals so perfect as to prevent the possibility of accident either by misadventure or intentionally. The apparatus is at once complicated and simple, if that be possible. In place of the ordinary block system the Sykes electric lock and block has been adopted throughout, and specially arranged for terminus working. Visual and audible signals are given. Here the electrical working of the absolute block system is combined with the mechanical working of the outdoor signals, controlled by the movement of trains passing over treadles fixed to the rails, rendering it practically impossible for a wrong signal to be given.

Cold and Ether.—Says a science note in the *Daily Chronicle*: "That extreme cold paralyses every vital function is, of course, a piece of every-day knowledge. But it has been left to Prof. Pictet, who has been conducting some experiments on this subject, to discover that at a temperature of 150deg. below the centigrade zero there is no chemical action between nitric or sulphuric acid and potash, or between oxygen and potassium, though under ordinary circumstances the affinity of the latter metal for oxygen is so great that it will burn if thrown into water, owing to its combination with the oxygen in that fluid. But if the electric spark is played on bodies which have thus lost the power of chemical affinity, some new and curious combinations result. The latest investigation, the conclusions of which, however, have been theoretically presaged for some years past, may require us to reconsider the question of the temperature of outer space, and the possibility of an atmosphere composed of gases in combination existing there."

Patin Alternators and Transformers. — An account is given in *Electricit* for December 8 of the new type Patin alternators and transformers. The improvements in the dynamo relate more particularly to the field magnets, means being taken to form an inner and outer pole, the armature being in the form of a thin drum composed of many flat coils. Their running is very regular under great variations of load, and in one of these machines driven by a turbine furnished with a Picard regulator, the variation of voltage when the load is thrown off suddenly is only 2 per cent. The transformer is in the form of a rectangular box with closed magnetic circuit, the secondary coils being placed next the iron; the magnetic circuit is composed of sheets of iron made up in the form of two wide superposed tubes into which the copper wires pass, the iron discs being U shaped and built up in pairs. The magnetic circuit thus made is very good, and the putting together is easy. The efficiency of the transformer at full load is, it is stated, over 95 per cent., and the absorption empty is very low—"hardly amounting to 2 per cent."

The Wattmeter Method of Testing.—Dr. Sumpner rather astonished the whole meeting, including Dr. Fleming, at the Institution last week by stating, with reference to the wrong wattmeter readings in the celebrated transformer tests, that the explanation was one already given by Dr. Fleming in an investigation some six years ago, in the different behaviour of alternating eddy currents in a metal plate suspended near the coils. From two wrong readings he had been able to calculate seven or eight other wrong readings, which agreed with Dr. Fleming's results. The effect of the lag in the eddy currents was to make the reading greater with a condenser and less with a choking coil. To prove the matter experimentally, he had taken readings with a wattmeter with and without a suspended plate near the coils. The result was with a condenser, true watts 35, with plate near, 146 watts. With a choking coil, the true watts were 105; and with a plate near, 73 watts—showing the rise in one case, and the fall in the other. Dr. Sumpner promised a full working out of his note to the published report in the *Journal* of the Institution.

Automatic Letter Express Delivery.—The Post Office has just placed in front of the Royal Exchange, as an experiment, an automatic box which is intended to be an adjunct to the express delivery of letters and parcels. By dropping a penny in a slot the purchaser obtains an outer envelope, enclosing a small white envelope and one on which the desired communication may be written, resting upon a small desk which falls from the front of the box. At the same time an electric bell calls a messenger from the nearest post office, which is Threadneedle street. If it be desired to forward a parcel by express delivery, the arrival of the messenger must be awaited, but a letter may be deposited in the message receptacle for immediate despatch. The necessary fee has in each case to be enclosed in the envelope bearing the name of the addressee, and should the payment be insufficient, he will be required to pay simply the difference. For this service ordinary postage is not charged, and the fees specified in the case, which are at the rate of 3d. per mile, include the cab or omnibus fares. If the sender requires a cab to be used, the fare must be enclosed in the outer envelope, which has to be marked "By cab." If the convenience thus provided be appreciated at the Royal Exchange, the authorities of the Post Office are prepared to introduce it in many other centres.

Fire Risks.—In continuation of its articles on electric fire risks, the *Review* this week deals with Mr. Heaphy's suggestion of earthing one wire, and disagrees with the proposal entirely. With regard to proper wiring the insurance paper goes on to say: "In our opinion, arguments based on installations such as are made at the exhibitions are fallacious and worthless. They only show the thing at its very best. All the scientific conditions are complied with, and the work is executed in a manner which no doubt does, and is intended, to defy criticism. It is when we come to the ordinary run of work that the trouble begins, and our friend the wireman appears on the scene with his spirits of salts and his unsoldered joints. He is the real master of the situation. We would suggest that, instead of discussing the system, individuals should be looked after. 'The Wireman, and How to Deal with Him,' is a subject which we commend to the electrical experts, more than the merits of different mechanical systems." As long as it is open to any plumber or bellman to open up a branch department and hang out a sign "Electric wiring cheap," we shall continue to have danger from this source; and as long as there are firms who will take installations at any price, there will be a probability of employing bad workmen. The remedy is competent inspection and periodic testing.

Arcas Plating.—The ordinary silver has a slight addition of copper to produce the requisite hardness, and the substitution of other metals in place of copper has been the object of the London Metallurgical Company, whose process of hard silver, or "Arcas" plating, was demonstrated before the Press last Friday. The combination of several metals with silver has been tried with varying success, but by far the best result seems to have been obtained by the use of cadmium. Using a 10 per cent. addition of this metal a brilliant and very hard deposit is formed in electroplating, of a colour indistinguishable from that of pure silver, and with the advantage of taking a high polish, not subject to slight scratching and also of remaining untarnished on exposure to air. The advantages of "Arcas" are great

for most ornamental fittings, and it has been applied to shop fittings, silver plate of all kinds, harness and bicycle parts, and to lamp fittings. Several electrical fitting manufacturers testify to the satisfactory character of the Arcas plating, and we feel sure a very wide field of usefulness is open to the process. The workshops of the company are at 80, Turnmill-street, near Farringdon-street Station, where the plating can be seen in progress. An application of considerable importance in electric light is that of brilliant plated reflecting mirrors whose surface is practically unaffected by the heat or atmosphere.

Niagara.—On Wednesday, at the Society of Arts, Prof. G. Forbes read a paper on the utilisation of Niagara. Of course, as our readers well know, this utilisation is by means of electricity. We can only give Prof. Forbes's excellent paper in brief. The watershed drained through Niagara is about a quarter of a million square miles, so that the flow is practically constant. Suggestions for utilising the immense water power have been many times made, and, in fact, some partial use is made by means of a canal. The introduction of electric transmission, however, changed the course of ideas, and the Cataract Construction Company is working to utilise the hitherto wasted power electrically. Shafts and tunnels have been constructed which will allow the utilisation of about 100,000 h.p. by means of turbines, the turbines being of 5,000 h.p. each. Prof. Forbes stated that while he could speak definitely of the hydraulic work, he could not do the same for the electrical work, which was really under consideration, he having before him 20 distinct plans of the 5,000-h.p. generators which may be used. The remaining portion of the paper was devoted almost exclusively to a rapid review of the good and bad points of the various systems proposed, the tendency seemingly being towards the use of alternate currents and transformers. The author stated that his mind was perfectly open, and he was still able to consider any plan which might be placed before him.

Lighthouse Intensities.—When the Commissioners of Northern Lighthouses made an investigation to determine the luminous intensities of various lighthouses with the view of attaching definite values to them, they found that the intensities hitherto accepted were all too high, and, further, that with revolving apparatus no advantage is gained by increasing the flame beyond certain limits, which seem pretty nearly attained in "four-wick lamps." The policy apparently seems justified by recent results, as it is recorded that "the large burners adopted have been shown by experiments to be not worth the additional expense." Nothing appears to have been said on the value of electric light, and, as is well known, its value has been called in question in time of fog. For a subject of the importance that this must always be to a maritime nation, it seems time that some more settled attitude should be come to upon the whole subject of lighthouse illumination. No doubt the Commissioners have expert information of their own in their possession, but the various hesitations that are apparent, and the disasters which still so often occur consequent on misunderstanding of the penetrating power of light, seem to indicate that the matter might still be settled in a more scientific manner. An exhaustive paper on the subject of lighthouse illumination, dealing with the whole question of high-power light rays in the manner of other investigations that have been undertaken by Cantor lecturers, might prove of lasting utility.

Railway Accidents.—The return just issued by the Board of Trade for the nine months ending at September carries some points within it of importance to the electrical industry. As these may escape consideration unless notice is specially drawn thereto, we would invite the attention of electrical engineers, more particularly those likely to be engaged in traction work, to one matter in the report. It is this, that in the list of accidents which have befallen passengers in connection with railway travelling, 18 passengers were killed and 61 were injured by slipping between the carriages and the platform, including 15 killed and 26 injured while getting into trains. Compared with the number who suffered in railway accidents—12 killed and 476 injured—during the same time, it is clear that there is more real danger to life in getting in and out of the present carriages than there is in making the journey. There is, in fact, a want of proper precaution or means of averting danger at the platforms. We may leave to others the task of urging the necessary reform in carriage doors, footrails, and height of platform of the present railways; but considering the large increase of railway travelling which is likely to ensue by the introduction of electric traction on railways of various kinds during the next few years, we believe it our duty to point out this regrettable loss of life, and to insist that full and proper measures of safety should be taken in all new lines and at all new stations. It should be easy for engineers of electric railways to obviate this annual holocaust of unwary passengers.

A Non-Commutator Dynamo.—Under the title of "A New Method of Field Excitation," Mr. H. L. Tyler (in the New York *Electrical Engineer* for December 7) describes a dynamo of novel design, which he regards as obviating several defects of the present form. For a long time he has been working at a machine to reduce the cost, the complication of parts, and the sparking, and one has been produced embodying the points desired. The dynamo is of the stationary armature type, and the method of exciting the inner revolving field constitutes the novel feature. The exciting current is fed through a pole-changer commutator (the commutator in the ordinary sense being done away with entirely). The "changer" receives an alternating current, and alternately feeds the fields, the four sections of each ring being the terminals of the field coils, and not for the purpose of delivering the current in a continuous direction. The pole-changer delivers the current practically in the same state (alternating) as it is received. The revolving fields are in the shape of a thick cross wound so as to give a N pole at one arm and S pole at the next, so that two similar poles are at opposite ends of the cross. The lines are forced outwards at the N poles and drawn in at S poles, the poles reversing at the quarter-turn, keeping always the same relative polarity. "This method of field excitation," says Mr. Tyler, "at first appeared impracticable, but I have tested it with gratifying results. There is no sparking whatever even on a dead short circuit. The dynamo is made absolutely noiseless by a thin non-magnetic casing encircling the fields. There are any number of ways to place the armature coils, but it appears unnecessary to designate them. The general nature of the machine admits of first-class construction at a surprisingly low cost, and its high efficiency and simplicity are among its best recommendations."

French Submarine Cables.—A description, with illustrations, is being given in *Electricité* (November 10, 24, December 1, 8) of the manufacture of submarine cables at Calais. The Société Générale des Téléphones, whose factory is thus described, purchased the "Westmeath" to lay their cables, rechristening the vessel the "François-Arago." The principal cable laid is that from Marseilles to Oran, of which we have already given some particulars. The total length of this cable is 592·61 nautical miles (1,097·5 kilometres). The total resistance of the core is

6,363 ohms, or 10·74 ohms per mile. The capacity, after two minutes, is 142·3 microfarads; and the insulation resistance is 11,861 megohms per nautical mile. The Telephone Society only makes and lays cables, but will not interfere with the working. This lies with the Société des Télégraphes, whose cables are claimed as twelfth in importance out of 28 private companies. These cables are of small length, but of an importance which increases. They unite the Antilles with South America, an advantageous position. Suppose a message from Rio to New York. By the Brazilian Company it would go from Rio to Pernambuco, thence to Madeira, thence to Lisbon, and from there to London, finally to New York—a total of five transmissions, and a distance of 8,000 miles. With the French cable the message would go to Vizeu, and thence sent direct to New York—three transmissions and 3,000 miles—taking one day only, instead of two or sometimes three. In 1890 the Société des Télégraphes obtained the privilege of landing at Brazil cables from United States or Antilles, and has the overhead lines of Brazil to its own lines, and it is expected that the North American lines will also soon be connected. It will be remembered that, after much diplomacy, the society obtained on June 10 of this year the exclusive concession to land at the Azores. The company therefore expect to connect its lines from the Antilles to Europe by way of the Azores and Lisbon, and this, it is thought, will place the French company on terms of equality, or even of superiority, with the British companies in the Atlantic.

"There is Nothing New."—The interest excited by the experiments conducted by Mr. W. H. Preece with a view to electric communication between distant points without the intervention of wires, has not only drawn from Mr Willoughby S Smith an account of his father's experiments in the same line and of his own successful establishment of such communication between the shore and the Needles lighthouse in June last, but it has caused the people of Dundee to discover that both Mr. Smith and Mr. Preece have been in a way forestalled by one of their deceased townsmen, who experimented so far back as 30 or 40 years ago with success. This was Mr. James Bowman Lindsay, a man apparently of deep learning and considerable scientific attainments, but whose labours and accomplishments, curiously enough, have been allowed to fall completely out of general ken. Dr. Alexander Keiller, a pupil of Lindsay's, read a short account of his scientific experiments before the British Association in August last, and now another of his old pupils, Dr. Alex. Paterson, Bridge-of-Allan, comes forward to say that he can vouch that the so-called discovery that messages can be transmitted from island to island, or from ship to mainland, without wires is not new, for he well remembers that 60 years ago "the late learned scientist, James Lindsay, of Dundee, showed that he could transmit a message across the River Tay without wires." Lindsay's experiments and successes in this direction were well known at the time, but they seem to have been insufficiently recorded. In a biographical account of him, published at the time of his death, in the *Dundee Advertiser* of 30th June, 1862, it is distinctly claimed for him that he had discovered "the principles of the present system of electric telegraphy" by his own efforts, as early as, if not earlier than, Morse or Wheatstone. As a philologist, Mr. Lindsay was certainly entitled to high rank, as some of his published works show. There is no adequate biography of this remarkable Dundonian in existence, but as there are still a few survivors, such as Dr. Paterson, who were privileged to know him, the hope is expressed that some effort will be made to preserve the name of so accomplished a scientist from neglect by means of a worthy biography. It will be a gratifying circumstance for Dundee people, and a curious coincidence as well, should they be able to show that the discoverer of telegraphy and the inventor of the adhesive postage stamp were both respected burgesses of Dundee.

Large Gas Engines.—We are by no means certain that the position of the gas engine in the electrical industry has yet been correctly gauged. The advantages it presents for central station work are numerous. The necessity of keeping the load factor high forces the use of small units of power. These must be capable of being started at a few moments' notice, must occupy little space, and be cheap in working. Now, the gas engine has just these advantages, and the additional advantage of doing away with the boiler. The only objection is that the units hitherto have been too small—though makers are ready to supply large engines, their use is not sufficiently general to justify the adoption of 100 h.p. engines in central station work. The cost of fuel also is somewhat high, purified gas coming to much the same price for large engines as coal with boilers. Still, large gas engines are coming into use, and this fact will soon induce the station engineer to instal them for central supply. At Camden, New Jersey, a gas engine rated at 100 h.p. is in use, operated by a mixture of air and gasoline vapour. This provides a fuel not only invariable in quality but quite inexpensive. In quantities, gasoline costs 3d. a gallon; and as this engine is run by one gallon of 74-deg. gravity gasoline per horse-power for 10 hours, it will be seen that the cost of fuel (0·3d. per horse-power hour) is not great. The engine at present is only yielding 62 h.p. The cylinder is 16½in. diameter; stroke, 24in., speed, 150 revolutions per minute. The gasoline is drawn direct from a tank considerably lower than the engine, and its vapour is mingled with air without any special carburetting device. The governor limits the number of charges by an air gate passing over one of a pair of tubes. The air gate has two ports, and allows air to be drawn through either tube according to action of the governor. In one tube is a nozzle leading upward from a reservoir containing less than a pint of gasoline, and when the port is open above this tube the engine takes an explosive charge, which is ignited by incandescent tube. As the engine requires no fireman or skilled engineer, and uses cheap fuel which leaves no residue, it has great advantages over the steam engine. The credit of the invention of this engine (an illustration of which appears in the *Electrical World* of December 3) is due to Mr. Jas. A. Charter, who is well known in gas engine circles. We fancy the case should interest British engineers as an instance of the use of large gas engines. The engine was made by Caldwells, of Chicago, and is employed for driving a grain elevator. It is a compact machine, and its use for electric lighting seems likely to spread. With reference to this question of gas engine use, an outlet for ingenuity is also suggested by a recent article in the *Belfast Evening Telegraph* upon the discovery, by a Mr. Harris, of an easy way of making gas. This gentleman, again an American inventor, has a machine in which 10lb. of coal produces 700 cubic feet of gas, and by the addition of a couple of gallons of crude mineral oil this is raised to 100 cubic feet. Mr. Gallagher of Belfast, who introduces the method into the British Isles, vouches for the running of 110 16-c.p. lamps by means of a gas engine for 9d. for 10 hours, and the cost of the gas is given at 2½d. per 1,000 cubic feet. The paper to be read by Mr. Dowson before the Civil Engineers may also serve to turn attention further in the direction of the use of large gas engines.

THE RELATIVE MERITS OF HIGH AND LOW TENSION ELECTRIC DISTRIBUTION.*

BY WILLIAM BUCHANAN, B.SC., A.R.C.S., WHIT.SCH.

When a corporation or company find that they must keep pace with modern progress, and resolve on having an electricity-generating plant, the usual question which first confronts them is: Shall we adopt the high or low tension system? The object and scope of this communication is merely to induce a discussion of this question among the members. The use of high-tension direct current is very limited, owing to the necessary losses—mechanical and electrical—in the combined motor and dynamo-transformer. The only advantages which this system possesses over the alternating-current method are the readiness with which the energy can be stored, and the simplicity of its application to motors for power conversion. The question is thus practically reduced to the relative merits of high-tension alternating-current and low-tension direct-current methods, the latter including the three-wire and five-wire systems.

The chief merits of the high-tension alternating method of distributing electric energy are:

(a) The ease and efficiency of transforming the pressure either up or down. Transformers are now made and used which give out 97 per cent. of the energy supplied at full load, and 95 per cent. at half load, while the loss in running with open secondary is as low as 1½ per cent. of maximum load.

(b) The generating station can be placed in any suitable situation; for example, in proximity to a coal pit or depôt near a good water supply, or where ground is cheap and labour plentiful.

(c) The generating machines may either be worked at a high voltage or at a moderate voltage, the pressure being increased by means of step-up transformers; also the current can be sent along the trunk mains with a small percentage of loss, and without undue losses by heating.

(d) A considerable saving in the prime cost of all the mains.

(e) The advantages of running a large number of arc lamps coupled in series from the moderate-tension leads.

There might also be added as another merit of the high-tension alternating method its application to alternating motors; the advantage of this method for this purpose is obvious, and it has not received the amount of attention which it deserves. In engineering shops the throwing off of one large machine allows the driving engine to race, frequently causing a breakage of tools in those machines which are at work; in spinning factories also, the stopping of one frame often causes the breaking of the yarns on those frames which are running. It is almost impossible with any kind of mechanical governing to entirely check this racing of the engines. In cases like these there seems to be a large field for the use of alternating motors, since the motor must keep perfectly in synchronism with the machine generating the current. If the generator were supplying energy to a number of factories it would not feel the variation in load due to machines being turned off or on, so that it would run at a practically uniform speed, and therefore each motor would do the same.

The disadvantage connected with the use of ordinary alternating motors being that they are not self-starting. They must first be run up to the proper speed, and then switched into circuit at the proper moment. This is, however, overcome in the multiphase motor, with rotary field, designed by N. Tesla.

It is hardly necessary to point out the merits of the direct-current systems, not the least being the readiness with which dynamos may be coupled in parallel with each other, it being only necessary to run up a machine to the same voltage as those already running and then to switch it in. On the other hand, to put two alternators in parallel, besides getting the voltages to correspond, the dynamos must be got to nearly the same speed, if they have the same number of poles in the field magnets, and then switched in when the currents correspond in phase. Although this operation does not require any great skill, still it wants a certain amount of care, otherwise a large instantaneous current may be produced which will probably damage the machines.

At the present time the most important application of electric energy is the lighting of large towns and cities; for this purpose the great advantage of high-tension methods is in the relative sizes of the distributing mains compared to the low-tension systems. This advantage seems much more likely to increase than to diminish, seeing that the supply of high-conductivity copper is limited, while improved methods of insulating are being continually discovered. The simplicity of working is also much in favour of the alternating, compared with combinations of the two, three, and five-wire systems. In towns where there are already a large number of pipes—water, gas, hydraulic, drainage, etc.—the expense and difficulties of laying large culverts are very considerable. The usual method of distributing high-tension alternating current is by means of concentric cables. These consist essentially of an inner conductor or core of stranded copper surrounded by a certain amount—depending on the material used and the pressure worked at—of insulating material; over this is a layer of copper wire forming the outer conductor. The cable is protected by a further layer of insulation, over which is forced a covering of lead, so as to make the cable impervious to moisture. The whole is protected against mechanical faults by a sheathing of steel wires, which are wound above a covering of jute, so as to avoid injuring the lead. It is found, however, that the wire sheathing is not sufficient protection against blows from a sharp pick, nor does it offer much resistance to the sharp wedges driven by sledge-hammers to break up the concrete pavements. The best mechanical protection seems to be got by encasing the cables in cast-iron pipes, the pipes being first laid down and lead-jointed, and then the cable is drawn through in lengths of about 200 yards.

There are a large number of methods in use for joining lengths of concentric mains, or connecting service leads, the most common, perhaps, being to connect the inner conductor by splicing and soldering, then to wind over it a sufficient thickness of insulating tape; over this is laid a number of strips of sheet copper, to which are attached the outer conducting wires by thin copper binding wire; more tape wound over this completes the joint. In lead-covered cables these joints are protected by soldering a lead covering over them; in others, by surrounding the joints by cast-iron boxes charged with oil or insulating compound. Whenever possible, these joints should be placed inside street boxes so as to be readily accessible in case of faults occurring, or when it is required to recharge the boxes with oil or compound, it being found that the oil tends to leak from the box along the insulation of the cable.

The methods of laying low-tension mains are so well known that it will be sufficient merely to mention those of two large companies—namely, "The Westminster" and "The Kensington and Knightsbridge."

The Westminster mostly adopts the plan of fixing the conductors on insulators laid in concrete conduits, then cementing on a concrete cover. The chief merit of this system is that the culvert prevents moisture penetrating to the insulators, and also forms a mechanical protection for the conductors. On the other hand, it has the disadvantage of taking up a wide strip of ground, and breaking up in order to put in joints or examine for faults is rather costly.

The method of the Knightsbridge Company is to stretch bare conductors over porcelain insulators about 50 yards apart, the whole being placed in an open culvert. This method has the advantage of being fairly cheap, and also that the mains are readily accessible for jointing or repairing; its disadvantages lie in the large amount of ground area used, leakage through moist insulators, and corrosion of the copper by acids arising from foul air in the conduits.

One disadvantage which seems to be inherent in the use of concentric distributing mains is the difficulty of locating a fault on a branch circuit, that difficulty being in the fact that a current flowing uniformly along a con-

* Paper read before the Physical Society of Glasgow University, December 16, 1892.

ductor of circular section has the same effect on external bodies as it would have if concentrated along the axis of the conductor.

With the low-tension system it is found to be rather difficult to keep the voltage anything like uniform over a circuit, the fall of potential being different at different places, and often at different times; this necessitates the employment of feeders from the station, and of pilot wires to enable the voltage at distant places to be known.

With the method mostly in use in high-tension distribution, the current is transformed at a number of stations to 2,000 or 2,500 volts, and distributed at this tension to consumers' premises, where it is transformed to 100 volts. There is practically no fall of potential in distributing over a distance of two or three miles at 2,500 volts, and even the small amount there is may be neutralised by cutting out one or two turns of the primary circuit on the transformer. It must also be kept in mind that the fall of potential in an alternating circuit cannot be expressed by so simple a formula as that used for direct currents, but by one which takes into account the capacity of the concentric main, the amount of induction in the circuit, the pulsation period of the current, and the transforming ratio of the converters, as well as the current and ohmic resistance. If the alternations are of high frequency, and the conductor has a capacity large in comparison with its ohmic resistance, the pressure may be even greater at the far end of a circuit than at the generating end.

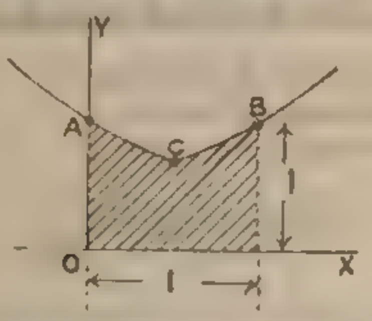
It is shown in Dr. Fleming's book on "The Alternate Current Transformer," vol. ii., p. 170, that if L, R, and V_1 are the inductance, resistance, and potential respectively at the generating end of a circuit — such as a trunk main of concentric cable — and l, r, and V_2 the like quantities for the distributing end, when p is the pulsation of the current, and C the capacity of the cable, that

$$\frac{V_1}{V_2} = \sqrt{\left\{(1 - CLp^2)^2 + C^2R^2p^2 + \frac{(1 - 2CLp^2)(R^2 + p^2L^2) + 2Llp^2 + 2Rr}{r^2 + p^2l^2}\right\}}$$

If circuit beyond condenser is open, then $r^2 + p^2l^2 = \infty$, and the above equation reduces to

$$\frac{V_1}{V_2} = \sqrt{\{(1 - CLp^2)^2 + C^2R^2p^2\}}.$$

The effect due to the capacity of the condenser is very well shown by considering the particular case in which $R = Lp$. Writing Y instead of $\frac{V_1}{V_2}$, and x for CLp^2, the above equation reduces to the hyperbola $Y^2 = (1 - x)^2 + x^2$. Y is $= 1$ when $x = 0$ or $x = 1$, and Y is a minimum when $x = \frac{1}{2}$.



This shows that in the particular case chosen V_1 is equal to V_2 when CLp^2 is equal to zero or unity, while for any value between zero and unity V_2 is greater than V_1, and for values of CLp^2 greater than unity V_1 is greater than V_2.

To enable us to arrive at some definite results, I have worked out approximate values for the lighting of an area of one square mile, by what seems the most suitable distribution in each case, for the high-tension and the low-tension systems.

The method of high-tension distribution adopted is that of using a number of sub-transformer stations from which the low-tension mains are fed at a number of points. The chief loss in the transformer system being due to the running at light load during the day and early morning, it becomes almost a necessity to use some means of minimising this loss. A number of methods of doing this have been tried or suggested. Mr. Ferranti has designed an automatic switch, which cuts out a transformer when the current through the secondary falls below a certain amount. In the sub-station method, a number of transformers being connected in parallel, we may have some cut out and keep those remaining working nearly at full load, and therefore at a high efficiency.

In the case we have chosen as an illustration, it is supposed that the square mile is divided into squares of 220 yards frontage, and that the density of lighting is uniform at the rate of 500 8-candle, or 30-watt, lamps per square. The total number of lights is thus 32,000, while the power required is 960 kilowatts. We will further suppose that the annual load factor is 30, load factor being defined as the percentage which the total work done in a certain time is of what it would be if the load was continuously at its highest value during that time. In the curves of Figs. 1

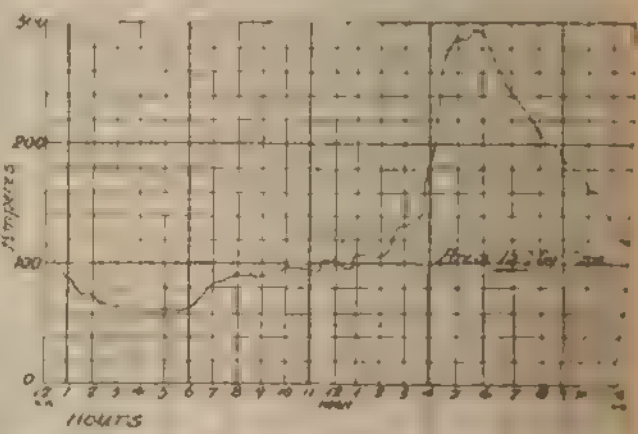


Fig. 1.—Load Curve for 24 hours. Load factor = 42 per cent.

and 2 the daily load factor is the percentage which the area enclosed between the curve and the zero line is of the area got by taking the product of the length of the base line and the maximum ordinate of the curve.

In the high-tension method we will suppose the current to be generated at 8,000 volts at a distance of four miles from the centre of the area to be lit, and transformed to 2,000 volts in the distributing station, being finally reduced to 100 volts at the sub-stations. The dimensions of the cables and mains are calculated by means of Lord Kelvin's

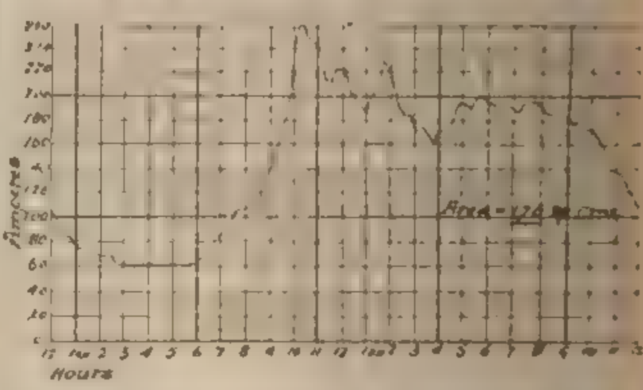

Fig. 2.—Load Curve for 24 hours. Load factor = 57 per cent.

rule: The number of watts lost per annum multiplied by the cost of generating one watt equals the interest on the cost of the mains. It seems, however, that this rule ought to be slightly modified to take account of the fact that the cost of upkeep of a given main will be more than that of a better or more costly one. Thus, a high-tension main requires more insulation relatively than a similar low-tension one, and is thus more costly, so that a high current density would be given by using the rule, but the heating effect of the current causes deterioration of the insulating material with correspondingly increased cost of upkeep, so that it very probably would be found more efficient to use a lower current density by laying a slightly larger main.

A method of arriving at the dimensions of the cables is as follows:

Let p = cost per mile of cable
,, q = cost per mile for laying.
,, A = cross-sectional area of conductor in inches.
,, C = current in amperes.
,, R = resistance per mile in ohms.

Then $(FC)^2 R \times 24 \times 365$ is the watt-hours lost per annum, where F is the annual load factor and C the maximum current which the cable is supposed to carry. Also $RA = 0{\cdot}044$ for ordinary copper, and $p = £\,(3{,}000\,A + 300)$, from practice, for concentric cables. Allowing $7\frac{1}{2}$ per cent. as the interest on cost of mains, then $£\,(225\,A + 22{\cdot}5)$ is interest on cost per mile; but with F = 30 per cent., and taking cost of generating one B.T.U. as 3d., we have

$$C^2 = \frac{20 \times 4{,}000 \times 100 \times 22{\cdot}5\,(10\,A^2 + A)}{9 \times 0{\cdot}044 \times 24 \times 365}$$

or, $$C = 228\,\sqrt{(10\,A^2 + A)}.$$

For $A = 1''$ we get $C = 228\,\sqrt{11} = 752$ amperes per square inch
" $A = \frac{1}{2}''$ " $C = 395$ $= 790$ " "
" $A = \frac{1}{4}''$ " $C = 213$ $= 852$ " "
" $A = \frac{1}{10}''$ " $C = 102$ $= 1{,}020$ " "

But we cannot allow a current density of more than 1,000 amperes per square inch for alternating current, so

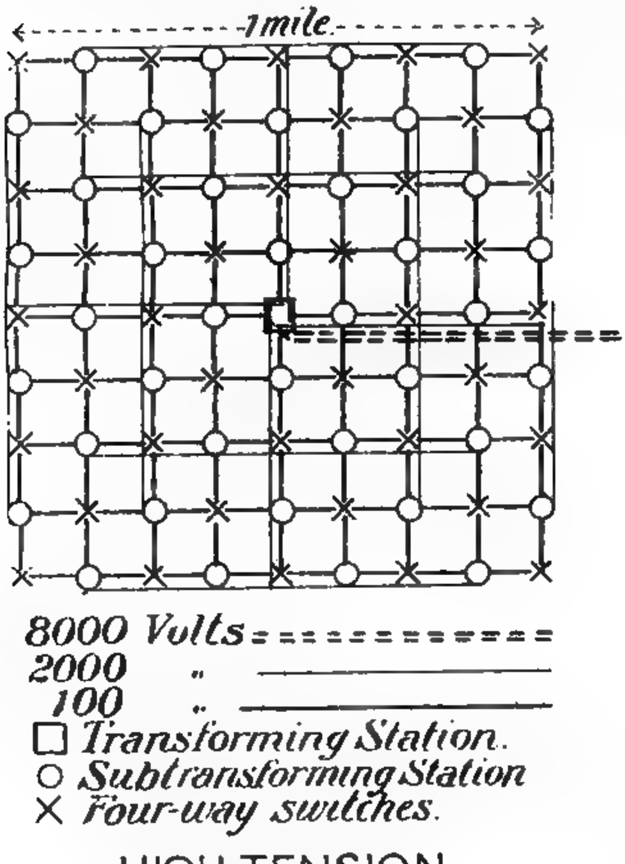

Fig. 3.

for sizes below $\frac{1}{8}$in. section we must calculate the size of conductor by allowing this amount. This apparent defect in the rule arises from the fact that it costs almost as much to lay a small cable as a large one.

The dimensions of the low-tension mains may be calculated by allowing a maximum current density of 1,000 amperes per square inch for the two outside wires, and making the intermediate wires in the three and five wire systems half the sectional area of these.

I have not taken into account the frequency of alternation in calculating the size of conductors, as those for concentric mains are usually made of a number of separate wires, so that if the frequency is about 80 per second the increase of resistance is not large.

The method of dividing up the area to be lit is purely arbitrary, and must be considered quite hypothetical, but still as a means of comparison it will be sufficiently simple and useful. The area chosen and the density of distribution are rather favourable for a low-tension system. It will be observed, from the diagram of Fig. 3, that any fault occurring on the high-tension system affects only a straight length of 220 yards, and by means of a wire laid along the street from end to end, the position of the fault could readily and accurately be found by a loop test. If a transformer failed, the area could be lit from the others by means of the street switches shown in the diagram.

I will now give some details relating to the mains. First considering the high-tension system, we require at least two trunk mains, each capable of carrying all the current. Allowing a gross efficiency of 80 per cent., the trunk mains must be designed to carry $(960{,}000 \div 8{,}000) \div 0{\cdot}8 = 150$ amperes; so we may allow $\frac{1}{4}$ square inch section. The cost of concentric cable $\frac{1}{4}$in. section is about £800 per mile. The two mains can be laid at a cost of about £400 per mile run. Thus the total cost of trunk mains is £8,000. The resistance of this section for alternating currents is $\frac{1}{5}$ ohm per mile, and therefore the total resistance with the two mains in parallel is $\frac{4}{5}$ ohm.

As it may often be necessary to use only one trunk main, it will be more correct to use a load factor of 40 per cent. in this case. If then C_A is the average current strength, and C_m the maximum current, $C_A = \frac{4}{10}\,C_m$, and therefore $(C_A)^2 = \frac{4}{25}\,(C_m)^2$, so that the average rate of loss is $\frac{4}{25}\,(C_m)^2\,R$, where R is the total resistance of the circuit considered. For the trunk mains the loss is therefore at the rate of 2,880 watts, or, taking the cost of generating as 3d. per B.T.U., the loss is £316 per annum. With one

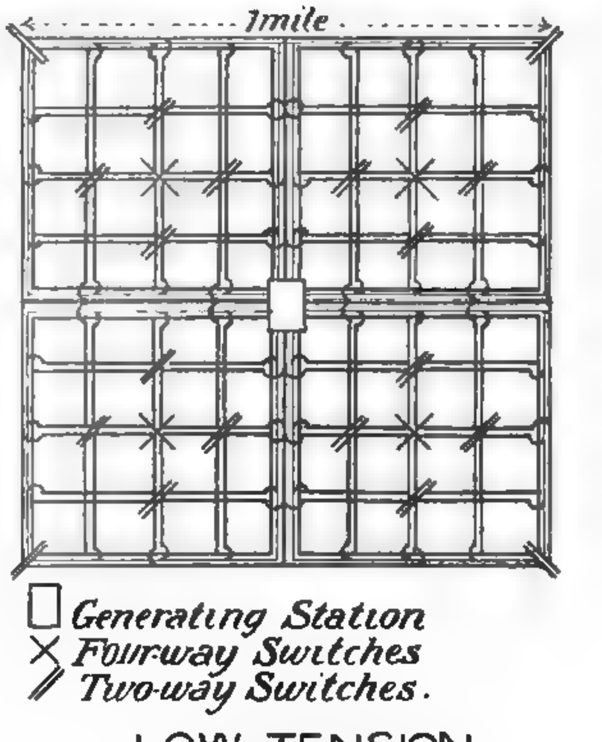

Fig. 4.

main in circuit only, the fall in potential due to ohmic resistance at full load is $150 \times 0{\cdot}8 = 120$ volts or $1\frac{1}{2}$ per cent. at 8,000 volts. With both mains in circuit the capacity effect will most probably annul the drop due to ohmic resistance. The following table gives the sizes of mains required in the various sections, with their cost and the loss in watts.

Details of Distributing Mains.—High-Tension System.

—	Length Miles.	Maximum current. Amperes.	Gauge B.W.	Resistance per mile. Ohms.	Cost per mile. £.	Total cost. £.	C^2R. Average
2,000 volts.	[illegible]	$7\frac{1}{2}$	7/19	5·0	80	160	102
	3	15	7/16	2·0	120	360	243

			Totals..........			7,955	4,257

It must be observed that the lengths given are for

concentric cable, so that in calculating the resistance twice the length must be taken, also in the low-tension leads, since the density of lighting is supposed to be uniform, the actual average resistance is only one half the total resistance of any circuit. The losses tabulated under $C^2 R$ are reckoned on the assumption of an annual load factor of 30 per cent. The cost of laying the mains may be taken as £200 per mile for the low-tension leads, and £300 per mile where both high-tension and low tension leads are laid. We thus have eight miles at £300 per mile, and 10 miles at £200 per mile, or a total of £4,400.

The total cost of the distributing mains is therefore £12,355; the loss due to heating being at the rate of 4,257 watts, and amounts to £480 per annum. Also £480 is 4 per cent. of £12,355; but £480 is 6 per cent. of £7,955—*i.e.*, of the cost of the mains. The following table gives the probable costs of the different parts of the whole system.

Cost of Alternate-Current Plant.

Engines, 5 × 500 h.p. at £4 per h.p. ...	£10,000	
1 × 300 h.p. at £5 „	1,500

		17,700
		£77,000

Allowing £3,000 for plans and supervision, the total cost will be about £80,000.

Considering next the low-tension system of distribution, a reference to the diagrams, Figs. 3 and 4, will show that there are two miles of five-wire, four miles of three wire, and 12 miles of two-wire leads. Remembering that five wires are equivalent to 3½ of the outer conductors, and three wires to 2½ the outer, we form the following:

Details of Distributing Mains.—Low-Tension System.

—	Length Miles.	Maximum current Amperes.	Gauge B.W.	Resistance per mile Ohms.	Cost per mile £	Total cost £	$C^2 R$ Average

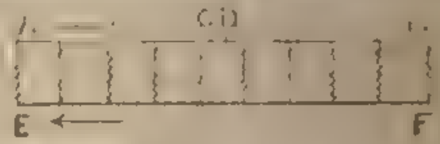
			Totals ...			20,210	15,964

To calculate the loss by heating in a circuit of uniform section, in which the current varies uniformly from zero to its maximum value C, let A B = l be one conductor and E F the return; also let r be the resistance per unit length let C_x denote the value of the current at C, and let C D = dx. We have, therefore, $C_x = \frac{l - x}{l} C$, and heating is at the rate of $\int_0^l C_x^2 r\, dx = C^2 r \int_0^l \frac{(l-x)^2}{l^2} dx$ $= \frac{1}{3} r l C^2 = \frac{1}{3} R C^2$, where R is total resistance of one lead. The loss in the general case in which C_1 and C_2 are the currents at A and B respectively is $\frac{1}{3} R (C_1^2 + 2 C_1 C_2 + \ldots$



The cost of laying will be about £350 per mile for double leads, £400 for three-wire system, and £500 for five-wire system. The cost is, therefore, 12 × 350 = £4,200 for double leads, 4 × 400 = £1,600 for three-wire leads, and 2 × 500 = £1,000 for the five-wire leads, or a total of £6,800.

The total cost of the distributing mains is thus £27,010. The loss by heating is at the rate of 15,964 watts, or at 3d. per unit is £1,760 per annum. Also £1,760 is 6½ per cent. of £27,010.

This is a higher percentage than allowed in the high-tension system, the reasons being that more heating is permissible with low-tension than with concentric high-tension leads, as the risk of damaging the insulation is greater in the latter case; it is also expedient to reduce the first cost of the low-tension mains as much as possible, in order to compete successfully with high-tension systems.

Cost of Direct Current Plant.

Total		[illegible]

Briefly comparing the relative efficiencies of the two systems, we have—

(*a*) *Alternating System.*—Mechanical loss in 500 h.p. engines, 10 per cent.; mechanical loss in dynamos, 2 per cent., electrical losses in dynamos, 4 per cent., loss in trunk mains, 1½ per cent.; loss in station transformers, 3 per cent. (these will always be working full power), loss in 2,000 volt mains, 1 per cent.; loss in sub-station transformers, 8 per cent., and loss in 100 volt mains, 1½ per cent., or a total loss of 30 per cent.—the average efficiency of the system being thus 70 per cent., and the average power required; therefore, $\frac{960}{0.746} \times \frac{100}{70} \times \frac{3}{10}$, or 550 h.p.

The fall of potential at the most extreme parts of the circuit at full load is made up of a fall of 1½ per cent. in the trunk mains, of 1½ per cent. in the 2,000 volt mains, and 2½ per cent. in the 100 volt leads, or a total of 5 per cent., this being compensated, however, by the increase of inductance of the transformers at high loads.

Since all the boiler power is only used for a small portion of the 24 hours' run, the alternate heating and loss by cooling and in cleaning fires make it improbable that a higher efficiency than 6lb. of coal per indicated horse power per hour can be got, there will thus be used 13,000 tons of coal per

annum, which, taken at 12s. per ton, costs £7,800. Allowing £2,200 for water, oil, stores, and steam for auxiliary engines, we have a total of £10,000 per annum. The wages for running the plant will amount to about the same amount—*i.e.*, £10,000. Allowing 10 per cent. for upkeep of engines, dynamos, boilers, and mains, a further £6,000 is required, and 20 per cent. on transformers and switches is £2,000, while 5 per cent. on buildings is £300. The total expense per annum is thus £28,300. If we further allow £5,700 for directors' fees, and write off £10,000 for depreciation of plant, the total outlay per annum is £44,000. The total number of units sent to the lamps is 2,470,000 per annum, and allowing 90 per cent. of this to be paid for at 6d. per unit, the annual income is £55,600. This allows a dividend of 14 per cent. on the £80,000 first cost.

(*b*) *Direct-Current System*.—Mechanical loss in 350-h.p. engines, 12 per cent.; mechanical loss in dynamos, 3 per cent.; electrical losses in dynamos, 5 per cent.; loss in five-wire leads, 2½ per cent.; loss in three-wire leads, 1½ per cent.; loss in double leads, 2 per cent.; or a total loss of 26 per cent.—the average efficiency of the system being thus, 74 per cent.; the average power required being therefore 520 h.p. through 24 hours per day. The fall in potential at the extreme parts of the circuit on full load is made up of a fall of 5 per cent. in the 400-volt leads, or 5½ per cent. in the 200-volt leads, and of 6½ per cent. in the 100-volt leads, making a total of 17 volts in 100. A large portion of this drop would be compensated by connecting the mains into a number of loops, but this method has the disadvantage that if a fault occurs, all the circuits looped with the faulty one have their lights out. It would be better to run one or two extra leads as feeders to the extreme parts of the circuit.

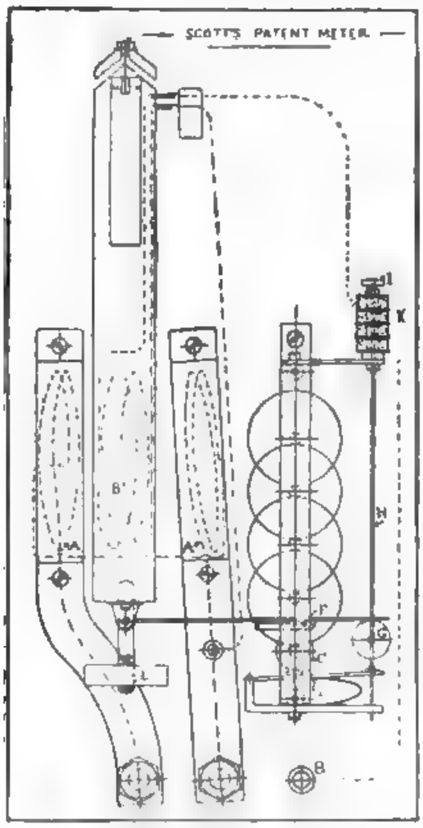
If engines and dynamos are worked only 12 hours per day, the batteries running the load from 2 a.m. till 2 p.m. the average power required will be 1,040 h.p., and we might have an efficiency of 5lb. coal per indicated horse-power per hour, thus using 11,000 tons of coal per annum, which, taken at 16s. per ton—the price in centre of area—amounts to £8,800. Allowing £2,200, as before, for water, oil, stores, etc., we have a total of £11,000 per annum. The wages for running the plant will be perhaps £1,000 less than in the former case, or, say, £9,000 per annum. Allowing 10 per cent. for upkeep of engines, etc., amounts to £7,000 per annum, while 20 per cent. on batteries and switches is £1,000, and £5 per cent. on buildings is £350; if, further, we allow £5,650 for directors' fees and write off £8,000 for depreciation of plant, the total outlay per annum is £42,000. Supposing the income £55,600, as in the former case, this allows a dividend of 15 per cent. on the £90,000 first cost.

I hope that the appearance of 14 per cent. and 15 per cent. dividends will not induce members into a wholesale purchase of electric lighting shares, for they must strictly observe that the conditions assumed are merely relative and not actual ones. I have assumed a favourable distribution; in practice, it is sometimes required to run half a mile of cable for 200 or 300 lights, and of sufficient size to be able to carry 10 times as many. The main reason why electric lighting companies are as yet unable to produce high dividends is that they require to put down buildings, plant, and mains of much larger capacity than is required for a number of years. If a corporation took up lighting an area, wired every street, and put a service into each house on the same principle as gas is supplied, then a system could be designed suitable to the requirements of the area, and with a fair density of lighting the cost would compare favourably with that of gas. As it would be inconvenient for me to be present at the discussion, I have entered into a more detailed examination of some parts than otherwise I might have done.

SCOTT'S ELECTRICITY METER TIMED FROM A CENTRAL POSITION.

The diagram shows a diagrammatic view of Scott's patent electricity meter, made by Messrs. Laurence, Scott, and Co., Limited, Norwich. As originally designed, a self-winding clock was included in each meter, which made it a somewhat complicated and expensive instrument, as the workmanship in an automatic apparatus of this kind must be very good. By doing away with the clock in each meter, and making one clockwork apparatus in a central position do for a whole lot of meters, a very simple and practical system is made, which, notwithstanding that a special meter wire has to be laid with the supply mains, works out cheaper in most cases than the ordinary system of meters.

The great advantage of the system, however, is that it enables the rates of charge for supply to be made different at different times of the day. This will be referred to further on. The meter itself is very simple, as will be seen from the diagram, which shows all the working parts. A A are the fixed series coils of strip copper, through which the current to lamps flows. B represents the movable shunt coil, whose resistance is about 1,500 ohms, with its terminal, B[1], for connecting to the special meter wire. C is the friction roller geared to indicating train. E is a brake to prevent C from being turned round otherwise than by the proper action of the meter. F is the friction



pad which, when lowered on to C, will communicate to that wheel any movement of the suspended coil, B. G is the roller on vertical carrier, H, which is lowered when the armature, I, of little magnet, K, is attracted. L is the adjusting weight.

The meter wires in connection with the shunt terminal, B[1], are periodically connected up to the lighting mains by the clockwork at the central position, or by a relay operated therefrom, so that a shunt current is periodically sent through the suspended coil, B, and through the little magnet coil, K, pulling the pad, F, into gear with the friction roller, C, and thus communicating the forward movement or "deflection" of the suspended coil, B, to the roller, C, this movement being exactly proportional to the current flowing in A A when the difference of potential at the terminals of the shunt is constant. When this shunt current is broken by the central clockwork apparatus the friction pad is lifted off the roller, C, before B commences its backward movement, so that the indicating train is only moved in one direction, and the various forward movements of B are integrated on it. The meter works on the most accurate principle that is known, and very careful experiments have been made to find out whether there can be any error from the way in which the principle is applied. It has been found that these meters, made as shown in the

diagram, have an accurate range of over one hundredfold, and this could be very much exceeded if there were any necessity for it.

The meter is generally arranged to give accurate readings in Board of Trade units, when the shunt circuit is completed every 90 seconds. The shunt current remains on for about 12 seconds. The central clockwork is arranged to make contacts one after the other with six separate circuits of meter wires, and as the resistance of the shunt circuit of each meter is about 1,500 ohms, there can be 45 meters on each of the six circuits, or 270 meters altogether, worked with a total shunt current of three amperes, so that $^7/_{20}$ or $^1/_{18}$ cable is amply large for the main meter wires, one branch wire of $^1/_{22}$ being taken from one of these meter mains to each meter in the customer's premises. For long distances and large numbers of meters a relay can easily be arranged in a junction-box, which will connect the next length of meter wire to the mains synchronously with the first length. The simplicity and consequent cheapness of this meter will more than balance the cost of the special meter wires in cases where the kind of mains employed permits of these being used.

If instead of sending a shunt current into the meter once every 90 seconds, this interval is increased to 180 seconds, the meters will indicate only half the current used. The clockwork at the central position can be arranged so that the alteration can be easily effected, and if the alteration from a 180 second period to a 90 second period is made, say, an hour before sunset by the almanac all the year round, and back again at some fixed time during the evening, it is evident that during the whole of the ordinary working hours in the summer, and the greater part of them during the winter, the current will be supplied at half-price, making the cost of power from electric motors compare favourably with that from gas engines. During these hours this will pay the supply companies, as, if they were not supplying this current, their plant would be almost standing idle.

It may be objected that this "power" load will overlap the "lighting" load, but during this time the current will be paid for at the lighting rate, and there will be many instances where consumers will arrange so that they do not use power at those hours in order to avoid paying the higher rate. It will also encourage the use of electric power during the summer time only, as there are many manufacturers who have steam power that they would gladly stop during the summer months, but which they prefer to run in the winter, as they utilise the waste heat for warming their premises. The shunt currents can easily be made to record themselves on suitably arranged paper marked with the time of day, so that the timing can be checked at any time.

FIELD MAGNETS.

BY GISBERT KAPP, M.I.C.E.

[By the permission of the author and the publisher we are enabled to give the following extract from Mr. Kapp's forthcoming treatise on "Dynamos, Alternators, and Transformers." We may add that the book will probably be ready early in January.—ED. *E. E.*]

The magnetic field within which the armature revolves may be produced either by the use of permanent steel magnets or electromagnets. The former are not so effective as the latter, and are only used in exceptional cases, notably in the older forms of machines for lighthouses and in very small dynamos, where simplicity of construction is of more importance than small weight—such as mine exploders, medical machines, signalling apparatus, and machines for laboratory work. There is, besides simplicity, a further reason for using permanent steel magnets in preference to electromagnets for very small machines, and this is that the energy required for exciting the magnets becomes inordinately great when the size of the machine is reduced beyond a certain limit, as will be shown later on. Machines with permanent steel magnets are known under the name of "magneto machines," whilst the term "dynamos" is more particularly applied to machines in which the field is produced by electromagnets. Since magneto machines have only a very limited sphere of application, we pass at once to the consideration of the field magnets of dynamos. The number of types of field magnets which have been used or proposed for dynamos is exceedingly great, but the difference between many of these is more apparent than real. It will therefore be best not to attempt to give a complete list of all the various designs of magnets, but rather select a few representative types for purposes of comparison. In any electromagnet we have to distinguish between two circuits, the electric and the magnetic circuit. These two must be interlinked, so that the current through the electric circuit may produce a flux of lines of force through the magnetic circuit, and the difference in type of dynamo field magnets is due to the more or less suitable arrangement of these two circuits.

Two-Pole Fields.—The most simple arrangement is that shown in Fig. 23. Here we have a coil of wire, W, interlaced with a ring of iron, R, cut open at G. If the gap G be made of cylindrical or tunnel-like shape, it may receive a cylindrical armature, and thus Fig. 23 may be considered as representing the field magnet of a dynamo machine, but on the whole not a good arrangement. In the first place, the length of wire in the coil is unnecessarily large, and this can be reduced by laying the wire more closely round the iron ring, and spreading it over a great portion of it. In the next place, the curved form of magnet is bad from a practical point of view, partly because a forging of this kind is difficult to produce and to

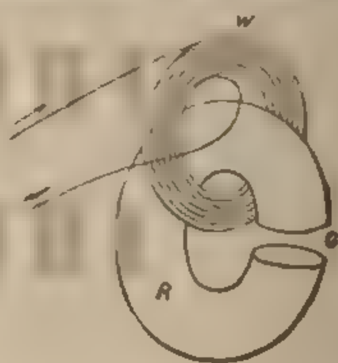


FIG. 23.

fix in the frame of the machine, and partly because it cannot be wound in the lathe. It has been shown in Chapter V. that neither the shape of the core nor the disposition of the exciting wire have a direct influence on the magnetic flux produced by a given exciting power, and we are therefore free to alter the shape and arrangement of the magnetic and electric circuit in such manner as may be convenient. Instead of a bank of wire we may thus use a cylindrical coil wound on a former in a lathe, and instead of the curved iron core we may use a core consisting of straight pieces, which are more easily forged, machined, and put together. We may also make the pole pieces detachable from the magnet core proper if by doing so we obtain some advantage as regards manufacture, but in this case we must take care to fit the different parts of the magnetic circuit properly together so as not to impede the flow of lines when it passes from one part to the next. In this way we arrive at something like the design shown in Fig. 57a. M is a straight cylindrical magnet core of wrought iron shouldered into the cast iron pole pieces, P P, and C is the exciting coil.

It will be seen at a glance that this arrangement is electrically and magnetically equivalent to that shown in Fig. 23, but mechanically it is a great improvement. The design is simple and substantial, all the machining can be done on a lathe or boring machine, and the coil may be wound on a separate frame and slipped on when the machine is put together. This winding of magnet coils separately is important, not only because of facility for repairs, but chiefly because it is possible to keep the electrical and the mechanical part of the work in distinct departments. If the coil is wound directly upon the magnet core a much greater weight has to be handled and there is a risk of the insulation being injured by metal

chips or filings, which are necessarily present in a shop where machine tools are at work and fitting is going on For this reason it is best to do the winding and other electrical work in a separate shop.

The design of magnet shown in Fig. 57a, although, as was already said, perfectly practical, is still capable of improvement in two ways. In the first place, the magnet being on one side of the armature, the field is slightly unsymmetrical, and in the next place the arrangement is very heavy. Both of these defects can be remedied by duplicating the magnetic circuit, as shown in Fig. 57b We require now two exciting coils and more wire, but we obtain, on the whole, a lighter machine, and one in which the field is perfectly symmetrical.

The field magnet, Fig 57a, has another defect, inasmuch as the coil is short, and has therefore only a small external surface through which the heat generated by the

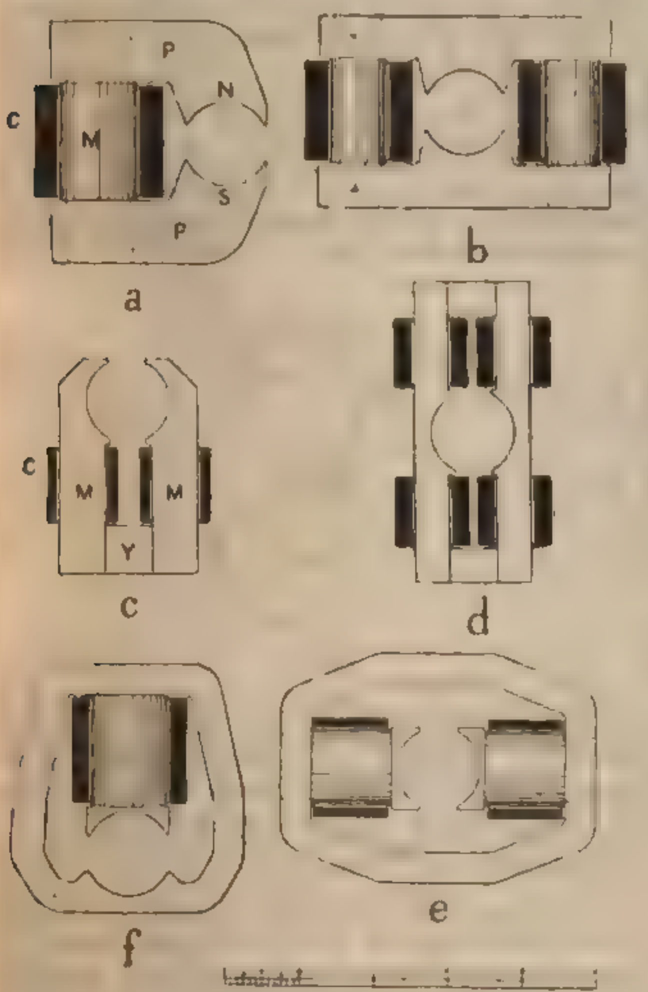

Fig. 57.

passage of the current can escape. Practical experience has shown that for every watt absorbed by the resistance of the coil there must be provided a certain area of cooling surface, if the temperature of the coil is to be kept down at a safe limit. Authorities differ as to the exact number of square inches of cooling surface required per watt of energy dissipated, and it is obviously impossible to lay down a hard-and-fast rule, as the disposition of the machine, with regard to the fanning action of the armature and the locality where the machine is used, must necessarily influence the rate at which the coil can dissipate heat, but, generally speaking, the cooling surface should not be less than one square inch and need not be more than four square inches per watt. To prevent the coil, in Fig. 57a, from becoming too hot, we must, therefore, either increase its external surface by making it longer and shallower, or we must put more copper into it. The first expedient is of doubtful value, as it leads to a much heavier field, and the second is expensive. We can, however, alter the design altogether so as to obtain enough cooling surface without increasing the weight of the field. We need only treat the part marked M as the yoke, and put coils on the two limbs marked P P in Fig. 57a In this way we obtain the design shown in Fig. 57c, which is a very favourite type. By putting two exciting coils on the magnet limbs, M M, we have not only increased the cooling surface, but have also materially decreased the whole weight of the machine

This design is known as the "overtype" field. By reversing it—that is, putting the armature below, and the yoke, Y, at the top we get the "undertype" field, which is also much in use, and is specially adapted for direct-driven machines, where it is important to get the spindle low down to correspond with the position of the engine shaft. In this case the machine is supported from its pole pieces by brackets or packing pieces of non-magnetic material. In the overtype these pieces are not required, and the yoke may be either bolted direct to the bed plate or may be cast in one piece with it.

This type of field, although lighter than the previously described types, is still rather heavy if the diameter of the armature is large in comparison with its length. If such an armature must be employed, and if it is important to save weight, we may duplicate the field, and thus we obtain the type shown in Fig 57d. This contains less iron than the overtype field, but more copper, and, although, on the whole, it is considerably lighter, it is also more expensive.

Figs 57e and 57f shows fields of the "iron-clad" type. Their characteristic feature is that the yokes surround the magnets completely. There is consequently no stray magnetic field. Fig. 57e is very heavy, but requires little wire, whilst Fig. 57f is not quite so heavy, but requires more wire.

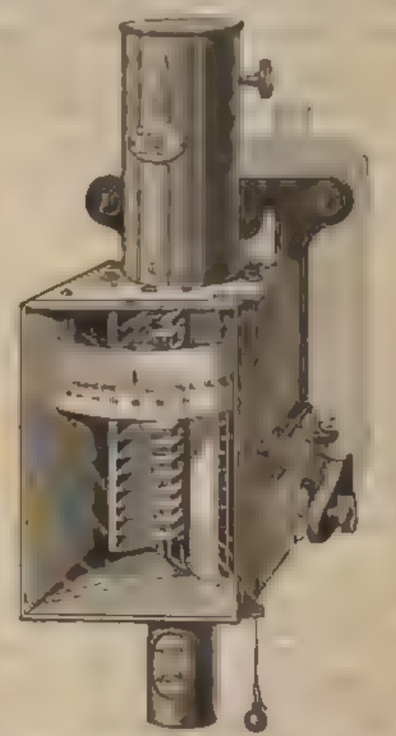
To give at a glance an approximate idea of the amount of copper required in each type of field, the space occupied by the coils is shown in black. The fields are all designed to take the same size of armature—namely, a drum 12in. diameter by 15in. long.

(To be continued.)

TRADE NOTES AND NOVELTIES.

LORD KELVIN'S NEW FORM OF ELECTROSTATIC VOLTMETER FOR LOW VOLTAGES.

The arrangement of the vanes and cells of this instrument are much the same as those of the multicellular voltmeter



already described in these columns. The instrument is specially designed for use on switchboards, and has a vertical scale instead of the old plan of reading with a mirror It is rendered practically dead beat in its action by a small horizontal disc, which turns in an oil dashpot below the case. The zero adjustment has been much improved by the addition of a torsion head and micrometer screw.

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free. Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. IX. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

HIGH AND LOW PRESSURE.

It is easy to foretell the gist of a report when the reporter's name is given. Thus, Prof. Ayrton's report to Cheltenham could easily have been written by a plagiarist possessing fair ability and a fund of good common sense. The report, as will be seen, proceeds upon general lines, and except on one or two points is such as can be generally subscribed to by everybody. We do not think his estimated calculation of the difference of the first cost of plant, when considering transforming by accumulators, motor-dynamos, and alternate-current dynamos, is correct. Further, we do not think the tabulated statement as it stands is a fair one to put before users in order to influence their opinion one way or another. Ten thousand times too much is made of prime cost, and ten thousand times too little of maintenance. Again, prime cost is not restricted to accumulators or motor-dynamos, but must be considered of the whole system, and it may be that by using some one of accumulators, or motor-dynamos, or alternate-current transformers the prime cost of other parts of the apparatus may be considerably reduced. Probably Mr. Crompton would say, and try to prove, that the prime cost of the whole apparatus was little, if any, greater with accumulators than with other kinds of transformers. If figures of the kind mentioned are to be given, they should be complete. The second point we should like to express an opinion upon is that relating to 100 or 110 volt lamps, and the saving of cross-section in mains by using the latter. Why stop at 110 volts? Is there now to be uniformity of practice? Recently it has seemed as if we were settling down to a uniform use of 100 volts pressure. Now it is suggested Cheltenham should have 110 volts; to-morrow it may be suggested that some other town have 120, and so on. Makers of apparatus desire to have stock patterns, and by making to stock supplying orders straight off the reel; but if there is no uniformity such a state of things is impossible. It will be seen that we have nothing to say against 110 volts, or any other particular pressure, provided everybody adopts it. The lampmakers might suggest that the greater the uniformity of lamps the greater the probability of getting the best possible lamps. There will still be plenty of room left for the services of the consulting engineer even should the uniform pressure at the house terminals be 100 volts. The great feature of the Cheltenham scheme is that the design starts with a definite view to use the waste heat of destructors, and if carried out will be the first systematic attempt to do this for electric lighting purposes on a large scale.

Mr. Buchanan's paper to the Physical Society of Glasgow, given elsewhere in our columns, comes as a welcome contribution on the subject. No doubt objections will be found to some of the figures, but as with Prof. Ayrton's report, we shall refer to one point—the assumption as to the percentage of units paid for of those sent out. Far too little authentic information is forthcoming on this, but what little there is shows Mr. Buchanan's percentage to be rather too favourable. Gradually we are

getting at what may be termed the average cost of generation per unit, an exceedingly important subject, especially to engineers, but, as with the distribution of gas, the number of units generated and the number of units paid for are separated by a tolerably wide gulf. How wide or how narrow is what the shareholders want to learn.

THE ELECTRIC CONSTRUCTION CORPORATION'S NEW ISSUE.

The ordinary general meeting of the Electric Construction Corporation is held to-day, and no doubt much interest will be exhibited at the meeting, but as we necessarily have to write before the meeting the results cannot be given in this issue. However, two very tangible documents are before us, either of which is worthy of a sermon—the balance-sheet of the corporation, and the prospectus of a new issue of £100,000 second mortgage debentures. Long ago we expressed our opinions as to the finances of the corporation, and those criticisms have by lapse of time been justified to the letter. We prefer in the present instance to take things as they are, and the conclusion to which one must come is that under the able management of Mr. Parker the corporation has a fine business at Wolverhampton. A concern whose production reaches £175,276 a year is of no mean importance, and is worth holding at considerable hazard. The balance-sheet at this time last year showed output £160,036, while that of two years since can hardly be taken into account, being the first issued under the company's auspices, showed, however, an output of £222,734. These are big figures, and under any circumstances in a properly-conducted business should show a good profit. It rests with the shareholders to enquire into the causes that have necessitated the issue of further debentures, though, no doubt, it is difficult to bring home effectively any remedy. Some one or two directors are made scapegoats, and promises as to future economy are promised. Let us see how the debenture-holders will stand. The present debenture capital is £125,300, the new issue is £100,000—a total of £225,300. The net profits from an output of £175,000 should be ample to pay interest on this amount, so that the issue seems, from a financial point of view, quite warranted, and perfectly safe. The ordinary shareholders are in a troublesome position, but have nothing to gain and may have much to lose by impatient criticism at this moment. After the meeting we may have something to say on the question of their position.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BALANCING ARMATURE REACTIONS.

SIR,—In your issue of December 2nd there is a reprint from an American paper on this subject. The sentence explaining (!) number of balancing turns seems to me to be very obscure: "The product of the armature conductors under a pole into the current in the same is equal to the product of the balancing conductors back of each pole-face in the current (total armature current) through them." Perhaps some of your readers will be kind enough to translate this for me.

I also fail to understand how 58 grooves each ⅝in. wide, = 36·125in., are cut in a core only having a circumference of 22 55in. Or how 100 volts are obtained with 290 wires cutting 400,880 lines at a speed of 60 revolutions per second. I am not writing this with an idea of carping, but to obtain information.—Yours, etc.,

THOS. HY. PADGHAM.

7, King's-terrace, Basford, Stoke-on-Trent,
December 12th, 1892.

THE PRICE OF ELECTRIC SUPPLY.

SIR,—The interesting letter from Mr. Bromley Holmes in your last issue shows very clearly the disadvantages of basing a sliding scale of charges upon the maximum demanded supply when this is taken to mean simultaneous supply to all the lamps, etc., fitted on the consumer's premises. Neither does it appear that the use of a maximum current indicator in connection with each consumer's meters, as suggested by Prof. Kennedy, would quite meet all the difficulties.

We may suppose that by using the heating effect of the current to operate the indicator, or by the use of a dash-pot, the indicator could be made to move so slowly as to prevent the record from being seriously affected by such a momentary current as would be necessary to blow a fuse. Otherwise an accidental short circuit might considerably increase the price per unit for that unfortunate consumer for a whole quarter, and thus lead to undue friction with, if not to sparking at, the collector. It may, however, be said that the ultimate effect would be desirable, inasmuch as it would tend to the more general adoption of such arrangements as would almost abolish the chances of short circuits on any but the smallest branches—*i.e.*, at the lampholders, etc.

We may further suppose that the indicator would be reset at the proper time only, and after its reading had been duly noted by a trustworthy inspector. Even then this system of charging does not always tend to produce the effect to be desired alike in the interests of the supply company and of its consumers—viz., a large load factor.

For instance, churches requiring supply on Sundays only would have to pay the highest rate, but it would be to the interest of the supply company that the rate should be reduced on Sundays in order to develop demand when a large part of the plant would remain idle if the higher price prevailed.

Similarly, during the two summer quarters business places and many other customers would have to pay the higher rate. The demand would thus be repressed in the summer time, when, in the interests of the supply company, it should be developed by reducing the charge. Shop windows would probably be kept alight if supplied at a lower rate after business hours. Motors also would be more extensively used for intermittent work and purposes requiring supply for only one or two hours daily, if the supply were charged always at a low rate, excepting during the time of heaviest demand for lighting purposes. This would frequently result in arrangements being made by consumers to avoid taking supply just at this time, thus increasing the load factor.

From the concluding clause of Mr. Holmes's letter it might be supposed that in matters which affect the system of charging there is no essential difference between the supply of gas or water and the supply of electricity. It may therefore be well to refer to the differences. For convenience, let that portion of the total annual cost which is made up of interest on capital, depreciation, and such other expenses as vary very little with the duration of the demand, be called the fixed expenses.

In the supply of gas and water, owing to the cheapness of storage and the large variation which is allowable in the pressure at the consumer's terminals, a comparatively small increase in the fixed expenses enables the produce of the machinery to be delivered to consumers at 10 times the rate at which it is produced at the works.

In the case of electricity, owing to the lack of any efficient means of modifying the pressure, such as would be

equivalent to the reducing valve commonly used with branch gas pipes and burners, it is necessary to maintain the pressure constant within very narrow limits at the consumer's terminals. For reasons well understood the fixed expenses are proportional, not to the greatest consumption during a period of, say, two days, as in the cases of gas and water, but to the maximum rate of supply provided for, although this rate may be demanded for less than one hour in the year.

Consequently the problem of charges for supply is essentially more complicated in the case of electricity than in the case of gas and water, and the central stations which are able to vary their rates of charge in such a way that their customers reap the benefit of so fitting in their demands as to produce a large load factor will, other things being equal, pay better dividends and develop a larger and more varied demand than the stations with a fixed scale of charges.—Yours, etc., W. B. SISLING.

RE FIRE AT LONDON STEREOSCOPIC COMPANY.

SIR,—Mr Heaphy, in his letter of 6th inst. in your last issue, has taken an exaggerated and erroneous view of my letter to your contemporary. I made the remarks on what I believed to be reliable authority, but as I am not permitted to publish the names of my informants I am bound to withdraw the remarks and express regret for publishing them.—Yours, etc., J. D. F. ANDREWS.

41 and 42, Parliament-street, S.W., Dec. 13.

ECONOMIC POSSIBILITIES OF THE GENERATION OF E.M.F. IN THE COALFIELDS, AND ITS APPLICATION TO INDUSTRIAL CENTRES.*

BY B. H. THWAITE, C.E.

(Continued from page [illegible].)

Artificial Lighting Power Distribution.

The author, in his report on "The Distribution of Fuel Power Gas," demonstrated† that, comparing the cost in value of heat units represented by a given volume of gas for the production of a specific luminous value, the incandescent lamp driven with a gas engine (Otto cycle) is 50 per cent more efficient than a batswing gas burner. This is clearly shown by the graphic diagram. Of course, compared with the recuperative gas burner, the advantage is on the side of the gas. If the price per B.T.U. is reduced to 3d. per unit, the financial advantage will then be entirely in favour of electric energy. A glance at the comparative graphic diagrams, Fig. 2, which the author has drawn up from reliable data, shows clearly that as the cost of production approaches more nearly to that of the admirable Bradford Corporation electric lighting installation example, the reduction of cost of supply will be such as to permit the electric light to be not only the ideal and beautiful light of the fortunate few, but that it will become the ideal and cheap light of the many.

The reports of the cost of transmission given in the appendix show that it will be possible to supply E.M.F. to the metropolis at a price as to permit the electric light supply companies to distribute the light at such a reduction as will permit it to be economically used in comparison with gas, as ordinarily burnt with open flow batswing burner. Of course, it will be unreasonable to expect the electric light companies to be able to reduce their price until the outlay in ways, trunks, and leads shall have become fully utilised; then, with a cheap source of energy, the reduction of cost will follow. In two years or sooner the patent rights relating to the use of incandescent lamps will have expired, and this will alone reduce the cost of the lovely electric incandescent light by at least 10 per cent. Hence, if the electric energy is supplied from a great central coalfield generating station, and its pressure is reduced down to the required voltage of the different town supply companies, the electric light will soon find its way into the cottages of poor and rich alike.

The Metropolitan and Greater London Lighting Companies.

Thanks to wildly reckless speculative and immatured projects, born of greed and inexperience, and the original legislative enactments relating to electric lighting, progress in London has been up to recent times practically crippled; but the lethargy resulting from early disappointments has cleared away like mist before the sun, whose power the electric light surely is, and to-day the metropolitan companies in active operation have already a capital of over three millions sterling, or one fourth of that of the gas companies of Greater London. Up to the last month, over 33 miles of service mains have been laid, and 90 miles of [illegible] been drawn in, and the plan of the giant city shows that [illegible] electric girdle practically embraces the main part of the metropolis, and is sufficient to supply some 360,000 lamps. One company, the London Electric Light Company, Limited, with a [illegible] of £600,000, has already applications for 40,000 8-c.p. incandescent lamps, and 16,000 are already fitted, and it is estimated [illegible] net revenue from the 40,000 lamps will alone be more [illegible] adequate to pay interest on the share capital. In Paris, also, the recent development in the use of the electric light has been very striking and remarkable.

The Choice of the Motive Power Generating System.

One of the fundamental requirements in the choice of a motive power generating system, is a means of rapidly throwing off the total load of work without involving any waste or danger. Where the source of power is the natural waterfall, it is of course, unimportant if the load is suddenly taken off, but with a steam engine plant the sudden stoppage of the engines throws the whole of the generated steam back on the boilers, [illegible] a sudden rise of steam pressure. Besides, the residual heat of the water and fuel is practically lost if the stoppage is for any length of time; and if the power demand is sudden, unless the steam power is continuously kept up, this condition cannot be fulfilled. An ideal method of motive power generating [illegible] should permit the full power of the plant to be obtained in [illegible] minutes at the most. It should also be possible to [illegible] the entire dynamic plant out of action without involving [illegible] strain on any part of the plant; and the whole time [illegible] the plant is in action it should be performing useful work. [illegible] one who understands the characteristics of the two [illegible] and gas engines, will recognise that the only kind of [illegible] able is the gas engine one driven with its own cupola [illegible] fuel gas. There are other considerations in addition [illegible] already mentioned that are of essential importance in [illegible] the ideal system. The fuel power plant should be of [illegible] character that as high a thermo-dynamic efficiency as [illegible] shall be obtained.

The author has tested the relative efficiencies of the gas and steam plant. The economical dynamic fuel power for [illegible] large powers is the gas engine. A consideration of [illegible] economy compels one to insist, as a sine quâ non, that for large powers, in which the consumption of fuel is high, the [illegible] lisable hydro-carbons and the nitrogen associated with hydrogen shall be recovered. Of course, this involves the conversion of [illegible] fuel into a gaseous condition, and this desideratum can be [illegible] with either a steam engine or a gas engine; but it must be [illegible] to the veriest tyro in the science of thermo-dynamics, and [illegible] not be too often reiterated, that the gas thus produced should be burnt in the motor cylinder, and the heat thus directly converted into motion in preference to burning the gas in a steam boiler, which is only too often a monument of inefficiency. In the [illegible] of misty fog suddenly rising the whole of the gas engines [illegible] could be immediately started because the storage of power gas in the gasholder can be established for any length of time without involving any appreciable heat loss or expenditure of labour, and can be utilised by simply the turning of a valve. When any portion of the load is thrown off, an equivalent power gas engine is instantly stopped, and the gas energy flows into the holder until required. The author suggests the replacement for large installations of storage batteries, with gasholders, for the storage of a convertible form of energy, available for use at a [illegible] notice, and involving no loss of energy by storage, for however long a time. Therefore it may be accepted as an axiom, that the ideal fuel power dynamic plant is the internal combustion engine driven with fuel gas stored in a holder, and from which the nitrogenous and other chemical assets have been recovered.

The author and Mr Swinburne in the projects to be described have adopted a character of plant as the ideal method of generating fuel power at the coalfield motive power generating stations composed of the following constituent elements:

1. A gas generating plant of the cupola type, fitted with automatic fuel feeding devices and automatic [illegible] arrangements. The fuel is fed by an electric overhead [illegible] suspension way, or by means of an ordinary electric [illegible] system to coal bins from which it is elevated to the [illegible] and by electric driving gear is then transferred to each cupola.

2. The gas generated is then led through a battery of condensers, in which any atomised fuel carried over with the gas is caught and by which the ammonia is separated as well as the tar. The purified gas is then led through scrubbers of the tower type filled with coke or brushwood, from which the residual tar and ammonia is finally removed. The sensible heat of the gases is then recovered by special means.

3. The gas is then led to the gasholder, and is stored for use. This advantage displaces the necessity for storage batteries. When the holder is raised to a certain height, it automatically turns off the gas generating plant by degrees. A sufficient capacity for emergencies is always provided for.

4. The ammonia water is treated with sulphuric acid by the formula $2NH_3 + H_2SO_4 = (NH_4)_2SO_4$, and the sulphate of ammonia recovered is intended to be sold for agricultural purposes.

Comparative Efficiencies of Internal Power Transmission Arrangements.

The importance of the subject of the transmission of dynamic force to motive elements constituting the industrial plant, has [illegible] quite recently received some of that recognition which it deserves.

* Paper read before the Manchester Association of Engineers.

† "On the Distribution of Fuel and Power Gas," by B. H. Thwaite (*Journal of Gas Lighting, Gas World, and American Manufacturer*, 1892).

The absorption of energy by shafting and belts is not even now properly appreciated. It is only when the dynamometer has been applied, and, better still, since direct driving by electric motors has displaced shafting, gearing, and belting and other methods of driving generally in use, that power users have realised the degree of ceaseless waste in their methods of power transmission.

The displacement by direct electric driving of ordinary shafting and belting methods has resulted in the reduction of power absorption very considerably. M Sarteaux, engineer of the Chemin de Fer do Nord, has recently introduced electric driving at the locomotive workshops at Creil, and he has informed a mutual friend that he has realised a saving in power of 50 per cent. This friend, in a letter, tells the author that some investigations carried out at the Fabrique d'Armes de St Etienne proved that with their then shafting and belting methods of power transmission, not more than 7 per cent. of the power consumed is utilised in doing actual work.

What is the explanation of this extraordinary waste which, if summed up for all our industrial applications, would almost turn the hair of our patriot economists grey? One may venture to suggest an answer: The main shafting, having a potential of dynamic energy equal to the maximum requirements, is always in motion, each bearing surface in its length having a function of energy absorption depending in value upon the character and nature of the frictional surface. Each location of transmission by belting to countershafting is also a point of energy absorption whether the effective part of the producing plant is in operation or not. In dust producing workshops the friction produced by the deposition of dust on the bearing surfaces is alone a factor of explanation, and the loss of efficiency by imperfectly light and

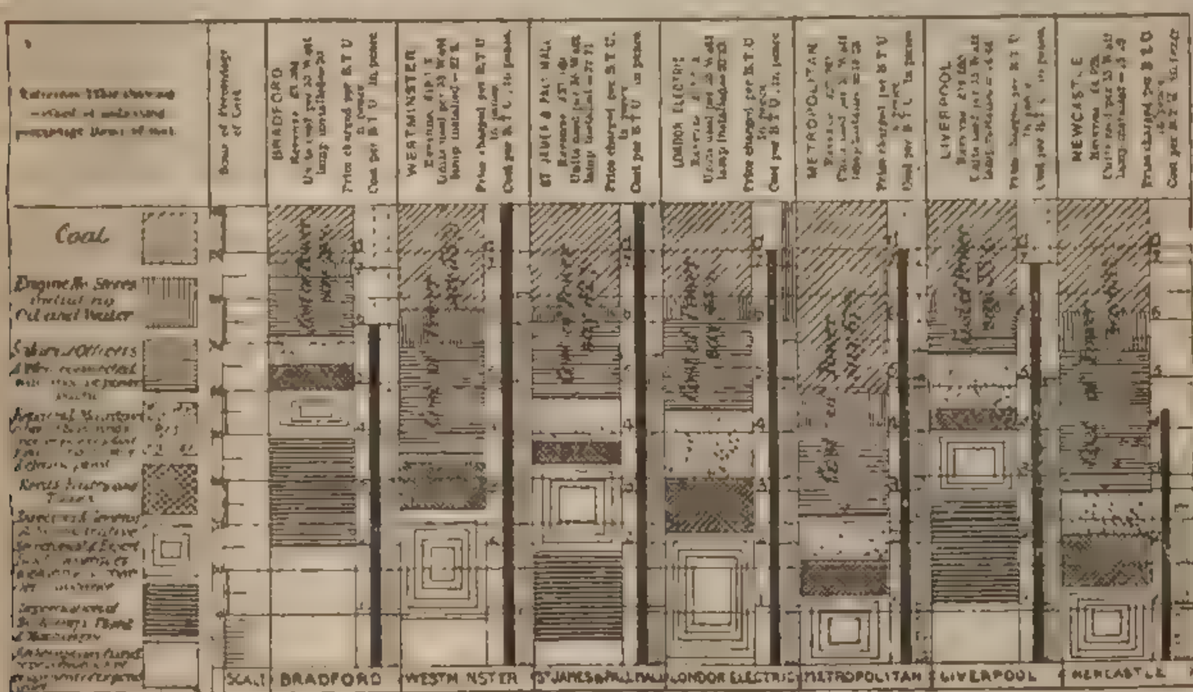

Fig. 2.

unsuitable belting and intra methods of power distribution is also another factor. The gearing elements for diverting the line of power transmission are also absorbers of energy. Individual machines absorb much less power than is generally supposed, and the author urges every power user to ascertain precisely the amount of power absorbed by each of his machines. He would then be cognisant of the running loss by which he is the sufferer.

Since the author wrote the above he has seen the advance proofs of Mr Saxon's useful paper. Mr Saxon pertinently remarks that if the coal consumption were based on actual work done it would give some startling results. There is little doubt but that M Sarteaux's happy experience of a power saving of 50 per cent. by the application of direct electric driving would be experienced by many engineering workshop owners. In Mr Saxon's summary of tests it appears that the average energy absorption percentage for

Spured geared driving is	25·9
Rope geared driving is	29·6
Belt geared driving is	28·6
Direct coupled driving is	23·835

giving a total average of 26·983 per cent. of energy absorbed in internal power transmission work.

On referring to the loss of energy in electric transmission methods, it will be realised that for any ordinary works there would be practically no loss of energy between the motor and the subsidiary industrial machine. The relatively high speed of electromotors is unfortunately not appropriate to existing stationary tools except by the employment of reducing motion pulleys; but there is no obvious reason why the electric motor should not be applied direct to each new and convertible machine, the speed being reduced by helocoidal or other appropriate gear, to satisfy the requirements of the industrial operation. Granting this desideratum, we have at once an ideal method of transmission which has the following series of valuable characteristics:

1. Each industrial machine can be easily and instantly thrown out of dynamic action by the simple touch of a switch.
2. The loss of efficiency in power transmission from the parent motor is almost negligible.
3. No lubrication is involved, nor expensive lubricants.
4. The dangers associated with belt shifting and belting set forth graphically in the author's work * "Our Factories, Workshops, and Warehouses," is entirely removed.
5. In the event of an accident the machine can be instantly arrested.
6. As the power demand is cut off the power supply is reduced in the same ratio.
7. The position of the machine can be altered in any direction considered convenient, without involving the consideration of its effect upon the line of transmission.
8. The danger from fire through over-heated bearings is reduced in a degree depending upon the quality of insulating workmanship and upon the character of the fusible cut off.

The employment of internal electric transmission has been in no instance in this country more fully put to regular use than by the famous firm at Wolverhampton, the Electric Construction Corporation, Limited, and for this progressive action we may thank Mr Thomas Parker, than whom there is no more enthusiastic advocate of the practicable advantages of electricity. Thanks to the courtesy of this firm, we are enabled to realise the extent of their practical patronage to electrical methods of power transmission. The full particulars are given in the appendix; but it may be stated here that with the exception of one defect, that of the retention of intra or subsidiary shafting and belting, the whole of the power is transmitted electrically. The motors are distributed over four acres of ground, the same cables distributing and transmitting the current for the motors also supply the arc and incandescent lamps for lighting the works. All the machine tools, with the exception of a large planing machine and circular saw (which have a motor of their own) are driven from shafting rotated electrically. The 10-ton shop crane is also electrically driven. The cranes travel up and down the shop at the rate of 50ft. per minute, and cross the shop at the same speed. The electric transmission plant has now been running for two years. So far, there has not been any accident, and beyond the usual brush renewals for generating machines and motor transmitters, there have been no repairs required. The firm completely relies on its motors, and has not provided any other means of driving the tools. Not having driven the works by the ordinary methods, the firm cannot make any direct comparison as to power required, but the secretary writes that there is no doubt but that a comparison would come out largely in favour of the electric method.

The De La Vergne Refrigerating Machinery Company, of New York City, have applied in their new works the electric method of transmitting power. They drive their extensive series of planing, slotting, and drilling tools by separate motors of approximate size, gearing down by countershaft and belt; even with this disadvantage they consider that at least 7 per cent. of efficiency is gained, and the cost of maintenance is considerably less.

* "Our Factories, Workshops, and Warehouses: Their Sanitary and Fire Resisting Arrangements," by B. H. Thwaite. London: E. and F. N. Spon, Charing Cross.

The Influence of Electric Transmission of Energy, if generally adopted, on the Atmosphere and on the Conditions of Life in Industrial Centres.

Anyone living in a purely agricultural locality, or in towns like Paris, where the ambient atmosphere is free from the polluted emanations from industrial processes and having the misfortune to be compelled to remove therefrom to towns like Manchester, Bolton, or Oldham, must have been struck with the phenomenally high rainfall average of these towns, and will have noticed the characteristic oily condition of the atmosphere especially on wet and foggy days, and the greasy condition of the pavements. Without going so far as Ruskin, one is compelled to admit that any industrial operation that tends to interfere with natural actions by polluting the atmosphere and altering its degree of humidity, should be carefully looked into, to ascertain if the evil cannot be extirpated. The atmosphere of Manchester having only a moderately high hygrometric character, acts nevertheless in the nature and with the effect of a condenser for the immense volumes of steam sent into the atmosphere from thousands of exhaust pipes, until the ultimate or saturation point is reached, and the atmosphere being unable to hold in suspension this added aqueous vapour, it is released, and the inevitable rainfall of Manchester follows, bringing with it the hydro-carbons belched forth from hundreds of chimneys. These hydro-carbons, along with the lubricant particles associated with the exhaust steam, explain the greasy condition of the mud in the Manchester streets. How different is the early Sunday morn of these industrial centres! Every observer cannot fail to be impressed with the metamorphosis of the atmosphere.

The general distribution of electric energy for light and power, with fuel gas as the general heating agent, would go a long way towards clearing our industrial centres from these depressing conditions, so inimical to healthy vigour of mind and body and lightheartedness, and which conditions, so absurdly out of harmony with the characteristics of our once Merrie England, are not entirely free from responsibility in the cause of our national shame of drunkenness. How different the Manchester of the once great Venetian republic! There the resultant wealth from the sale of the products of the looms of Lombardy actually adorned Nature, and the architectural beauties of the Venetian industrial centres are to-day the joy of all art lovers, in almost spotless condition, except that charming tint due to antiquity; whereas the sculptured work in our industrial centres, as in the instance of Manchester, is simply a hideous caricature of the ideal of its architect-creator. The general distribution and use of electric power as proposed, along with the general employment of gas as the heating agent, would clear away this stigma from our cities and towns, and with it the dirty envelope of soot that, once removed, would, let us hope, never be allowed to clothe up like a deadly pall the beauties of art in stone.

The Hygienic Economy.

The author demonstrated before the Demographic Section of the Hygienic Congress* that the expenditure in making any process or operation of industry thoroughly healthy was money well expended. There is little doubt but that the facility of inducing currents of air, by means of electrically propelled fans removes one of the disadvantages of the electric light, compared with the scientific system of gas burner; but, of course, the electric incandescent (in vacuo) light is far superior hygienically to the naked gas burner. Comparing the two lights calorimetrically, it will be seen that the heat produced for a given lighting or photometric value is far greater in even the scientific or recuperative gas burner than in the incandescent lamp. Besides, with the latter system, there is not the slightest pollution of the atmosphere. These are important advantages, because no cause is more prejudicial to vigour than expanded air resulting from an abnormal temperature. The weight of air (oxygen) passed through the lungs is relatively less, and there is a drop in the animal vigour. The work done is less, and of inferior character. With the distribution of electro-dynamic energy, a simple transformer attached to the service conductor will reduce the potential to the desired voltage degree, either for arc or glow lamps. The increased vigour of the workpeople, due to the pure and relatively thermo-neutral light, its semblance to the natural solar light in its actinic effect, will justify the employment of electric lighting alone, independently of the money value saved. It has been conclusively proved in our Government offices that labour is more efficient and the number of employés can be reduced, by the employment of lighting by electric energy. The question of economy is dealt with elsewhere.

It may, however, be expected that a greater luminous value, as 2·4 is to 7·7, can be produced by burning lighting town's gas in a gas motor, and converting the dynamic into electro-luminous energy, than in burning gas direct by a batswing burner. *Verb sap.*

The Value of a Supply of Economic Electric Energy to Agriculture and Floriculture.

The cultivator of flowers, fruit, and vegetables has a friend in one of the characteristics of the voltaic arc light. This illuminant has an actinic, or chemically active light effect, analogous to the light from unimpeded sunlight. This chemically active characteristic is the motive influence that initiates and stimulates organic life. Ordinary artificial light from gas cannot be said to possess any electro-chemical influence. In the arc light we have nearly all the conditions that could be desired for the cultivation of fruit and flowers. The sun is very sparingly permitted, by the conditions of our climate, to give us a bountiful supply of his invigorating electro-thermo-chemical energy. This has been proved by tests with actinically sensitised paper.

The influence of unimpeded sunlight is brilliantly shown in sunny California, where vegetable organic life is almost wantonly vigorous. It has long been known, since Sir W. Siemens's original experiments in this direction, that the electro-chemical energy of the arc electric light is beneficial to the life and vigour of vegetation, but this beneficent advantage has only recently been put to actual industrial use; and again we have to point to the progressive American for the initiation of a practical commercial application of electro-chemical or actinic luminous energy for the rapid night rearing of fruit and flowers. Were the main high-power electro-conduction trunk lines laid down through the heart of agricultural and pastoral England for the distribution of an additional supply of electro-chemical energy for a line of fruit and flower areas of cultivation, the benefit that would accrue, if properly and adequately utilised, would be an adequate justification for the expenditure. Instead of the ordinary single crops, two, three, and even four crops might be obtained; and instead of our having to import fruit, there should be an excess over internal consumption that would permit an external fruit export trade to be opened up, not to mention the advantages to floral and horticulture.

The Three Projects of Power Transmission.

The author and Mr. James Swinburne have drawn up one report of a project for transmitting power from the South [illegible] shire coalfield to the metropolis. This report is given [illegible] in the appendix, and is shown clearly on the plan of [illegible]. It is, of course, obvious that the same trunk lines [illegible] can be utilised for serving the large towns *en route*, [illegible] Derby, Nottingham, Leicester, Northampton, and Bedford [illegible] suggested that an auxiliary generating station shall be [illegible] South Staffordshire, the trunk line from which shall serve Wolverhampton, Birmingham and the industrial areas in the [illegible] route across to the point where it joins the main trunk [illegible] serving the metropolis.

Two alternate specifications are given in the appendix, one [illegible] Oerlikon Company, Maschinen Fabriken Oerlikon, to whose [illegible] (M. Emil Huber) the author is indebted for much valuable information, and the other is contributed by Messrs. Brown, Boveri, and Company, and Mr. Charles Brown.

The two other projects are for supplying E.M.F. to the [illegible] industrial centres of Lancashire and Yorkshire. For the Yorkshire one the central generating station is located near Barnsley. The direction of the main trunk lines is clearly indicated in the [illegible] transmission. It will be seen to serve the industrial areas between Chesterfield and Sheffield in the south and Leeds in the [illegible], serving the Batley and Dewsbury district *en route*. A branch [illegible] line serves Huddersfield, Halifax, and Bradford, and the adjoining industrial areas.

The loss of efficiencies in the different trunk lines is a negligible quantity, and the interest on cost of mains would almost be [illegible] by the mere cartage to the station in many instances, besides the great advantages already set forth.

The Lancashire project generating station is located near Wigan, and here it may be mentioned that as the great power stations are all proposed to be located in the centre of the coalfields, this would enable the different colliery owners to obtain on [illegible] terms the unquestionable advantage of electro-dynamic energy for traction, pumping, winding, lighting, coal getting, ventilating and drilling purposes.

One trunk line from the Wigan station will serve Bolton, Bury, Heywood, and Rochdale, and a loop line will serve Oldham, Stockport, Macclesfield, and Manchester. Another trunk line will serve Blackburn, Preston, and Clitheroe. A loop line [illegible] will serve Accrington, Burnley, and the Rossendale and Haslingden [illegible].

A trunk line passing south from the station will [illegible] St. Helens, Warrington, Runcorn, and Widnes, and a loop line will continue along the Ship Canal to serve the future industrial area of progressive Lancashire.

The author forecasted in the *Builder* 10 years ago, that once the canal was made, its banks would become the future area of new industrial developments, and with a line of power supply, a perfect railway connection, and a means of [illegible] it may be stated that no other area in the world would offer such facilities for cheap industrial production as this area with the [illegible] supply of cheap electric and unlimited energy proposed.

To realise the marvellous industrial fecundity of Lancashire and Yorkshire let us look at the diagram showing the proposed lines of electric power transmission as well as the state of the [illegible] system at present established. Here we have the nervous centres of industrial life before us at a glance, the very acme of economy in transmitting thought. Let us go a step further and assist Nature by laying down a nervous industrial system to [illegible] power, and the picture, with the Ship Canal complete, [illegible] and would be worthy of the enterprise of the counties of the Red and White Rose.

(To be continued.)

PHYSICAL SOCIETY.—November 25, 1892.

Prof. S. P. Thompson, D.Sc., F.R.S., vice-president, in the chair.

Messrs. T. J. Fry, A. G. Bessemer, jun., and E. F. [illegible] d'Albe were elected members.

The following communication was made: "**Experiments in Electric and Magnetic Fields Constant and Varying**," by Messrs. Rimington and Wythe Smith. In the first set of experiments shown, exhausted electrodeless tubes and bulbs were [illegible]

* "The Economics of Industrial Hygiene." The *Proceedings* of the International Congress of Hygiene, 1891.

rapidly in a constant electric field between two parallel-charged discs. Double fan-shaped images were produced by the tubes, due to the displacement currents which pass to equalise the potentials at the ends of the tubes. These fans were not symmetrical with respect to the lines of electric force, but were displaced in the direction of rotation. In explanation of this phenomenon it was pointed out that as a tube rotated the potential difference between its ends increased, until this difference was sufficient to break down the dielectric in the tube. The discharges would therefore pass at the ends of the intervals, during which the difference of potential was rising, and consequently the images would be displaced from the symmetrical position in the direction of rotation. The number of discharges produced during one revolution was found to depend on the strength of the electric field, but not on the speed of rotation, and that end of the tube which was approaching the negatively-charged plate appeared brightest. These experiments were referred to as examples of the direct conversion of mechanical energy into light. Instead of rotating tubes in a constant electric field, the tubes were next kept stationary, and a varying electric field produced by connecting the plates with an influence machine allowed to spark. Under these conditions the tubes and bulbs were seen to glow. Using large suspended plates charged by an induction coil, long tubes were caused to glow brightly even at considerable distances away from the plates. The glow could be apparently wiped out by passing the hand along the tube. Another series of experiments were performed in varying magnetic fields. With a view to showing Hertzian phenomena to large audiences, the authors tried Geissler tubes to replace the spark gap in resonators, with great success. When large Leyden jar circuits were used, the effects were very brilliant. Another form of resonator consisted of a bent wire terminating in two plates, between which an exhausted tube was placed. This tube became luminous when the resonator was placed in the vicinity of a fairly large Hertz oscillator. Other experiments, similar to those shown before the society by Prof. J. J. Thomson at Cambridge, on discharges in exhausted bulbs were then made, the bulbs being placed with a coil of wire of four turns forming the connection between the outer coating of two small jars, whilst sparks passed between knobs connected with the inner coatings. The bulbs glowed brightly at each discharge rings of light being seen near their inner surfaces. On putting a ring tube outside the coil, this was also seen to glow. The most brilliant part of the glow always occurred in close proximity to the wire coil. A secondary coil wound by the side of the above-mentioned primary could be short-circuited at will; this had the effect of decreasing or extinguishing the luminosity in the bulb or tube. Bright sparks passed between the secondary terminals when held a short distance apart, but the shock experienced by touching the ends was not serious. The above arrangement, with the addition of two Geissler tubes placed in series between the outer coatings of the jars, was used to illustrate the fact that closing the secondary diminishes the impedance of the primary circuit of a transformer. Experiments on condensers made of tinfoil or glass were shown. In one of them, parts of the coatings, in the form of letters, had been removed, and the spaces became luminous when the condenser was connected with an induction coil. In another experiment a glass plate was moved to and from a condenser, and a musical note could be heard whose pitch increased as the distance between the glass plates diminished. The note was said to be the octave of an open organ pipe whose length was equal to the distance between the plates.

CHELTENHAM.

[Four reports have been issued as to this lighting: (1) that of the committee, (2) preliminary by Prof. Ayrton, (3) final by Prof. Ayrton, and (4) by Mr. Hall. The final report of Prof. Ayrton we give herewith, reserving that of Mr. Hall for our next issue.—ED. *E. E.*]

The two main points to be decided on with reference to the electric lighting of Cheltenham are the system of distribution to be adopted, and the site to be selected for the central station. As intimated in my previous report, I am of opinion, for the following reasons, that a low-pressure system, radiating from a single generating station, could not economically be employed in supplying electric light to Cheltenham: 1. The private lighting, for some time to come, will probably be scattered. 2. The size of the area to be ultimately lighted is large; hence, a high-pressure system with some plan of transformation must be employed. If direct current be employed, the only methods of transformation must consist in using either accumulators or motor-dynamos. With accumulators, or storage cells, I have had much experience from about 1881, when I was appointed electrician to the Faure Electric Accumulator Company, on the first introduction of commercial accumulators into England. The experiments that I have from time to time carried out show that the methods of manufacturing accumulators have been steadily improved, and samples of one of the latest forms, which I tested this year, I found to be vastly superior to the earliest commercial specimens on which I experimented in 1881. But, in spite of these improvements, accumulators are inferior to motor-dynamos in all three particulars—prime cost, cost of maintenance, and efficiency when used to convert electric energy at high pressure into electric energy at low. These two systems of direct-current transformation have had a fair trial in the district allotted to the Chelsea Electricity Supply Company during the past three or four years, and, to an important extent in that district, accumulators have been replaced by motor-dynamos. A motor-dynamo, as its name implies, is a combination of a motor with a dynamo. The motor is constructed to be worked with a small current at high pressure, and drives a dynamo which is constructed to generate a large current at low pressure. Two commutators with two sets of brushes must be employed with the combination, and, if the plan of banked transformers be adopted (so that whatever power is required at any particular time the transformers in use at a sub-station are working at nearly full load, and, therefore, at nearly maximum efficiency) there would be several motor-dynamos—that is, several pairs of commutators and sets of brushes at each sub-station. Now, although it is possible for several motor-dynamos to run satisfactorily for several hours without being touched, no engineer would like to trust the lighting of a district to the running of high-speed machinery without supervision. Hence, if motor-dynamos be employed it would be necessary to have an attendant at each sub-station, or at any rate to arrange that attendants should pay frequent visits of inspection to the sub-stations. If, on the other hand, alternate current be used, the transformer becomes a stationary piece of apparatus consisting simply of two coils of insulated wire (one composed of a long thin wire and the other of a short thick wire), wrapped round pieces of laminated iron. The transformer requires, of course, no oiling nor trimming of brushes as with a motor-dynamo; further, the full pressure between the mains can be switched suddenly on to an alternate-current transformer, whereas with a motor-dynamo resistance coils must be employed and gradually withdrawn from the circuit to allow the pressure to increase slowly as the machine gets up speed. It is therefore not necessary for the person who desires to alter the number of alternate-current transformers in use at any time in a sub-station to enter the vault in which the transformers are banked; all that need be done is to turn a switch let into the surface of the road or pavement, just as a turncock turns on or off the water. The following calculation gives a fair notion of the difference in the first cost of plant (irrespectively of mains, buildings, etc.) for transforming 96 kilowatts, or the amount of power sufficient for about 1,450 incandescent lamps of 16 c.p., or for about 2,500 incandescent lamps of 8 c.p. Transforming by means of:

Accumulators (two sets being required)	£7,000
Motor-dynamos	800
Alternate-current transformers	330

The prime object of using transformers at all arises from the fact that the pressure that can be used in a house is limited by law, and by the present construction of the incandescent lamp, whereas the higher the pressure that is maintained between the supply mains the smaller is the current required to convey the power from the central station, hence the smaller may be the cross-section of the copper for a given percentage of loss of power arising from resistance. Now, whereas in consequence of the risk of flashing from one brush to the other across the commutator (about 1,000 volts is the maximum pressure for which motor-dynamos have been constructed), transformers for alternate currents are in use for 2,000, 5,000, and 10,000, and even a larger number of volts. Two thousand volts can, therefore, be used with alternate-current transformers without any risk of a breakdown, and the copper of the supply mains kept to half the cross-section that would be necessary if a pressure of only 1,000 volts were employed. Further, as regards the generating dynamo itself, there need be no commutator, and, indeed, there need be no moving parts at all at a high pressure if an alternate current be produced. This greatly facilitates the steady production of high pressure. Consequently there are several reasons in favour of employing alternate current. The main objection at the present day arises from alternate-current motors not having been brought to the same perfection as direct-current motors. I am inclined to think that this is but a temporary disadvantage, since the large amount of attention that is at present being directed to alternate-current machinery will in all probability lead to considerable improvement in alternate-current motors. But in any case, as the demand for motive power in Cheltenham will probably be small, the question of greater or less efficiency possessed by small direct and alternate current motors is comparatively unimportant compared with the main consideration regarding a cheap and efficient supply of electric light. Another objection that might be urged against the use of alternate current is that there is no method of storing power similar to that afforded by accumulators in the case of direct currents. In the early days of electric lighting the advantage of having a reserve of power that could be drawn on in the case of a breakdown of the electric machinery was invaluable, but with the improvements that have been introduced into the construction of dynamos, etc., and by the employment of several dynamos, and, if desired, of separate steam engines on the same central station, and by the steam-pipe being arranged so that the steam can enter at either end, the risk of a total breakdown has been rendered almost nil. Another advantage derived by the use of accumulators is that the boiler fires need not be kept up during the slack portion of the 24 hours, the electric power sent into the mains being then taken from that stored in the accumulators. But with a destructor, where refuse has to be burnt whether power be required or not, the importance of economising fuel and labour during the periods when electric light is required by the town is much smaller. And it is to be noticed that in a recent report which Dr. Oscar von Muller and Herr Baurath Lindley have made on the future electric lighting of Frankfort, they have strongly recommended the employment of alternate current, as they conclude that the advantages far more than counterbalance

the disadvantages. Further, the two companies—the Brush Electrical Engineering Corporation and Messrs. Laing, Wharton and Down—between whom the electric lighting of the City of London has been divided, have both adopted alternate currents for house and shop lighting. I am, therefore, of opinion that for the electric lighting of Cheltenham an alternate-current system should be employed, the power being sent along the supply mains from the generating station at a pressure of not less than 2,000 volts, and that for domestic and shop lighting the pressure should be reduced by banked transformers at sub-stations to not less than 110 volts. If 100-volt lamps were employed, the mains would require to have 10 per cent. greater cross-section than would be necessary with 110-volt lamps. The advantages of erecting the central generating station at the destructor, rather than at the central depot, are: (1) Power to the extent of about 70 h.p. day and night in the winter, and about 30 h.p. day and night in the summer, is available from the burning refuse. If it may be regarded that from this source an average of, say, 40 h.p. day and night throughout the year is available, then taking the price of coal at only 10s. per ton, and assuming that only 4lb. of coal need be burnt per hour to generate 1 h.p., the burning of the refuse instead of an equivalent amount of coal will represent a yearly saving of £313 on the coal bill. (2) Economy in labour and supervision, since two entirely separate staffs will not be required at the destructor and at the central station. (3) The saving of some £1,000 that would have to be spent in building a tall chimney at the central depot, if that site were selected for the generating station. (4) The nuisance from smoke issuing from the chimney outside the town would be comparatively small. (5) Land near the destructor can be obtained when required at a comparatively low price for an extension of the central station. The advantages of erecting the generating station at the central depot are: (1) About £900 would be saved in the cost of the cables and conduits required during the first year or so, and about £1,600 in cables and conduits during the first 10 years. (2) One shilling and sixpence per ton would be saved in the price of coal. As regards advantage No. 1 in favour of the central depot site, it is to be noticed that it is practically balanced by advantage No. 3 in favour of the destructor site. The practical importance of the second advantage—the saving of 1s. 6d. per ton of coal—depends, of course, on the total consumption of coal per year. If the yearly consumption were to be the same at one site as at the other, the diminished price of coal at the central depot would undoubtedly be an important advantage in its favour; but the 70 h.p. day and night during the winter, and the 30 h.p. day and night during the summer, developed by the burning of the refuse, will alone be enough for the day and the midnight electric lighting of the borough for some time to come. We have, therefore, to consider the extra cost per ton of coal burnt at the destructor, and compare it with the total cost of the extra amount of coal that would have to be burnt at the central depot. It is probable that for some time to come the average power required for the three busy hours of the evening will not exceed 100 h.p. throughout the year, or, in other words, that the extra power that will have to be developed at the destructor by the burning of coal will not exceed, and probably will be considerably less than, 60 h.p. for three hours per night. This, at 4lb. of coal per hour, represents an annual consumption of 117 tons of coal at the destructor, on which the extra cost would be £8. 15s. 6d., at 1s. 6d. per ton. But this extra cost is insignificant compared with the £313 per year saved on the coal bill by the burning of the refuse. Indeed, even when the time comes that 500 h.p. will be required for three hours per night on the average (corresponding with the supply of current to about 5,000 incandescent lamps of 16 c.p., or about 10,000 incandescent lamps of 8 c.p.), the extra cost of the coal burnt at the destructor will not amount to one quarter of the total saving arising from the burning of the refuse. Further, it must not be forgotten that the land at the central depot may in time become very valuable for business purposes, and therefore that it would be unwise to use it for an electric light station, which certainly need not be placed in the heart of the town. From a financial point of view, therefore, it seems quite certain that the destructor site, and not the central depot site, should be selected for the generating station. And even apart from these financial considerations, I could not advise the Corporation of a residential town like Cheltenham to erect what, at the best, is nothing more than a somewhat noisy factory with possibly smoking chimneys in the centre of one of the best districts. The preceding pages of this report were written before the 7th inst., when I received Mr. Hall's report, dated the 1st inst. This report of Mr. Hall's is a supplement to his previous one, necessitated by the Electric Light Committee having decided to adopt arc lamps rather than incandescent lamps for outdoor lighting (after seeing the experiments which I suggested should be carried out before a decision was arrived at). Placing arc lamps in the middle of the roadway in the Promenade would be most economical as regards light, but as centre pillars are out of the question from an artistic point of view, it would be necessary to resort to the ancient method of lighting streets—viz., to suspend the lamps by chains over the middle of the road. This would of course necessitate two iron pillars, one on each side of the roadway, for every arc lamp used, and as an arc lamp and lantern are somewhat heavy the pillars would have to be strong, and therefore would be somewhat costly, especially if ornamental. Further, since the main object of changing from gas to electric lighting in the Promenade is not because the present gas lighting is very inefficient, but in order to obtain a more picturesque and brilliant effect, the mere saving in electric power does not appear to me to be the main consideration in this particular instance. Now the effect of arc lights among trees covered with leaves is extremely pretty, and if the number of arc lamps (22) proposed by Mr. Hall were increased to 25 or 28, the lighting of the road and paths would be [illegible] number of lamps were used, and the lamps were placed on posts between the trees. I would therefore recommend that [illegible] of placing the lamps be carefully considered before a decision is arrived at. As regards the High-street and similar places, the method of slinging the lamps from chains suspended across the street and attached to the buildings on each side has many advantages. The chief disadvantage is the interference of the chains with the rapid transit of a fire escape, but, in a town like Cheltenham, which presumably has not a number of fire engine and escape stations, and, therefore, where escapes coming along the road to all parts of the town need not be anticipated, as in London, this difficulty might easily be overcome. I observe that Mr. Hall, in this supplemental report of November 1st, proposes that the excavation of the roads and the making of conduits, the fixing of the copper strip in the low-pressure districts, and the wiring of the arc lamp pillars, shall be done by Corporation workmen. The excavation and the building of the conduits might be well carried out in this way, but unless the Corporation can succeed in securing the services of really skilled jointers—a somewhat difficult task, as skilled workmen are already in the permanent employ of electrical contractors—there is great risk of the joints being faulty; and it has to be most carefully remembered that a joint which may be perfect from a purely mechanical point of view, may, in consequence of a [illegible] having been introduced in the [illegible], or in consequence of the insulation not having been properly carried out, be most defective from an electric point of view. The larger portion of the work Mr. Hall quite rightly proposes to have done by contract. The drawing up of the various specifications for the different parts of the work will have to be most carefully done, first so as to secure uniform excellence, and at the same time so as to allow each contractor to use the special apparatus and machinery which he is accustomed to employ, and so that the tenders may be properly compared with one another when received. Frequently, due to want of precision in the specification, tenders differing widely in amount are sent in by different firms for the same nominal piece of electrical work, whereas the highest tender may not be the dearest, as the particular firm submitting that tender may [illegible] include far more than, or intend to do the work in a [illegible] superior manner to, another firm submitting a much lower tender. For the first year's running Mr. Hall estimates that [illegible] tons of fuel will be required. This appears to me to be [illegible] high. For incandescent lamp lighting he estimates that [illegible] Board of Trade units will be required during the year, in addition to the maintenance of the 28 arc lamps. This latter I [illegible] will not consume more than some 6,500 Board of Trade units, so that a supply of some 74,000 Board of Trade units will be consumed during the first year. Mr. Hall estimates that 60 h.p. to 70 h.p. will be available at all times from the burning of the refuse; in this report I have estimated this at an average of 40 h.p. at all times, but taking Mr. Hall's figure of 60, then this will require to be increased by perhaps another 60 h.p. by the burning of coal during the four busy hours of the evening. The total number of Board of Trade units thus delivered during the four [illegible] evening hours alone amounting to about 70,000, or nearly the total estimated supply. But at 8lb. of coal per horse-power, which is a high rate of consumption for a condensing steam engine, this 60 h.p. for four hours per night throughout the whole year, only amounts to some 300 tons during the first year. Mr. Hall's much higher estimate of the first year's coal consumption is, however, a fault on the right side, since the demand for private and shop lighting may at first not be quite as large as is assumed in Mr. Hall's estimate, and therefore the first year's financial result will probably not be worse, and may perhaps be better than he estimates it. The introduction of electric lighting into shops and private houses is very much a matter of fashion. There are parts of London supplied by a public electric lighting company where rows of shops may be seen still lighted by gas, while at other spots may be seen a row of shops every one of which is fitted with the electric light. If, then, the fashion of using the electric light be judiciously set at Cheltenham, there is little fear that at the low price of 6d. a Board of Trade unit, and still more at the still lower price of 5d. a unit, the electric light will be generally adopted in the richer parts of the town. For it is to be noted that this latter price is lower than that charged in any part of London, the lowest price yet charged in the city being 6d. per Board of Trade unit for electric lighting in the St. Pancras district. It would be well when the time comes, by means of a lecture or by other suitable means, the public be taught that the nominal light given by a five-cubic-foot gas burner does not apply to ordinary ungoverned burners, but only to special forms not generally found in houses. And, therefore, that the cost of lighting with common house burners is much larger than might be imagined by using the nominal candle-power of gas burners. I do not think that any fear need be felt regarding improvements in electric machinery rendering obsolete in a few years the best apparatus of to-day. So much attention is now being directed to electric lighting that improvements are sure to be effected; but if the Corporation of Cheltenham can provide the inhabitants with a good light and earn a dividend for some years to come, it will be of little consequence that the machinery now to be bought can, when worn out, be replaced by better. A fair sum should, of course, be set aside for depreciation, and this has been done in the estimates I have just submitted to you. Whether this sum will ultimately be spent in purchasing machinery exactly like the original, or machinery possessing [illegible] improvement in no way affects the wisdom of now introducing the electric light.

NEW COMPANIES REGISTERED.

Hove Electric Lighting Company, Limited.—This Company has been formed, with a capital of £40,000 in £5 shares, for the purpose of taking over from the Commissioners of the town of Hove, Sussex, the undertaking comprised in the Hove Electric Lighting Order for 1890. The undertaking comprises the right of supplying electricity for public and private lighting and heating, and as a motive power, throughout the whole of the town. The prospectus states that nearly one-fourth of the capital has already been subscribed by the Directors and their friends. The Directors are: Colonel A. J. Filgate, R.E., 106, Jermyn-street, W.; Colonel H. Wood, C.B., 95, Thorpe-road, Norwich, vice-chairman; H. A. Hoare, Esq., The Hill, Hampstead, N.W.; Carleton F. Tufnell, Esq., A.M.I.C.E., Lloyds, London; John Wilkes, Esq. (managing director of John Wilkes, Son, and Mapplebeck, Limited, Birmingham). Consulting engineers: Messrs. Crompton and Co., Limited, Mansion House-buildings, London. Secretary: Francis R. Reeves, Esq., M.I.E.E., F.I.S. The offices of the Company are Mansion House-buildings, London, E.C., and 79, Western road, Hove, Sussex.

Scottish House-to-House Electricity Company. — The prospectus of this Company has been issued with a capital of £100,000 divided into 20,000 shares of £5 each, of which 19,900 are ordinary shares and 100 are founders' shares. The profits of each year are applicable first to the payment of a dividend at the rate of 7 per cent. per annum on the amount paid up upon the ordinary shares, and, subject to the memorandum and articles of association, one-half of the profits thereafter remaining belong to the holders of the ordinary shares, and the other half to the holders of the founders' shares. An issue of £30,000 in 6,000 ordinary shares of £5 each is now asked for, the lists closing on Monday, December 19. The Directors are: Peter McLagan, Esq., M.P., D.L., J.P., Calder Hall, Mid Calder, N.B.; John Hannay, Esq., Powton, Garlieston; George Flett, Esq. (Messrs. Dick, Kerr, and Co., Limited), London and Glasgow; W. D. Cairney, Esq., C.A., George-square, Glasgow; Timothy Bost, Esq., 33, Renfield-street, Glasgow. The consulting electrical engineer is W. A. Bryson, F.R.S.E., M.I.E.E., Glasgow. This Company holds a provisional order from the Board of Trade, confirmed by Act of Parliament, giving it the right of supplying electricity throughout the whole of the burgh of Coatbridge, a district, the prospectus states, eminently suited for the electric light in consequence of the large number of iron works and other industrial enterprises there carried on.

Walsall Electrical Company, Limited.—Registered by Frith Needham, 10, New-inn, Strand, W.C., with a capital of £10,000 in £10 shares. Object: to acquire as a going concern the business of a manufacturing electrician and electrical engineer, now carried on by Frederick Brown, Walsall, Stafford, and at Birmingham, under the style of the Walsall Electrical Company, in accordance with an agreement expressed to be made between Frederick Brown of the one part and this Company of the other part, and to develop and carry on the same. There shall not be less than three nor more than five directors. Qualification, £250. Remuneration, £1. 1s. each for each Board attendance, not to exceed 13 guineas each per annum.

COMPANIES' REPORTS.

THE ELECTRIC CONSTRUCTION CORPORATION, LIMITED.

Directors: Sir Daniel Cooper, Bart., G.C.M.G. (chairman), J. Irving Courtenay, Esq. (vice-chairman), Sir Henry C. Mance, C.I.E., George Dibley, Esq., Henry P. Holt, Esq., Joseph Moseley, Esq., James Pender, Esq., John B. Verity, Esq. Works Director and Chief Engineer: Thomas Parker, Esq., M.Inst.C.E., M.I.E.E.

Report of the Directors to be submitted to the shareholders at the ordinary general meeting, to be held at Cannon-street Hotel, E.C., on Friday, the 16th December, 1892, at 12 noon.

The Directors beg to report that, notwithstanding many unexpected difficulties which were encountered during the last 12 months, the result of the year's working shows a satisfactory balance to the credit of profit and loss account. The profit for the year is £46,693. 11s. 7d., after deducting the expenditure on plant, machinery, and patents, paying the interest on debentures and other loans, and placing a sum of £10,000 to a reserve for bad and doubtful debts. Including the balance of £10,721. 19s. 4d. from last year, there is a surplus to be dealt with of £57,415 10s. 11d. The amount of work executed during the last 12 months compares favourably with that of previous years. The contracts with the Liverpool Overhead Railway Company, Limited, and the South Staffordshire Tramways Company, have been nearly completed. The Liverpool overhead line is expected to be in full working order by the end of the year, and the Staffordshire electric tramway has already been passed by the inspector of the Board of Trade who has expressed himself thoroughly satisfied with the system employed and the work done by this Corporation. A very successful system has been carried out for lighting the city of Oxford, and the Directors have every reason to believe that these important works will serve to bring large additional contracts to the Corporation. During the past year valuable experiments have been carried out at the laboratory of the Corporation at Bushbury in connection with the present methods of producing zinc, chlorine, and alkalies. Mr. Parker considers the results which have been obtained highly encouraging, and a company has been formed for the purpose of commencing the manufacture on a commercial scale and to demonstrate the value of the patents. Of the preference shares offered for subscription 2,926 shares were taken up. The capital thus provided has not been sufficient for the purposes of the Corporation. With a view, therefore, to improve its general financial position the Directors have consulted the Electric and General Investment Company, Limited. That company has obtained a special report from the auditors, Messrs. Broads, Paterson, and Co., and has also caused an examination to be made of the works and plant at Wolverhampton by Messrs. Wheatley Kirk, Price, and Goulty, who have reported generally on the manufacturing business of the Corporation. As a result of obtaining these reports and of their own investigation of the affairs of the Corporation, the Electric and General Investment Company, Limited, has agreed to issue £100,000 additional capital for the further development of the business, and has guaranteed that the subscriptions shall not be less than one-half of the issue. Such additional capital to be raised by the issue at par of second mortgage debentures of £10 each, bearing interest at 6 per cent. per annum, and redeemable, at par, by half-yearly drawings over a period of about 15 years, and entitling the holder, by way of bonus, to an income bond of like amount, carrying interest as from the date of the redemption of the corresponding debenture at a rate for each year equal to the dividend declared on the ordinary shares for the preceding year. In order to secure for the shareholders the full benefit of this arrangement, the Directors have stipulated with the Electric and General Investment Company, Limited, that the whole of the debentures shall be allotted to the shareholders in proportion to their respective holdings, and a circular carrying out this arrangement is sent herewith. All allotments not taken up by the shareholders or their nominees on or before the 19th inst. will be cancelled. In accordance with the understanding arrived at with the Electric and General Investment Company, Limited, the Directors do not propose that any dividend be paid upon the ordinary shares for the past year, but they recommend that the dividend at the rate of 7 per cent. per annum be paid on the preference shares up to 30th September last; that £30,000 be placed to a suspense account, and that the balance of £26,862. 1s. 5d. be carried forward. Several retirements from the Board have taken place during the year, and, as arranged with the Electric and General Investment Company, Limited, the Right Hon. David Plunket, Q.C., M.P., 12, Mandeville-place, W., and Mr. James W. Barclay, 5, Clarendon-place, Hyde Park, W., have been elected directors and will take their seats after the general meeting. The directors who retire by rotation are Mr. James Pender and Mr. John B. Verity, who offer themselves for re-election. The Directors are determined during the ensuing year to give their special attention to effecting economies in the expenses of administration, and they rely upon the next account showing material retrenchments in this respect, and that no occasions will arise for the exceptional expenditure shown in the accounts for the past year. They are confident also that the additional capital proposed to be raised for the purpose of developing the manufacturing business will be the means of largely increasing the net profits. Messrs. Broads, Paterson, and Co., the auditors, retire, but offer themselves for re-election.

PROFIT AND LOSS ACCOUNT FROM OCT. 1, 1891, TO SEPT. 30, 1892.

Dr.				£	s.	d.
Expenses and cost of production during the year ended 30th September, 1892, at Wolverhampton, including engineering department and laboratory expenses				149,776	13	7

BUSINESS NOTES.

Bridgend. – The Bridgend Local Board have decided to apply for a provisional order.

Halifax. It is practically decided to light the new hospital at Halifax with electric light.

Edinburgh. – A deputation has been appointed to visit towns provided with electric light.

Penarth. A committee has been appointed to go into the question of electric lighting at Penarth.

Roumania. Tenders are required by January 10, 1893, for the lighting of Turn Severin, Roumania.

Blackpool. The Corporation has granted an extra allowance of £30 to Mr. Hesketh, their electrical engineer.

Newport. The Newport County Council have agreed to ask Prof. Robinson to report upon the electric lighting.

Eastern Extension Telegraph. The Directors have declared a quarterly interim dividend of 2s. 6d. per share, payable on the 15th prox.

Shirley. At Shirley (Hants) Local Board, when the lighting came up for discussion, Mr. Olds expressed his desire to have the electric light.

Windsor. The town clerk has been instructed to take action against the Windsor Electric Light Company for breaking up the streets without authority.

Aston. The Aston Local Board are obtaining information to make up a complete report on the electric lighting question, Mr. Booker having the matter in hand.

Dover. At the last meeting of the Dover Town Council the electric lighting agreement was brought up and read, and the Mayor said the work would now go on.

Western and Brazilian Telegraph Company. – The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £2,865.

Rothesay. The Rothesay Town Council have agreed to appoint a committee to confer with the Harbour Committee to enquire and report on the cost of electric lighting the harbour and esplanade.

Bolton. The final report of the sub-committee on electric lighting is to be given shortly. We understand it [illegible] low pressure within the compulsory area and high pressure outside.

Sutton Coldfield. The borough surveyor of Sutton Coldfield in his report says that he trusts during the next year to see the Town Hall lighted by electric light by means of the turbines at Powell's Pool.

Chiswick. The Chiswick Local Board have not yet settled their arrangements with Messrs. Bourne and Grant on the [illegible] of electric light, and it is highly probable that the Board will readvertise.

Popp Company. The Paris Compressed Air Company [illegible] appears, passed into the hands of MM. de Bramens [illegible] the first attending to the electrical and the latter the [illegible] departments.

Taunton. The enquiry on Taunton electric lighting [illegible] which was to have taken place on Tuesday, has been [illegible] (Friday). As the question has been much debated an [illegible] meeting is expected.

Portsmouth. The tenders for central station plant [illegible] Portsmouth must be sent in by January 5. Plans and [illegible] can now be obtained (two guineas deposit) on application to Mr. Alexander Hellard, town clerk, Portsmouth.

Accumulators. M. Philippart has, according to the *Intermédiaire*, again taken up the manufacture of the [illegible] Sellon Volckmar accumulators. M. Gadot has taken [illegible] manufacture the same accumulators at his factory in the [illegible] Tourquoink.

Hampstead. The Electric Lighting Committee of the Hampstead Vestry has recommended the Vestry to undertake the [illegible] of electric lighting in the parish, under the powers [illegible] obtained from the Board of Trade, and to borrow [illegible] necessary plant.

Sheffield. The Electric Light and Power Company have given notice to the Sheffield Highway Committee that they [illegible] lay underground mains in certain streets. The committee [illegible] mend that notice of disapproval be given in accordance with the company's order.

Edinburgh. The Lord Provost's Committee of the Edinburgh Town Council at their meeting last week, remitted to [illegible] committee to take steps for giving effect to the provisional order on electric lighting obtained last year, and to call in expert [illegible] to their assistance.

Welsh Board Schools. – At a meeting of the Llangeinor School Board at Blaengarw, on Wednesday, Mr. [illegible] was decided to have the Wyndham School, Nantymoel [illegible] electricity, and also to have the new school building at Tynewydd fitted up with an installation.

Bristol. At the meeting of the Town Council on Tuesday the report of the Electrical Committee stating that Messrs. W[illegible] and Rawson declined to carry on the [illegible] recommending that the tender of Messrs. Aben and [illegible] be accepted, was considered and adopted.

Sheffield. Mr. Johnson, writing in answer to a [illegible] states that powers have been obtained, a site [illegible] the pit's mouth, with plenty of condensing water. The engine and boiler houses are to be enlarged and rearranged, the [illegible] underground mains has been sanctioned, and work will be begun in January.

Eccles. – At the monthly meeting of the Eccles Town Council the town clerk placed before the members a proof of the [illegible] provisional order for electric lighting, providing for the [illegible] a limited area within two years. The town clerk's [illegible] the subject was ordered to be printed and a copy [illegible] each member.

Dundee. At a recent meeting of the Lighting Committee of the Dundee Police Commission, it was [illegible] for the illumination of the central portion of the High [illegible] electricity. It was reported that the new light [illegible] probably cost £110 as against £70 for lighting the same portion of the street with gas.

Edison-Swan Company. – This Company have opened depots in Liverpool, Birmingham, Newcastle, Leeds, Hull, Cardiff, [illegible] and Dundee, and are about to open similar depots in [illegible] towns of the United Kingdom, for the supply of lamps [illegible] wires, cables, etc. These depots have been opened for the convenience of the trade only.

Paisley.—The tenders for the lighting of Paisley having been before the Council, and Mr. Bryson, the engineer, having given his opinion thereon, it was agreed to correspond with the parliamentary agents with the view of obtaining an extension of time for carrying out the provisions of the order.

Great Eastern.—The Great Eastern Railway Company are going to borrow £250,000 for improvements, among which are £15,000 for electric lock and block working; and £30,000 for the electric lighting of Liverpool-street Station and Hotel, the Bishopsgate passenger and goods station, the Bethnal Green passenger station, and the Spitalfields goods station.

St. Louis Electric Railway.—It is announced authoritatively that the General Electric Company of America has no idea of backing the St. Louis electric railway scheme financially, though it would be glad to get the order. The railway companies' stock is, however, being taken up fast, and construction work and the purchase of sites for power stations are going on satisfactorily.

Electric Block System.—The Great Western Railway Company have established their improved electric block system at Menheniot. Under the superintendence of Inspector Scantlebury, the signal boxes, lights, and lines have been adopted to the new plan, able assistance having been given by Inspector Gatfield, of Teignmouth, and Mr. Collam, of the railway company's electric staff at Plymouth.

Clifton Rocks Signals.—The contract for the erection of the electric signals in connection with the Clifton Rocks Railway has been secured by Messrs. King, Mendham, and Co., Western Electrical Works, Bristol and London. The arrangements to be made include means for signalling from the lower end to the top, the number of passengers to be carried up the railway each journey, replying and starting signals, and telephones.

Stafford.—The report of the Stafford Electric Lighting Committee, recommending the Corporation to take active steps for the provision of electric light, was adopted at the last monthly meeting of the Town Council. The cost of an installation for 3,000 lamps is given at £20,000; it would require 2,000 lamps to make it pay, and there is reason to believe 1,500 would be taken from the start. The Corporation own the gas works.

Redruth.—The Redruth Electric Light Supply Company's application to the Local Board to lay wires has been granted. The proposed capital of the company will be £10,000, an admirable site has been arranged for, and provisional agreements have been come to with leading engineers for the supply of plant. The current will be supplied on the low-pressure three-wire system, with accumulators. The three directors making arrangements are Messrs. R. H. Michell, E. Tangye, and C. Tweedy.

Morecambe Electric Light and Power Company.—The second ordinary meeting of this Company was held at Morecambe on Tuesday, Mr. W. B. Hodgson presiding. A dividend of 5 per cent. was declared as the result of the first year's working. The retiring director, Mr. W. C. Farrar, and the auditor, Mr. Duff, of Halifax, were reappointed. Mr. Wm. Morgan having resigned, Mr. Twycross was elected director in his place, Mr. W. Holdingworth and Mr. Wm. Wilson being also added to the directorate.

Scarborough.—The shares forming the recent issue of capital of the Scarborough Electric Supply Company were allotted last week. Actual work will now be commenced at once but it is anticipated that the light will be turned on in June next, by which time it is expected there will be a considerable demand for current. The alternate-current system will be employed with 1,000 volts pressure on the high-tension mains. Mr. A. A. Campbell Swinton has been appointed managing director of the Company.

Brighton and Hove Electric Light Company.—This Company announces that it is prepared to receive applications for £7,500 first mortgage debentures at par, being the balance unissued of a total issue of £15,000 of such debentures. The debentures are of £100 each, carrying interest at the rate of 6 per cent. per annum, and are convertible into ordinary shares, at the option of the holder, at any time on one month's notice. The business of the Company was established in 1882, and the Company itself was incorporated in 1885.

Ipswich.—At the meeting of the Ipswich Lighting Committee a letter was received from the Board of Trade asking if the authority desired to make any observations on a letter which they sent to the Ipswich Electric Supply Company pointing out that the company had failed to satisfy the Board of Trade that they were in a position to discharge the duties and obligations of the Electric Lighting Order of 1891, or make the deposit required by sec. 7, and that they propose to revoke the order. It was resolved that the Authority had no observation to make.

Nottingham.—The Nottingham Corporation on Monday decided to undertake the electric lighting of the borough, dealing first with the central area, at a cost of £50,000. The site suggested, which was in a good part of the town, was objected to, as it would cost tens of thousands of pounds, and several other sites, one belonging to the Corporation, were proposed. Sir John Turney explained that although other sites might be cheaper, they would entail more expense by reason of distance from the centre of the town. The scheme as recommended in the report was adopted.

Appointments.—The following are extracts from the minutes of the London Electric Supply Corporation: "Major C. B. Waller was elected to a seat on the Board in place of Mr. Arthur F. Wade resigned, and it was resolved that the thanks of the Board be given to Major Waller for his services as manager and secretary to the Corporation during the past five years; also, in view of the faithful and able services of Mr. R. Stewart Bain to the Corporation, it was resolved that Mr. R. Stewart Bain be appointed secretary of the Corporation in combination with his present duties as accountant."

Birkenhead.—At the monthly meeting last week of the Birkenhead Town Council, the Finance Committee recommended that the chairman (Alderman Deakin), deputy chairman (Mr. Goetenhofer), and Messrs. Widmer, J. Laird, Bloor, and the Mayor, be appointed to negotiate with the representatives of the Brush Electrical Engineering Company, Limited, and any other company, body, or person in reference to the proposed transfer of the powers of the Corporation under the Birkenhead Electrical Lighting Provisional Order, 1890, and that they be authorised to obtain professional advice and assistance if necessary or desirable.

City Lighting.—The amendment moved by Mr. C. T. Harris at the last meeting of the Commission of Sewers asking that a report on the subject of the electric lighting of the City streets should be referred back for further information, was carried by 22 votes to 11. The primary objection Mr. Harris has to the proposal that the side streets should be lighted by incandescent lamps is that it is an extravagant mode of outdoor lighting, and will greatly increase the original cost of the scheme; and, in the absence of any definite information as to comparative cost, Mr. Harris contends that the Commissioners are not justified in proceeding with the work.

Compagnie Electro Mecanique.—The French company of J. J. Heilman and Cie. have lately united with several other influential firms or companies, and formed a new company under the title of "Compagnie Electro Mecanique," with a capital of 1,000,000f. The following are associated with the new company: For boilers, engines, dynamos, and cables, Weyher and Richemond, Menier, Belleville, Brown Boveri, Edison, Societe Generale des Telephones, J. J. Heilmann; electric tramways, Ch. Brown. The office is 30, Rue de Grammont, Paris. Installations for the distribution of power and lighting on the Brown system are being carried out in the towns of Reims, Le Mans, and Narbonne.

Elmore's Foreign and Colonial Patent Copper Depositing.—The accounts for the financial year of the Company ended December 31 last show a balance at that date of £132,263. The Directors, in their report, state that they cannot at this time recommend the payment of a dividend, but they hope to be able, in the course of 1893, to make a distribution to the priority shareholders, leaving a handsome amount in hand for distribution among the founders. At the present moment, taking the Company's assets at par value, and after setting aside £5 per share and a fourth of the balance of the priority shares, or an extra £2. 15s. per share, there remains an amount equal to £13 per share for the founders.

Partnership.—Messrs. Waller and Manville inform us that they are about to enter into partnership with Mr. Joseph Kincaid, M.I.C.E., and that in future their business will be carried on under the style of Kincaid, Waller and Manville. Our readers are well acquainted with Mr. Kincaid's name as an engineer of considerable eminence, and Messrs. Waller and Manville are to be congratulated on the advantage their clients will derive from their association with him. This arrangement will come into effect on January 1st, 1893, when the offices will be at Mr. Kincaid's present address, 11, Great George-street, London, S.W. (telephone No. 3,011, telegraphic address, "Kincaid, London."

Electric Tramways.—Mr. J. Clifton Robertson, the tramway engineer, in his report to the Plymouth Corporation, considers the use of electric traction. He alludes to the 300 street railways in America, aggregating 3,000 miles in length, successfully worked under nearly every known condition of gradient and climate. He advocates overhead wire construction, the cost for poles, wire, and connections not exceeding £500 per mile. An extract from this report urging the use of electricity, published by Messrs. Casey and Clay, solicitors, of 21, St. Andrew's-street, Dublin, is being circulated in the Pembroke, Blackrock, Kingstown, and Dalkey townships. A perspective view accompanying shows the proposed Dublin electric tramway in action.

Electric and General Investment Company, Limited.—This Company has been authorised by the Directors of the Electric Construction Corporation, Limited, to issue to the existing shareholders of the Corporation £100,000 in second mortgage debentures to bearer of £10 each in proportion to their respective holdings. The debentures, which carry interest at 6 per cent., rank next after the £150,000 of first mortgage debentures already existing. They are redeemable at par by half-yearly drawings extending over a period of about fifteen years, £10,000 being set aside annually for interest and redemption purposes; and the subscriber for each debenture will receive, by way of bonus, an income bond for a like amount carrying interest from the date of redemption of the corresponding debenture at a rate equal to the dividend declared on the ordinary shares for the preceding year.

Cost of Electric Light.—The *Scotsman* has a careful technical explanatory article on electric lighting, units, and measurement, going into the necessary knowledge required by a householder. "All things considered," says the writer, "it may be safe to say that for ordinary house lighting, electricity at 4½d. per unit costs about the same as gas at 3s. 6d. per 1,000 cubic feet. There is one connection in which electric lighting will be cheap at any price. Brilliant illumination seems nowadays to be an essential feature of all busy shops, and what with early darkness and late closing numerous gas jets so alter the condition of the air in many of them that an hour in the evening is more trying to the shop assistants than three hours in the morning. With electric incandescent lamps the heat will to some extent remain—in these days it is not amiss—but the air will not become converted into slow poison."

Catalogue of Art Fittings.—There are some pretty designs shown in a catalogue of fittings which we have received from the

Electrical Company of 122 and 124, Charing Cross-road. No. 2,608, a three-light pendant, is of quite noticeably satisfactory design for the centre of a hall or drawing room. A simpler form to be recommended consists of three flint glass pans or flexible cords, separated out by a light framework of hammered metal. A good selection of wrought-iron pendants is given for single lamps or for several, and a number of small brackets, both simple and highly wrought, give considerable scope for selection. Some handsome figure standards will be very suitable for artistic rooms. The Eastern lady, carrying her parrot, and holding aloft her torch electric light, is very effective. The scope for these kinds of standards is growing, and gives an admirable outlet for the designs of good artists in small bronzes and statuettes.

Crompton Electric Supply Company of Australia.—The third annual general meeting of the shareholders of the Crompton Electric Supply Company of Australia, Limited, will be held at the registered offices of the Company, Mansion House-buildings, in the City of London, on Monday, the 19th day of December inst., at 3 o'clock. This meeting is called in compliance with the articles of association, but as the Directors have not yet received the audited statement of accounts from Sydney to the 31st May last, the end of the Company's financial year, it will be impossible to lay them before the meeting, and therefore a resolution will be proposed adjourning the meeting to await the arrival of the accounts. Mr. W. Trotter, J.P., chairman of the Australian Committee of the Company, is at present in London, but is leaving again for Sydney at the end of the month. He will attend the above meeting and make a verbal report to the shareholders on the position and prospects of the Company.

Barnet.—At the last meeting of the Barnet Local Board the memorial to the Board of Trade asking for the necessary powers to carry out a scheme of electric lighting in the district was brought up to receive the seal of the Board. Mr. Schmidt took exception to clause 10, which is as follows: "To exempt the Board from the obligation to supply electricity for public or private purposes in such portion or portions of the said area of supply or under such conditions or circumstances as may be specified in the order." The clerk said the form was exactly as prescribed by the Board of Trade rules. Mr. Schmidt said the clause in question was not in the Act of Parliament. It seemed contrary to common sense to get a provisional order, and that then the Board should not be obliged to supply private or public customers under certain conditions. Mr. James said he looked upon the clause as one which would be called "a saving clause." Mr. Widdicomb moved, and Mr. Wynne seconded, that the seal of the Board should be affixed to the memorial. The motion was carried, Mr. Schmidt refraining from voting.

New Swindon.—"Dynamo," writing from Birmingham to the *Swindon Advertiser*, says: "I notice that your paper, together with the *Contract Journal* and other mediums of advertising, announce that the Swindon New Town Local Board invite tenders for the lighting by electricity of their district from January 1, 1893. Is it not possible there is some mistake here, and that the date 1893 should read 1894? If not, I am amazed at the ignorance displayed. Nine days is certainly short enough time to obtain all necessary details to enable firms to seriously tender, but this is nothing compared with 10 days in which the fortunate firm must buy land, lay out their depôt, build engine and boiler house, put down engine and dynamos (which are not usually kept in stock on shelves, like sugar and sides of bacon), fix lamps in, I believe, 20 miles of streets, and have the whole system working to satisfaction. The whole thing is a farce on the face of it, and if the date is correct, the only conclusion that can be come to is that the advertisement is not a serious one." We can hardly believe ourselves that the thing was meant seriously; it might, however, give a chance to "installations in a fortnight" engineers.

Wolverhampton.—The Lighting Committee presented a report at the last meeting of the Wolverhampton Town Council with regard to electric lighting. They stated that they had received 15 tenders, and the following six were selected for consideration: The Electric Construction Corporation, high pressure continuous currents, £28,614 10s.; ditto, alternating currents, £29,525; Messrs. Siemens Bros., £27,105 5s., and £29,345 5s.; Messrs. Crompton, high pressure alternating, £28,628 10s.; and the Brush Electrical Engineering Company (high pressure alternating), £31,229 10s. Taking into account the future working expense of the scheme, the committee decided in favour of the Electric Construction high pressure tender. In addition the committee suggested that Mr. W. H. Preece, F.R.S., be appointed engineer for the carrying out of the scheme at a remuneration of 5 per cent. upon the works included in the accepted tender, and that the Finance Committee be empowered to raise sufficient Corporation stock for the financial requirements of the enterprise. The report was accepted, but owing to the lateness of the hour when it came forward it was decided to discuss the matter at a meeting to be held on Monday.

What do Companies Supply?—A case was tried at the Ipswich County Court on Wednesday, before his Honour Hugh Barclay Wilson, Esq., involving a principle of electric light supply which may affect some companies. A customer was sued for a sum for renewal of lamps. The defendant said the bill he agreed to settle was for light, not renewals and so forth. The Judge expressed the opinion that the lamp was a necessary part of the apparatus for producing light. The representative of the supply company maintained their business was to supply "electricity, and not light." The Judge said it was clear that there was a misunderstanding—the company sold electricity while the customer ordered light. But the globes were as necessary to produce the light as the electricity. There was no analogy between gas and electric light, as gas would burn without a proper burner. The company replied that electric light could be produced by a simple [illegible] tion of the wires. His Honour: "But you don't suppose a [illegible] would stand holding them together?" The defendant said he had several renewals before the company charged him at all, and he took the light on the understanding he was not to pay for fittings. The company's representative said this was for exterior fittings only. The Judge decided for the defendant with costs, and in answer for leave to appeal on account of the principle involved, said he thought the appeal would not lie, as the company had given the customer to understand they would keep up the light.

Neuchatel.—We mentioned last week the competition opened for projects for transmission of power of the River [illegible] to Neuchatel. The generating station will be situated at [illegible] Clees, and the turbines will give 900 h.p. at minimum and 2 [illegible] at maximum. Tenders will be required for turbines, dynamos and mains. The following are the particulars of the water power: Head available, 56 metres; flow, maximum 5,000, mean [illegible], minimum 1,700 litres per second. Dynamos will be coupled to the turbines to supply (*a*) electric lighting for Neuchatel, [illegible] nine kilometres from the station at Pré aux Clees; (*b*) [illegible] of power in Neuchatel Serrières; (*c*) eventually of [illegible] lighting and power distribution along line of route, [illegible] other localities adjacent; (*d*) for electric tramways and [illegible]. Applications of current for (*a*) and (*b*) only are to be [illegible] at present, and particulars for these only will be at present [illegible]. A jury of the following gentlemen will make the award: [illegible] Hirsch, director of the observatory and president of the Water Power Commission at Neuchatel; Dr. H. F. Weber, professor [illegible] Zurich Polytechnic; G. Colombo, professor at Royal [illegible] Institute, Milan; Oscar von Miller, engineer, of [illegible]; and R. V. Picou, electrical engineer, of Paris. Prizes of 5,000f., [illegible] and 3,000f. (£200, £160, and £120) will be awarded for the [illegible] best schemes, which will remain the property of the [illegible] Neuchatel. These must be sent, with motto, by January [illegible]. Particulars and sketch plan can be obtained by application to "Direction des Travaux Publics, Neuchatel, Switzerland."

London Electric.—A distinct feeling of satisfaction is [illegible] electrical circles at the appointment of Mr. H. F. Lewis [illegible] the Western Telephone Company) as general manager to the London Electric Supply Corporation. Mr. Lewis, who did so much for working up the business of the telephone company, will evidently be the right man to work up and direct the [illegible] business of the London Electric, and that very much can be done in this direction everyone will admit. The company [illegible] lamps equal to over 50,000 lamps of 8 c.p. connected, and [illegible] has been going well for some time past. Complaints, of which mention has been made, on the score of price against other [illegible] panies, have induced several large consumers to revert to the [illegible] company, and, curiously enough, with the result at the [illegible] nominal price per unit of a reduction of some 20 or 25 per cent. in the total quarter's rent—at least, so the account reaches us from a trustworthy source. Some rearrangements have recently been carried out at Deptford, and a new engine and dynamo of the [illegible] venient size of 300 h.p. have been put in. The engine is of the triple expansion vertical type, by Messrs. Plenty and Co., of Newbury, and the dynamo is as before a Ferranti alternator. The two old sets from the Grosvenor, each of 625 h.p., have been also set to work for some time back at 2,400 volts, transforming up to 10,000 volts for transmission. These are besides the two large engines of 1,250 h.p. at 10,000 volts, which are now running satis[illegible] factorily. We do not expect that any very decided [illegible] will take place in the general arrangements of supply, nor will sub-station distribution be introduced to any extent at the present moment, but the new type of transformers are being [illegible] put in with considerable saving in loss from magnetising [illegible]. The company can supply double their present load without extension of machinery, and there is evidently plenty of scope for active pushing of the business.

Ashburton Technical Workshops.—Ashburton Technical Workshops, just completed, are an extension of the Ashburton Grammar School, wherein the students will receive practical instruction in analytical chemistry, engineering, and blacksmithing, carpentry, and joinery. The buildings have been specially designed to fulfil the requirements of the Devon County Council and the Science and Art Department, and consist of [illegible] laboratory 30ft. long by 17ft., which will be fitted up with all the latest conveniences and improvements for the thorough teaching of chemistry in all its branches, practical and theoretical, [illegible] ing some attention to electricity. There will be bench accommodation for 16 students, and each will have gas, water, [illegible] burner services, and pneumatic troughs. In a [illegible] is a capital fume closet for the escape of any noxious gases [illegible] during the experiments, the gases being conducted through a glazed flue into the furnace chimney. The laboratory is [illegible] and light, and ventilation has been amply provided for. The [illegible] of the windows, including those in the lantern light, are [illegible] hung and work easily by cords. In the engineering shop, [illegible] accommodation is provided for practical instruction in [illegible] and blacksmithing, there being a [illegible] forge [illegible] shop and a forge hearth to take [illegible] and assaying on the other side, both flues being [illegible] the furnace chimney. The carpenters' shop [illegible] room, well lighted, and well ventilated, and benches will be provided for 16 students. The buildings have been erected to the entire satisfaction of the grammar school governors by Mr. [illegible] Stevens, contractor, of Ashburton, from plans drawn in competition, and which were prepared by his assistant, Mr. Fred [illegible], who has superintended the execution of the work. The [illegible]

County Council deserve credit for the thorough way in which they appear to be attacking the question.

Glasgow Tramways.—The following letter in advocacy of the cable system of traction from a correspondent signing himself "Well-Wisher," appears in the *Glasgow Herald*: 'Sir,—I am sure the ratepayers must feel grateful to you for the trouble you have taken in collecting all the available information as to the comparative merits of the different mechanical systems now operating the tramways of this and other countries. Your general finding in the matter seems to be that you advise that the cable system should be adopted on all the routes where the traffic is of a heavy nature, and that the overhead wire electric system should be introduced where the traffic is under a certain figure. The Tramway Trust may, however, fall into serious error if they base their decisions rigidly upon this principle, without considering other modifying local conditions. It must be remembered that the cable system was first introduced in the streets of San Francisco not for the purpose of overtaking heavy traffic, but to operate the cars over its steep tramway routes. In working cars on a tramway line with heavy inclines there must be a certain additional power expended over and above that necessary to propel similar cars on a level route, and in considering whether the traffic is or is not above a certain standard the extra power required to operate the cars alone must necessarily be added before the actual requirements of the particular route can be ascertained. Thus the Springburn tramway route, over which there is at present an eight-minute service of cars, although recognised as a good paying line, is perhaps the most expensive route to work in the city on account of its heavy gradients, and this point should be well considered before determining how it is to be worked in the future. I have very little faith in the electric system, as yet developed, for working heavy traffic, or for operating moderate traffic over heavy inclines; and I therefore think our Tramway Trust would act prudently in adopting the cable system for the Springburn tramway route." With reference to which we may point out that sufficient examples already exist of electric traction on heavy inclines in the United States for there to be any absolute need to leave electricity out of the question in this case.

Clapham to Paddington.—The Joint Select Committee appointed this year to join with a Committee of the House of Lords to consider the subway railway schemes within the limits of the metropolis were "convinced that direct communication through London for the main railway lines north and south of the Thames, whether for the convenience of their country or their suburban passenger traffic, would be of undeniable utility to relieve the overgrown passenger traffic along the chief thoroughfares, to provide for the natural expansion of London, and to check the congestion of our metropolitan population, by means, as Mr. R. M. Beachcroft in his evidence before the committee described, 'to facilitate a transference of the population out into the suburbs,' and to control and regulate workmen's trains in the public interests." The proposed railways, which the committee's report dealt with, were confined in their objects to meet the wants of the City and Charing Cross centres, but did nothing to provide for the north and south communications of West London. A scheme is, therefore, now on foot to promote a Bill in Parliament to provide direct and rapid means of transit between Paddington, the terminus of the Great Western Railway, and the great populations therein and north of the same, and South Kensington, Brompton, Chelsea, Battersea, Wandsworth, Clapham, and the districts which already have railway communication with Clapham Junction, the point where the L. and S. W. R. and L. B. and S. C. R. enter London. The report of the committee is to the effect "that the evidence submitted to them was conclusively in favour of the sufficiency and special adaptability of electricity as a motive power," and "that the methods of cable traction appear also to be of recognised utility," thus proving that the use of steam locomotives, while being impracticable in deep subways, is entirely unnecessary. The proposed line will follow, by means of a deep tunnel, on Mr. Greathead's well-known system, a route which lies very nearly due north and south, and will have intermediate stations at or about Uxbridge-road, Kensington-road, Cromwell-road, Old Brompton road, Fulham-road, King's-road, Cheyne-walk, Battersea Park, Battersea-road, Wandsworth-road, Clapham-road. It will also have covered means of access to various important centres.

Leith.—At the monthly meeting of the Leith Dock Commission, the minutes of the Works Committee showed that the question of having an installation of the electric light in the docks had been considered. The committee, while not prepared to recommend an introduction of the whole system, were of opinion that it should be introduced at or near the Victoria Dock; that to that extent it be remitted to the committee with full powers to carry out; and that meantime the superintendent be directed to consider the details of the work with a view to reporting thereon. Mr. Currie said the committee saw, with the present unfinished condition of the works on the east side of the harbour, the difficulty of making arrangements for a complete system of light on that side, and that there was also the further question as to whether the best site for the installation necessary for that side of the harbour would not be on part of the ground which was proposed to be reclaimed. They thought it would be inexpedient to attempt to deal with it until, at least, plans were further advanced with respect to the new dock. They saw no such difficulty with regard to the west side of the harbour, where the installation would be of a less extensive and costly character, inasmuch as the space to be lighted was very much smaller. It had also the advantage of being part of their works where a large amount of work was done—in fact, a larger amount of revenue was derived there than at any corresponding space under their jurisdiction. They therefore came to the conclusion that it would be of advantage to initiate the system on the west side of the harbour, and they would have the advantage of any experience. The committee had no intention of hurrying on with the work with any view of getting it done during the present winter. They thought it would be expedient to make all the arrangements for carrying it out during the summer, so as to be in readiness for the winter's work. They would also have the benefit of the action of the Edinburgh Corporation on the matter of electric lighting. In the course of his subsequent remarks, Mr. Currie mentioned that the total cost of the whole work was estimated at £8,000, but the cost of the portion proposed to be at once introduced would probably be between £2,000 and £3,000. The minute was approved, Mr. Currie explaining that two installations were to be made—one on the east side and one on the west side.

York.—The electric lighting at the York Courts of Justice was successfully inaugurated on Thursday, the 8th inst. The City Council or their engineer, Mr. Creer, were wise in having the new courts wired for the electric light instead of fixing up gas fittings. It is proposed eventually to take the supply of current from the mains of the city supply, but as the scheme is not yet completed a temporary plant has been provided and fixed in the basement corridor of the building. We have already mentioned this installation, but the following fuller details will be interesting. The corridor has been partitioned off, so that a very pleasant little machine-room has been made. The plant consists of a Crossley 18 i.h.p. gas engine and a Crompton dynamo capable of supplying current for 220 16-c.p. lamps. A temporary switchboard, with instruments, cut-outs, switches, etc., has been fitted up, and neat iron rods on uprights have been fixed round machine and engine. Altogether, for a temporary job, it looks very well, and has the appearance of having been carefully carried out. The building is wired and fittings in for over 500 lights, but for the present only 200 or 220 will be required at any one time. The principal switchboard is in the porter's office, and from this the current is distributed through the main circuits, the ground floor, with the courts, the first floor, the fire brigade department, and police quarters being the principal. Each of these circuits are subdivided into the usual smaller circuits. A five-light electrolier adorns the entrance hall, and the main corridor is served by three light electroliers. Three-light clusters under white glass shades are hung with silk flexibles in the sessions court and police court, and movable standard lamps are provided for the judicial benches. The clock tower contains 24 16-c.p. lamps. Lanterns on brackets are provided outside the main entrance to the courts, each containing three 16-c.p. lamps; the glass in lanterns might with advantage be a little clearer. The entrance to the police and fire brigade quarters are also provided with similar lamps. The drill yard is well lighted, and the police cells are each provided with a lamp having a reflector, giving a good light through the thick glass window into the cell. The wiring and the fittings of the building have been carried out by Messrs. Benham and Sons, of London, to the specification of Mr. Sydney Hargreaves, and the machinery by Messrs. Crompton and Co., under the supervision of Mr. B. H. Jenkinson. Mr. Creer, the city surveyor, deserves complimenting on the successful results of his labours.

Southport.—Colonel John Ord Hasted, R.E., Local Government Board inspector, held an enquiry at the Southport Town Hall on the 8th inst. respecting an application of the Corporation to borrow £28,000 for works of electric lighting. The town clerk (Mr. J. Davies Williams) supported the application, and among those present were the Mayor (Councillor Hulme), Alderman Griffiths, Alderman Hacking (chairman of the Electric Light and Gas Committee), Councillors Travis, R. Watson, Hesford, and several of the corporate officials. The town clerk stated the application was for the purpose of enabling the Corporation of Southport to carry out upon a progressive basis a provisional order which was granted to it in 1891. The area which was included in that provisional order was of an exceedingly limited extent, and when the matter was taken in hand it was seen that to comply with that which was compulsorily imposed upon the Corporation would not be a wise policy, so that the Electric Lighting Committee in formulating a scheme took into consideration the present and the near future requirements of the town. The plant proposed to be laid down would be sufficient to cope with a demand up to 6,600 16-c.p. lamps, provided first with certain additional engines and boilers in a building and additional distribution of mains laid in the town. Were they to confine themselves only to the present requirements of lighting they would only want 1,200 16-c.p. lamps, and there would be little saving in the items which make the expenditure in respect of the 6,600 greater than there would be for 2,000 only. Unless provision was made to meet the increasing demand which they anticipated, they could not expect the electric light to be properly appreciated in the locality. If they confined themselves to 2,000 16-candle light power, they contended that it would be unsuccessful from a financial point of view, because they were justified in expecting a large demand for the electric light from the large number of the population who resided in high-class houses. The method they proposed to adopt was to have the site of installation a considerable distance out of the town on account of the nuisance which might arise—viz., on the gas estate at Blowick. As to the question of mains, it was intended to take down two high-tension trunk mains, one in the direction of the business part of the town and the other in the direction of the residential part. The system to be adopted was not yet decided upon. The Local Government Board had given them permission to adopt either the alternating or the continuous

high current system, and he thought the latter would be decided upon if the transfer of the land could be acquired. Alderman Harking then gave evidence and stated that there had been 400 applications received for the supply of electric light from different institutions and business places in the town. It was probable that the principal streets would be lighted by the system. After further evidence the enquiry was concluded, there being no opposition.

Glasgow.—The central electric station which the Glasgow Corporation have in hand is rapidly approaching completion, and it is believed that the current will be ready to be supplied to private customers by Christmas. The station at Waterloo-street has been ready for some time, and the machinery is in a forward state, though all the engines are not yet erected. The station is a handsome building with a frontage over 90ft. in length and three storeys in height. The engine room occupies nearly the whole width of the site on the ground floor. The boiler house extends backwards from it at right angles at the west end—making an L-shaped erection—and above it is the accumulator room, where the storage cells are placed. Plant has been put in at first sufficient to supply 12,000 8 c.p. incandescent lamps, but the site contains space for appliances for 40,000 8 c.p. lamps. At present there are in the boiler house five steel boilers of the marine type 10ft. in diameter and 12ft. in length, having a working pressure of 160lb. to the square inch. These supply steam to seven Willans central valve compound engines, two of these being of 80 h.p., two of 150 h.p., and three of 250 h.p. These are to drive direct seven dynamos, continuous current, simple shunt wound. Two of them have an output of 400 amperes at 120 volts, two an output of 400 amperes at 230 volts, and three an output of 670 amperes at 230 volts. The buildings are very substantially constructed. The main walls are of stone, the division walls of brick, and the floors of concrete on iron girders, while iron is employed for the support of the roofs. The apartment measures upwards of 72ft. in length by 32ft. 10in. in width. The engines and dynamos are situated somewhat below the level of the street, and the switch gallery is at one end of the room. A powerful travelling crane, stretching over the engines at a considerable elevation, will make it possible to handle the machinery with great ease. The battery room, which is 49ft. by 29ft., contains two complete batteries, each of 57 cells, one for the positive and the other for the negative side of the current. The upper floors of the main building have not yet been subdivided, but it is understood that they will be used for office purposes and the storage of materials. The system of distribution adopted is the three-wire system at 200 volts. The five feeder mains leave the generating station. The mains consist, as now usual with this system, of copper strips 1in. by ⅛in. or ¼in. wide, carried in cast-iron culverts, formed in sections 4ft. 6in. long. They are 22in. in width and 6in. deep. The conductors are supported in the culverts on a series of porcelain bridges or insulators placed at a distance of 4ft. 6in. from each other, and arranged so as to carry the strips of copper ribbon without contact. Two porcelain tiles equally spaced are placed between the insulators to prevent the copper conductors, should they sag, from touching the iron and making contact with earth. To avoid possible danger from water leakage the culverts are protected by arched cast-iron covers, to which they are closely jointed by means of red lead putty. The sections are attached to each other with bolts and spigot and faucet joints, thus making the culverts water-tight from end to end. Any moisture finding its way in, either as the result of drainage or condensation, will run down to manholes, which are placed at intervals of 60 yards, and at the corners of each street, and will be pumped out if necessary. Where an abnormal amount of water can collect, a connection will be made with the city drains. The conductors have been made sufficient to meet all present requirements, but in the event of an increase of size being called for more copper strips can be run in without disturbing the pavements. Bare copper conductors have been laid wherever practicable. In the course of carrying out the work, however, it has been found that there are a great many more cellars below the pavement than were anticipated, and the conductors in many cases had to be laid in the roadway. The conductors here used are insulated cables carried in cast-iron pipes, as the culverts would have had to be put at an inconvenient depth in order to sustain the heavy traffic of the streets. The feeders consist partly of heavy copper strip in culverts and partly of Siemens armoured cables laid in wood troughing in the earth. Four miles of culvert have already been laid, while cables in pipes make three more miles of conductor. The copper used already amounts to 30 tons, and as much more will be required before the network at present proposed is complete. The streets which are to first receive the light will take a total of 106 arc lamps, placed on cast-iron columns at a height of 18½ft. above the level of the pavement. The cast-iron pipes to be used for the street lighting mains have been laid alongside the private supply mains, but the streets are expected to be lighted after the private customers have been turned on.

PROVISIONAL PATENTS, 1892.

DECEMBER 5.

22261. **Improvements in electric arc lamps.** Arnold Frank Hills, 6, Bream's buildings, Chancery lane, London.

22271. **Improvements in and connected with carbons for electric arc lamps.** Charles Walter Hazeltine, Norfolk House, Norfolk street, Strand, London. (Date applied for under Patents Act, 1883, Sec. 103, May 6th, 1892, being date of application in United States.)

22274. **A new or improved shade or screen for electric and other lights.** Edwin William Streeter, 76, Chancery lane, London.

DECEMBER 6.

22285. **An improvement in microphone transmitters.** George Lee Anders and Walther Kottgen, 10, Jeffreys-square, St. Mary's axe, London.

22308. **Improvement in incandescent electric lamps.** Eugene Walter Applegate, 321, High Holborn, London. (Complete specification.)

22333. **Improvements in ammeters and voltmeters.** Emil Hartmann, 21, Finsbury pavement, London.

22344. **Improvements in galvanic batteries.** William Walter and Frank Richard Wilkins, 128, Colmore row, Birmingham.

22346. **Improvements in telephonic switching apparatus.** [illegible] Davis Miller, 62, St. Vincent street, Glasgow.

22375. **Improvements in the method of welding or working metals electrically.** William Phillips Thompson, 6, Lord street, Liverpool. (Charles L. Coffin, United States.) (Complete specification.)

DECEMBER 7.

22422. **An improved automatic electrical call apparatus principally for use in telephone circuits.** Nat Kh[illegible], [illegible] Wilson street, Derby.

22473. **Improvements in dynamo electric machines.** Charles Eugen Lancelot Brown, 46, Lincoln's inn fields, London.

DECEMBER 8.

22534. **Improvements in musical instruments operated by electricity.** Paris Eugene Singer, 6, Victoria road, Kensington, London.

22589. **Improvements in electric switches.** William M[illegible] Mordey, 46, Lincoln's inn fields, London.

DECEMBER 9.

22615. **Improvements in electric current meters.** Michael Dr[illegible] Field, 96, Buchanan street, Glasgow.

22639. **Improvements in glass vessels for accumulators.** [illegible] Kroeker, 433, Strand, London. (Complete specification.)

22657. **A new or improved electric accumulator.** James [illegible] Lorrain, Norfolk House, Norfolk street, Strand, London. (Marius Dumont, France.)

DECEMBER 10.

22690. **Improvements in musical instruments actuated by electricity.** Paris Eugene Singer, 6, Victoria road, Kensington, London.

22719. **Improvements in street boxes used in the underground distribution of electricity.** William Geipel, 112, Belvedere road, Lambeth.

SPECIFICATIONS PUBLISHED.

1890.

14181. **Electrical fog signals.** Andrews. (Second edition.)

1891.

20413. **Electrolytic apparatus for making caustic soda, etc.** Bamberg.

22255. **Electric telephone transmitters.** Swinton.

22265. **Telephony and telegraphy.** Stephen and Davis.

1892.

1096. **Electric signalling on trains.** Shiels.

1024. **Electric switch.** Crompton.

5654. **Dynamo-electric machines.** Reignier.

8493. **Telephone transmitter.** Whitehead.

14785. **Electric despatch system.** Bryson.

15000. **Electrical circuits and cables.** Newton. Barrett.

16794. **Signal telegraphy.** Roughton.

17224. **Electrically heating and working metal.** Thompson. Coffin.

18116. **Electric arc lamps.** Mathiesen.

NOTES.

Burnley.—Tenders are wanted for fitting the Burnley Town Hall with electric light.

Electric Heaters are being tried experimentally on several electric street railroads in New England.

London World's Fair.—A World's Fair for London in 1895 is proposed, and an executive has been appointed.

Turbines.—A double turbine, with compensated pivot, by Messrs. Escher, Wyss, and Co., of Zurich, is described and illustrated in the *Revue Industrielle* (December 10).

An Electrical Minister.—It is rumoured that Mr. Henry Villard, whose name is identified in America with electric traction interests, is to be appointed United States Minister to the Court of Berlin.

Chicago Catalogue.—The Royal Commission for the Chicago Exhibition are arranging for a series of introductions to the sections of the catalogue of the British section. That on "Electricity" will be by Mr. W. H. Preece, F.R.S.

Children's Lectures.—Electricity and its marvels will be the theme of Prof. Lodge's four addresses, to be given with experiments on four successive days next week, beginning on Tuesday, at the University College, Liverpool.

Popular Electrical Science.—The *Scotsman* is setting a worthy example to the large provincial dailies in giving a series of admirable articles, by an experienced hand, on "Electric Lighting." The second of these, on "Distribution," appeared in last Saturday's issue.

The Liverpool Overhead Railway.—The Marquis of Salisbury has accepted the invitation of the directors to open the overhead railway on Saturday, February 4. His lordship will arrive in Liverpool on the previous day, and will be the guest of the chairman, Sir William B. Forwood, at Blundellsands.

Technical Index.—We have received the "Fortschritte der Elektrotechnik" for 1891, second part, from Mr. Julius Springer, Berlin. This technical index to the advances in electrical science contains a classified list of articles in the journals, and a well-arranged set of paragraphs giving the salient points of progress of the past year.

Electric Lighting and Heating. — *L'Industrie Electrique*, No. 23, gives an elaborate description, with plans and sections, of the Grouvelle method of lighting and heating a private house from the same boiler plant. The arrangement seems very well thought out, and would be a useful one to adopt in many country houses.

Lecture on Edison.—A popular lecture was delivered last week at Leicester before the Debating Society and People's Institute on "Edison and his Inventions," by Mr. J. T. Gent. The lecture was well illustrated by limelight views. Mr. J. H. Parsons, who had charge of the lantern, also exhibited a miniature electric light installation.

Rubber.—The dearth of indiarubber has suggested to carriage builders who use rubber for their tires that a substance elastic, but not necessarily non-conducting, would do equally well for carriages, and leave more raw material for electrical and other purposes. The invention of such an artificial rubber should, therefore, prove profitable.

Western Electric Company.—This company sends us a handsome calendar, the principal feature, however, of which, is an excellent photograph of their exhibits at the late exhibition at the Crystal Palace. This is one of the best photographs of any exhibit we have ever seen, and as our readers know, we looked upon this exhibit as one of the best, if not the best, telephonic exhibit at the Palace.

Text-Books.—A second edition of the very comprehensive "Handbuch der Elektrotechnik," by Dr. Erasmus Kittler, has just appeared from the publishing house of Ferdinand Enk, of Stuttgart. The work is to be complete in three volumes, price 40 marks, with 675 woodcuts in the text. The same firm issues shortly a students' text-book by Dr. J. G. Wallenstein, 253 illustrations, price 12 marks.

Dublin.—The Irish capital is not behind in electric traction, and the jaunting car must give way to the trolley car. So, at least, the signs seem to point out, for the Dublin Southern District Tramway Company are applying for powers to use electricity on their lines to vary the present system. These lines they intend to double, using electric cars, as well as building new lines. The City Fathers meet to consider this important question on January 16.

Acid Measurement.—MM. Colette and Demichel, in the Exposition d'Alcool, in the Champs de Mars, Paris, showed a useful instrument for measuring electrically the exact degree of acidity of any solution. Two plates are placed in a trough, through which the acidulated malt is passed, connected to a delicate ampere-meter, and the readings on this instrument are a correct indication of the state of acidity. An alarm bell is arranged to ring at either of the extreme allowable limits.

Rotary Fields.—M. E. Yorel, in *L'Electricien* for 17th inst., has a mathematical study of a rotary field created by a continuous current. Signor Ricardo Arno, of the Lincei Academy, has an article on rotary static fields, reproduced in the same number. He has experimented with cylinders of mica, ebonite, and other materials, and has produced a electrostatic rotary-field motor of 40 grammes weight, working with 3,800 volts at a frequency of 40, the motor rotating at 250 revolutions a minute.

Railway Telephones.—On one of the American railways, that between Port Defiance and Edison, telephonic communication is arranged to prevent delays in case of accident. Along the line a telephone wire is strung, and there are special poles, down which wires run to the height of a man above the ground. Each car carries a telephone, and in case of accident communication can be established at once with the main office, and in case of trouble details can be telephoned, and instructions for running the trains on either side can be given.

Ball Lightning.—The captain of the German steamer "Flandria" reports a curious instance of lightning on March 6, 1892, in latitude 38deg. north and longitude 41deg. west. In the midst of a violent tempest a luminous ball, like a huge star, appeared in the midst of the blackened clouds, grew to a maximum, and then burst, followed by long rolls of thunder. Flashes of lightning spread in every direction, giving an intense light that blinded everyone for some minutes. This phenomenon was observed twice, the duration being about five seconds.

Electro-Culture. — Considerable interest is being aroused in scientific circles in this city, says the *Bristol Times*, in a lecture which Dr. E. H. Cook is to deliver on the above subject on Monday next, in the lecture theatre of the museum. Dr. Cook has been experimenting for several years in this field, and, besides giving a history of what is at present known on the subject, will describe and illustrate some of his own experiments. These have not been hitherto published. The lecture is under the auspices of the Literary and Philosophical Club, 28, Berkeley-square.

Car Fenders.—The question of fenders, or safety guards, for electric cars is exercising the minds of the tramway engineers and city authorities of Boston, U.S., to a very active degree. Several fatal accidents to children

caused the authorities to insist on the use of more effective guards, and the company offered to put on any that the city council recommended. This has thrown the responsibility on the city, and a committee are still considering the question. Meanwhile, the West End Railway Company themselves are doing their best to discover an absolutely safe guard.

Institution of Mining and Metallurgy.—The third ordinary meeting of the second session of this institution was held on the evening of Wednesday, December 21, in the lecture theatre of the Geological Museum, Jermyn-street, S.W. (the use of which was kindly granted by the Lords of the Committee of Council on Education). A discussion took place on the paper by Mr. A. G. Charleton, A.R.S.M., M.Amer.Inst.M.E., etc. (member), on "The Industry of Mining," read on November 16; and a paper was read by Mr. C. G. Warnford Lock (hon. treasurer) on "Gold Amalgamation."

Alternating-Current Motors.—A cheap, practicable alternating current motor, of one or more horse-power, capable of starting and stopping at once under full load, is the desideratum for electrical engineers dealing with alternate currents. This motor has at last, we are assured, been successfully brought to perfection by an English manufacturer, and will be put on the market in the early part of the New Year. The results have been most satisfactory, and the professors will shortly have their turn in being able to theorise to their hearts' content on the action of the motor, and, more to the purpose, the companies will be able to utilise their day load by selling alternating current for motive power.

Steam Power from House Dust.—Our attention has been drawn by the Refuse Disposal Company, Salopian Wharf, Chelsea, who have lately published a pamphlet on the question, to the practical means by which the dust refuse of towns can be utilised for electric lighting purposes. The question has been greatly before the minds of electrical and borough engineers, and they might do well to obtain this publication dealing with an important municipal subject. The company claim that 20,000 tons of house dust, if treated as they suggest, and burnt in suitable boilers instead of destructors, might be made to produce as much as 5,600,000 indicated horse-power hours, equal to an engine of 1,183 i.h.p. working for 4,734 hours, for electric lighting.

Testing Insulation at Work.—With every well-regulated installation a voltmeter and ammeter are provided, conveniently fixed on the switchboard, to act as gauges for the electrical energy. For thorough safety we require as well an equally convenient means of testing the insulation of the installation at work, and this in any part—mains, dynamos, transformers—as easily as now any pressure can be tested on the voltmeter. The French Society for Encouragement of Sciences offers a prize of 2,000f (£80) for the description of the best method of achieving this result, and as several electrical engineers have been turning their attention to this point, the prospect of reward and honour may stimulate them to compete. The award takes place early next year, and papers must be sent in at once—before January 1.

Trolley Wheels.—The *Electrical World* comments on the adoption of the trolley conductor electric tramway at Walsall with a sort of amused smile at thoughts that the American system could be "improved," but at the same time hoping that it will be a success both for the sake of the railway and for their own—"as it certainly is an improvement from the æsthetic standpoint which we would be glad to introduce, if practical." Advice is given to the Walsall engineers that they should have their men well up in the art of replacing the trolley wheel after it has jumped off, as American ones are generally inclined to do when going at some speed. The question is asked: "Why 350 volts?"—if by English law, then is compassion expressed for those who pay the bills; but as 500 volts is the standard in America, "why should the English engineer want to go over the same ground again?"

Telephoning Sermons.—An interesting experiment in long distance telephoning was tried at the residence of the editor of the *Yorkshire Post* at Leeds, on Sunday evening, in the presence of a small party of friends. For about two years Christ Church, Birmingham, has been fitted with telephonic transmitters. On a few occasions the effect has been tried in towns at a distance of 50 [illegible] miles, and, as a rule, the service has been successfully transmitted. No attempt had yet been made until Sunday night to cover so great a distance—130 miles—as that involved in the connection between Birmingham and Leeds, which had to be established *viâ* Manchester. The service had in this case to pass through three exchanges—those of the three towns named—before it reached the party of listeners, who were furnished with a number of single receivers. The experiment was fairly satisfactory.

Electric Furnace.—M. Moissan has succeeded in obtaining a temperature of 3,000deg. C. with an electric furnace of lime bricks, using high-tension currents, the highest temperature obtained previously in the oxygen furnace of Deville and Debray being about 2,000deg. C. Near 2,500deg. C., M. Moissan found that lime, strontia, and magnesia crystallised in a few minutes. If the temperature rises to 3,500deg. C., the walls of the furnace melt. With the current of 50 h.p. the exterior of the furnace becomes red hot in a few minutes. Crystallisation of precious stones, such as rubies, have been obtained. The greatest precautions have to be taken in these experiments, both on account of the high potential, the great heat, and also for the effect on the eyes of the operator. The *Bulletin Internationale* states that another experimenter has made a number of similar experiments, and will shortly publish a paper on the subject.

Explosions.—Prof. A. Witz, of Lille, in a long study on boiler explosions (given in the *Comptes Rendus*) thus sums up his conclusions: "The greater number of explosions are due either to an original defect in the construction of the boilers, or to a state of decay, fatigue, or wear; it is, therefore, easy to reduce to a small fraction the chance of accident. A boiler well thought out in general form, well designed in details, constructed of good material according to the best practice, provided with proper safety apparatus, fed with properly-purified water (not muddy, greasy, or corrosive), not overloaded, inspected regularly, and conscientiously worked by an intelligent, sober, zealous and honest stoker, is, so to speak, inexplosible." He estimates the chances of explosion as 1 in 10,000, and of grave accident 1 in 20,000. This should reassure users of steam power, but not inspire them with a culpable negligence, which could only produce a false security.

Dangers of the Telephone.—The *Lancet* calls attention in a note to the latest outcome of competitive civilisation in the "telephone ear," which was foreseen and described by Prof. Lannois, of the Lyons Medical School. For ears which are not specially sound he considers the telephone contra-indicated, as even in a comparatively robust organ its continuous use is followed by symptoms more or less grave—cephalalgia, vertigo, hyperæsthesia, insomnia, and sometimes psychical disturbances of a character which might become chronic. He counsels a sparing use of the instrument in the case of those whose ears are sound and an absolute abstention from it in those

whose organs are already impaired from causes hereditary or induced. His memoir, which was read and discussed in a confirmatory sense at the Congress of Aural Surgeons held in Paris in 1889, will be found in the "Comptes Rendus et Mémoires," p. 265, for the same year.

Lighting Large Buildings. — Mr. T. Crichton Fulton delivered a lecture last week before the Edinburgh Architectural Association on the "Electric Lighting of Large Buildings." The lecturer explained the principles and practice of the electric lighting of buildings, and gave details of the arrangements employed and how they work. In describing various kinds of installations, he emphasised the importance of arranging the machinery, upon which everything depends, with plenty of space, light, and air so that it could be kept scrupulously clean. He described as typical installations a country house with water power, a factory in town with boiler power and a steam engine, and a large church with a gas engine for its prime motor. In speaking of the first case—the country house with water power—the lecturer pointed out the advantages to be derived from the use of turbines, and explained the use and importance of storage batteries in such a case. In concluding, he dwelt strongly on the propriety of having all work properly designed from the beginning, and thoroughly inspected and tested whilst in progress. A cordial vote of thanks was passed to Mr. Fulton for his lecture.

House Lighting.—The electric mains come to a man's door, his wife urges him to have the light, he thinks it over, finds out the price, looks and longs, and finally orders. Often, if intelligent, he buys a book "about the electric light" first. At any rate, if he finds one on a bookstall he pays his shilling, and perhaps gets what he wants. More probably he still is left in wonder at electricity, but if the book is a good one he learns something definite about the light, and is content. Mr. Angelo Fahie has written such a book for purchasers—"House Lighting by Electricity" (Spon and Co.)—short, clear, and practical, with explanations of principles and terms, illustrations of lighting and heating apparatus, as well as motors, and, what the purchaser will desire, a set of estimates. In the explanation it is doubtful if labelling the electric action "induction" without other explanation will clear the householders' ideas on "transformers," and the theory of the dynamo naturally cannot be very fully given in a page. Nevertheless, a good deal of practical information is given in the 80 pages of the work. One could have wished to have seen it without the very modern Venus cover.

Electro-Metallurgy.—Mr. J. W. Swan delivered a lecture on "Electro-Metallurgy" last week before the Newcastle Literary and Philosophical Society, dealing with the history of the industry and illustrated with numerous interesting experiments. He referred at the conclusion to the College of Science in that town, for which money was yet needed. When the college scheme was fully carried out, as he trusted it would be at no distant date, Newcastle would possess a technical teaching institution second to none in the kingdom in point of appliances and efficiency—an institution entirely worthy of the position and reputation of the town as a centre of manufacturing industry, and a most effective instrument in maintaining and extending its prosperity. The experiments shown at the lecture were greatly appreciated, especially that of the welding on the table, and before everyone's eyes, of pieces of metal by the electric arc, performed personally by Mr. Unwin. The performing of this practically in a lecture hall is a work of some difficulty. The electric energy was supplied by Messrs. Holmes and Co., of Newcastle. The light evolved was so intense that the operation had to be witnessed through screens of ruby glass. Cordial votes of thanks were given to the lecturer and chairman.

Crystal Palace School of Engineering.—Last Saturday afternoon the certificates awarded by the examiners for the winter term to students attending the Crystal Palace Company's School of Practical Engineering were distributed by Mr. W. H. White, C.B., the assistant controller and director of naval construction of the Admiralty. The examiners, Messrs. A. G. Drury, C.E., Thomas Inman, C.E., and J. G. W. Aldridge, C.E., who inspected the mechanical, the civil engineering, and electrical sections of the school respectively, reported that the number of students who had attended the lectures during the term was 58, of whom 39 had satisfactorily passed, and that the work done in the different departments was of a very creditable character. In an address to the students, Mr. White took the nobleness of the profession of engineering as his text. He thought they might, without any accusation of undue claims, say that engineering was a profession—nay, that it was a learned profession in these days. If a man was to hold his own in any branch of engineering, he required to be as studious and as well informed in his own subjects as any man could be in any branch of learning whatever. And, even as regards range of subjects, he maintained that neither the clergyman, the doctor, nor the lawyer had greater demands made upon him than had the engineer. The certificates were then presented to the students. Mr. J. W. Wilson, C.E., principal of the school, also spoke, and a vote of thanks was passed to Mr. White.

The Deri Electromotor.—Herr Déri, the well-known Hungarian electrical engineer, has been working at the problem of constructing a direct-current motor without self-induction. In *Electricité* (December 15), M. F. Guilbert gives some account of the new Déri motor recently patented, and illustrates the windings and the curves, of effective E.M.F. of the machine. Several different methods of winding are employed, the same in general principle. The coils on the armature core are wound so that the end of each circuit is connected to the commutator segments diametrically opposite. The extremities of each circuit come simultaneously into contact with the two brushes which lead in the current. The brushes are made large enough to touch several commutator bars, which puts the coils out of action in short circuit. In order to reduce the air gap, the coils are disposed symmetrically, and the arrangement can be used identical with the Gramme ring, but connected as described. Another method of winding is also used. The principle is the same, but each circuit has the direction of winding changed, equally spaced, and in number double that of the poles of the field magnets—for a two-pole motor, four inversions. Other arrangements are suggested. The fact that during rotation each circuit is only traversed momentarily by the current allows the current in the armature to be very much greater than in the armature of an ordinary motor, while allowing the same heating and same loss of energy. The exact action of induction due to fields and due to rotation of armature are investigated by Herr Déri. The motor is easily regulated to any speed by adjusting the brushes.

The Inventors of the Telegraph.—Prof. Thomas Gray, of Terre Haute, Ind., celebrates the beginning of the second century of the American patent system by an address on the "Inventors of the Telegraph and Telephone," giving in succinct form the history of these inventions. From the discovery of Stephen Gray in 1729 that electrical influence could be conveyed to a distance by insulated wire, of Romagnosi in 1805 of the deflection of a needle, rediscovered by Oersted, to the inventions of

Schweigger, and Schilling, and Steinheil, up to Morse, the gradual evolution of the telegraph is traced. The influence of the researches of Prof. Henry receives adequate recognition in this paper, and his claims are quoted: "(1) Previous to my investigations, the means of developing magnetism in soft iron were imperfectly understood, and the electromagnet which then existed was inapplicable to the transmission of power to a distance. (2) I was the first to prove, by actual experiment, that in order to develop magnetic power at a distance a galvanic battery of 'intensity' must be employed to project the current through the long conductor, and that a magnet surrounded by many turns of one long wire must be used to receive this current. (3) I was the first to actually magnetise a piece of soft iron at a distance, and to call attention to the fact of the application of my experiments to the telegraph. (4) I was the first to actually sound a bell at a distance by means of the electromagnet. (5) The principles I had developed were applied by Dr. Gale to render Morse's machine effective at a distance." Which is the better-known name, asks Prof. Gray, that of Henry or Morse? and he pertinently adds, "Would not Henry have gained both in popularity and in scientific reputation if he had patented and made the public pay liberally for his discoveries?"

Electricity in Agriculture.—A series of articles, which should have good effect in spreading the use of electric motors, is being given in the *Electrical World*, entitled "Applications of Electricity to Agricultural Work." The importance that electricity is likely to exercise in agricultural operations is hardly yet realised, even in America. Such articles ought to be copied and widely published in the daily journals, for they contain much that the public is waiting for. With exhibitions on the one hand for occular demonstration and with descriptive articles on the other—so that the various arrangements may be thought over and settled by the intending customer—there certainly should be an ever-extending field for motor application in homestead and agricultural work. A bit of a stream somewhere near (providing it has a fall), with a small turbine and dynamo should supply, besides lights, the motors for washing, churning, milk separating, cider presses, as well as, perhaps, heat for ironing, baking, and what not. We suggested a little while ago that it would pay the electrical engineer to study house-warming, pumping, and dairy requirements, and make these arrangements part of his profession. After all, what is it that is wanted but the "application of natural forces to the needs of mankind"? Light is but one out of many of these needs. The organisation of life requires codification—reduction to a well-understood plan, and the means of doing this in an ideal manner lies in the hands of the electrical engineer. It will be well for him to pay attention to these matters from the point of view taken in the articles above mentioned, and do his best to extend the knowledge of the applications of electricity to useful everyday life. One well advertised example, which could be visited easily, of a thorough and complete homestead installation, where everything was done by electricity from top to bottom, would be far more effective to the general public than many exhibits of single applications. Business would not be wanting to men who laid themselves out in this manner to satisfy the whole demands of enquiring proprietors.

A Universal Transformer.—Signor Giulio M. Appolonj, of Rome, describes in the *Electrical World* for December 10 what is termed a universal transformer, in three types of the same general design but of modified detail, according as they are required (1) to transform a continuous current of one pressure into a continuous of another pressure; (2) a simple alternating current into a continuous current, or *vice versâ*; (3) a polyphase current into a continuous current, or *vice versâ*. The apparatus is ingenious, and theoretically interesting, though no figures or results are given. Imagine a heavy ring core built up of iron discs in the usual way. In the body of each disc are stamped out eight square holes, so that the resultant ring core has eight apertures through its substance. Through an aperture wind copper windings, passing over and over to the outer edge of the ring, then from the coil so made pass to the next aperture in series, and so round the whole eight apertures. This constitutes, say, the primary circuit. Now, with the same apertures wind secondary coils passing to the inner edge of the ring, first in one aperture, then passing to the next aperture in series, and so on for the whole number. It must be realised that this arrangement gives two Pacinotti rings rigidly connected together. Add two commutators and make the two sets of brushes revolve, and the result will be that if a continuous current is sent in at one pair of brushes a continuous current will come out of the other pair, the potential being, of course, dependent upon the size of the wires. So far the continuous-current transformer. It can easily be seen that for the second type, to convert continuous into alternating, or *vice versâ*, all that is necessary is to omit one of the commutators. The second type, therefore, has a Pacinotti ring inside with commutator and a set of wires on the exterior half of the ring, simply arranged to produce four poles corresponding to those produced internally when the current is introduced. The one set of brushes leading in continuous currents is made to revolve, and produces in the other circuit an alternating current, of high or low potential according to the winding. As the apparatus is reversible, it follows that we should have the simple apparatus so long desired of at once transforming any alternating current to a continuous current of any desired potential. The third type, the polyphase transformer, has six apertures only, with three coming in wires: for the exterior circuit attached at an angular distance of 120deg. from each other. If a continuous current is sent through the revolving brushes, three alternating currents will be produced in the outside circuits, displaced 120deg.; and *vice versâ*, if such polyphase currents are sent into these three wires, the revolving brushes will draw off continuous currents. With these three types it is claimed any transformation of current can be obtained, coupled with redressing—continuous, alternating, or multiphase. These advantages are obvious. There are besides several essential advantages. In the first place, there are no heavy pieces in motion—the brushes can be moved by an insignificant fraction of a horse-power; in the second place, the transformer is not costly. It is especially suitable for charging accumulators in transmission of power at high potential by continuous currents. The second type is adapted for alternating-current systems, for charging accumulators, and for electric traction. So far, no electric railway has been run by alternating currents, as synchronous motors are impracticable for traction. With the above apparatus this is claimed possible, because it allows of redressing into continuous current, accompanied by a lowering of the voltage. In the case of long railways this might be done on the locomotive itself, while for ordinary tramways the transformers could feed into the trolley mains. For the transmission of power these transformers would permit the use of continuous current motors on alternating current circuits. The practical questions that present themselves are: what about sparking and the lag effect of varying the load? It would be interesting to have the result of tests.

FIELD MAGNETS.

BY GISBERT KAPP, M.I.C.E.

(Continued from page 611.)

Multipolar Fields.—An example of a multipolar field has already been given in Fig. 2. This is the double four-pole magnet used by the Brush Company in their "Victoria" dynamo. The armature is a ring of large diameter as compared to its length, and the poles are presented to the end faces from either side. We require thus eight magnet cores with their axes parallel to the spindle, four on either side. The outer ends of the cores are joined by two massive cast-iron yokes. Fields of this type are frequently used in alternators.

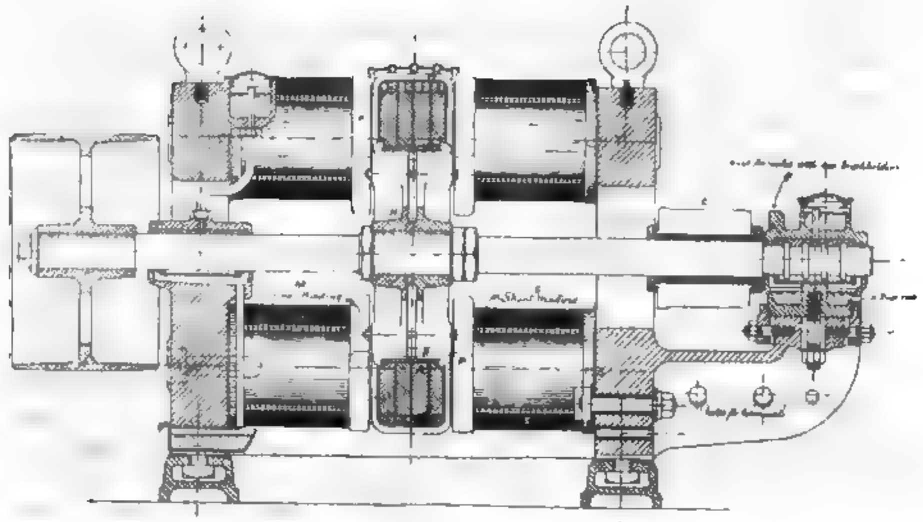

FIG. 2.

In machines with cylindrical armatures (whether dynamos or alternators) the pole-pieces are necessarily parts of a cylindrical surface, and the axes of the magnet cores are generally at right angles to the spindle. Any multipolar field may be considered as a combination of

FIG. 58.

bi-polar fields. Thus, by taking two fields of the type 57c, we can produce a four-pole field of the type 58. In a similar way Fig. 59 may be considered to result from Fig. 57e if we increase the curvature of the yoke so as to get room

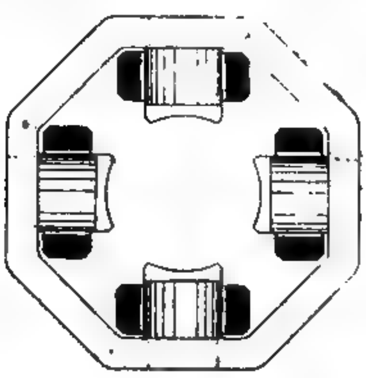

FIG. 59.

for another pair of magnets. The coupling up of the coils must in this case be reversed, so that diametrically opposed poles have the same, and neighbouring poles the opposite sign. By duplicating Fig. 57f, we obtain the field shown in Fig. 60. In this design four poles are produced by the use of only two exciting coils. Fig. 61 may be considered to result from the combination of four fields of the type shown in Fig. 57a. If a field of more than four poles be required, we may produce it by combining three or more fields of the 57c type; but this presents considerable mechanical difficulties in supporting the magnets, and is also, for other reasons, less advantageous than an expansion of the arrangement, Fig. 59, which is shown in Fig. 62 as applied to a 10-pole machine. Fig. 61 may also be expanded into a field of six, eight, or more poles, and is with continental makers a favourite type. Another type exclusively used on the Continent is the reverse of Fig. 59, the poles being placed inside the armature, which must in this case be overhung, the active conductors being on the inside. Fig. 63 shows a 10-pole field of this kind. To give an idea of the relative weight of armature in Figs. 62 and 63, the outlines of the armature core have been inserted in the diagrams, which represent machines of equal output and equal speed. The field of Fig. 63 is about half the weight of Fig. 62, but this advantage is bought at the cost of a more difficult mechanical construction, both as regards the support of the armature core and the positive driving of the armature conductors.

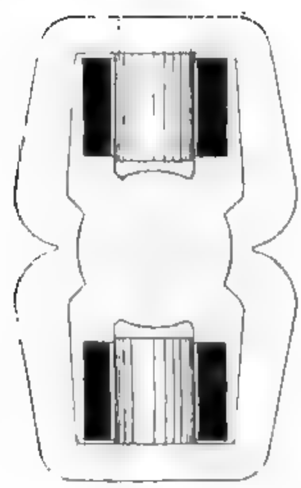

FIG. 60.

There is no hard-and-fast rule by which we can judge the merit or otherwise of any of these types of field. The voltage, size, and speed of the machine, the greater or lesser importance of small weight, the possibility of obtaining soft steel castings, the relative cost of copper and iron, the energy permitted for excitation, the temperature rise allowed, and, last, but not least, the skill of the designer, are all items on which the value of any type depends; but, as a general guide, a few facts may here be usefully stated. If pole-plates are used with Fig. 58, whereby it is possible to make the section of magnets not too much different from a square,

or if the armature is fairly short, whereby the magnet's section naturally approaches a square, the amount of exciting wire required is not excessive, and the total weight of field is very moderate. As far as iron and copper are concerned, this type of field is fairly cheap, but the mechanical support of the magnets is somewhat expensive because it must be formed entirely of gunmetal brackets or chairs. Another drawback is that there is little ventilation for the armature and less for the inside of the field coils, so that

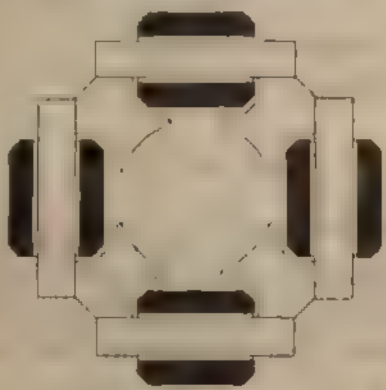

Fig. 61.

the heating will be greater than in machines of less compact design. Fig. 59 requires the same amount of magnet wire or possibly a little less than Fig. 58, but the whole field is much heavier if the yoke be made of cast iron. If the yoke be made of soft cast steel it need only be from one half to one third the section of the cast iron yoke, and then Fig. 59 becomes lighter than Fig. 58. There is the further advantage that no gunmetal supports are required, the field being of the iron clad type. The whole design is more open than Fig 58, and the ventilation of armature and magnet coils is better.

Fig 60 is a very simple design and requires about the same amount of copper as Figs. 58 and 59; it is, however, very heavy if cast iron be used for the yoke. With cast steel the weight may be brought down to less than either of the previous designs, especially in small machines. The fact of the armature and field coils being protected by the surrounding yoke renders

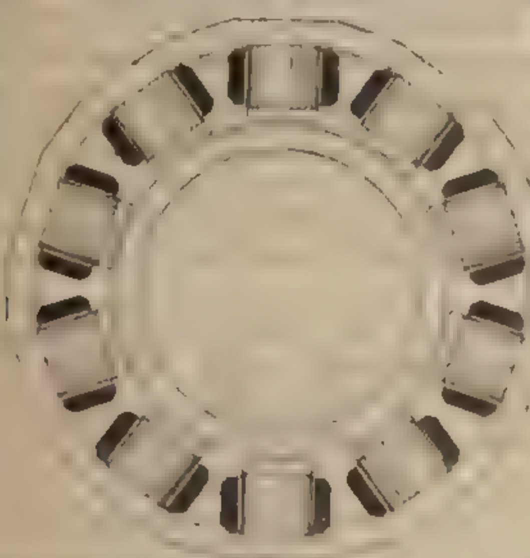

Fig. 62.

this design suitable for machines which are exposed to rough usage, such as tramway motors. Machines of this type have also been used for shiplighting, where an iron-clad field has the advantage of not disturbing the compasses. The field shown in Fig 61 is heavy and expensive. It requires gunmetal supports and rather more wire than Fig 58, but the cooling surface of the coils is large and the ventilation very good. This type is used for 10 and more poles in the newest design of Edison central station machines, and an example is also furnished by the new generator of 300 kilowatts (2,400 amperes at 125 volts) used for the distribution of electrical energy for motive power throughout a small-arms factory near Liége.* In this machine, which is more remarkable for its dimensions than its output, the armature is 15ft. 9in diameter, and the field has 20 poles. The magnet cores and poles are of soft cast steel and weigh 10 tons, whilst two

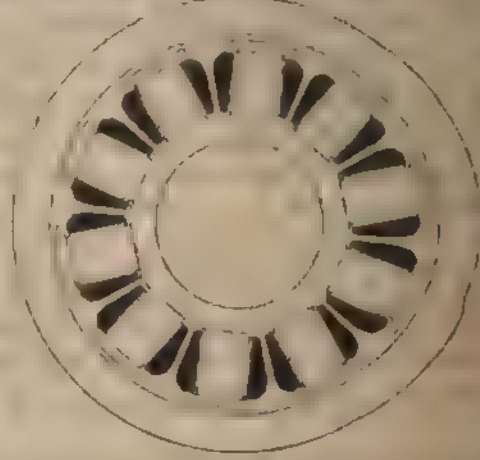

Fig. 63.

tons of exciting wire are used. The speed of the machine (which is direct driven by a Van der Kerchove engine) is 166 revolutions per minute, giving the armature the remarkably high peripheral speed of over 8,000ft per minute. At this speed the weight of field is about 90lb per kilowatt output. In machines of the type, Fig. 58, the weight of field is under 100lb per kilowatt for a peripheral speed of armature of 2,000ft per minute. This is three and a half times better than the condition of the Liege machine the field of which is of the type shown in Fig. 61, but expanded to 20 poles.

Weight of Fields.—A rough comparison of the different types of field as regards their weight has been made above, but in order to bring this important matter more clearly into view, it appeared to me desirable to give the reader some examples actually worked out so that he could compare figures rather than mere general statements. The figures given refer, of course, only to the particular cases

Fig. 64.

selected, and their relative value would come out differently if we made the designs for a larger or smaller output, or a different speed or different armatures. In order to get representative figures it was, therefore, necessary to select

Fig. 65.

fairly representative cases, and I have chosen for two-pole machines an output of 25 kilowatts, at 550 revolutions, as being about midway in the range of output and speed for which two-pole machines would usually be adopted. The armatures are 12in diameter by 15in long, and have, therefore, a peripheral speed of 1,730ft. In two cases the armatures are 15in by 15in, and have a peripheral speed of 2,160ft. For the fields having four poles I have chosen an output of 80 kilowatts, at a speed of 500 revolutions, as being fair average conditions for which four-pole

* L'Electricien, vol iv., No 39, p 177, September [illegible] 1892.

machines would be employed. The armatures are in all cases 24in. diameter by 20in. long, and have a peripheral speed of 2,380ft.

Before giving the results of this investigation it is necessary to say a few words on the methods employed in designing the fields. The laws which govern the amount of exciting power or ampere-turns for any given configuration of magnets will be found below in this and the next chapter. For the present it is only necessary to state that these laws have been followed in determining the amount of field wire required, and that due regard has been paid to armature reaction, heating limit, and percentage of exciting energy. Where advisable, pole-horns or pole-plates have been added to reduce exciting power or length of wire; and in two cases (Figs. 64 and 65) the poles have been cut so as to reduce armature reaction and permit the use of a lighter field. The armature in these two cases has been increased to 15in., and is, of course, heavier and more expensive than the 12in. armature, which is used throughout the other two-pole fields. In all the two-pole machines the armature is designed for a copper loss of $3\frac{3}{4}$ per cent. Precisely the same armature (24in. diameter by 20in. long) is used in all the four pole fields, and it has been designed for a copper loss of $2\frac{1}{2}$ per cent.

As regards the copper loss in the fields this has been limited to $3\frac{1}{2}$ per cent. in the two pole and to 2 per cent. in the four-pole fields, except in those cases where the heating limit made it desirable to work with a smaller expenditure of power in the field. The temperature rise has been determined in every case, and will be found in the table below. The weights given are simply for the iron in the magnetic circuit and for the copper wire, but do not include the weight of any formers, terminals, chairs, and support for the magnets. For convenience of comparison I have added the weight of magnets per kilowatt output, on the supposition that the peripheral speed of the armature is in all cases 2,000ft. per minute. The magnet cores are in all cases of wrought iron; the poles are of cast iron in 57a, 57b, and 64. The yokes are of cast iron in 57c, 57e, 57f, 59, and 60.

Field Magnets for Two-Pole Machines.—25 kilowatts output, 650 revolutions.

Type of Field. Fig.	57a.	57b.	57c.	57d.	57e.	57f.	64.	65.
Total weight of field, lbs.	5,090	4,670	3,020	2,790	6,750	5 070	3,670	2 400

Weight of field in lbs. per kilowatt output at 2,000 feet peripheral armature speed	90	147	163	109

Determination of Exciting Power.—The law which governs the production of magnetic flux by the application of a certain magnetic force has already been given, and it is by applying this law to special cases that we find the total exciting power measured in ampere-turns that is required to produce in dynamo magnets a definite flux, or total field. In what follows, the letter F will be used to denote the total flux in C.G.S. measure, and the letter Z will be used to denote the same quantity in English measure—or, $F = 6{,}000\ Z$. The exciting power in ampere-turns we denote by the letter X, so that the general equation (22) can also be written

$$X = F R \quad . \quad . \quad . \quad . \quad . \quad . \quad (33)$$

R being the magnetic resistance as defined in Chapter V., and being found by the formulæ:

$$\left.\begin{aligned} R &= \Sigma \frac{1}{1{\cdot}256} \frac{L}{A} \frac{1}{\mu} \\ \text{or, } R &= \Sigma \quad {\cdot}8 \quad \frac{L}{A} \frac{1}{\mu} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (23)$$

Or, in English measure,

$$X = Z R \quad . \quad . \quad . \quad . \quad . \quad (34)$$

where

$$R = \Sigma\, 1{,}880 \frac{L}{A} \frac{1}{\mu} \quad . \quad . \quad . \quad . \quad (25)$$

In this expression the length of the circuit, L, must be inserted in inches, and the area, A, in square inches; μ being merely a numeric, remains the same in both systems of measurement. In the special case that the part of the magnetic circuit under consideration contains only air or other non-magnetic substance μ becomes 1, and we have

$$R = {\cdot}8 \frac{L}{A} \qquad\qquad R = 1{,}880 \frac{L}{A},$$

since $F = \mathfrak{B}\ A$, and $Z = B\ A$, we find the ampere-turns required to produce the flux, F, in air by $X = \mathfrak{B}\ A \times {\cdot}8 \frac{L}{A}$

$$X = {\cdot}8\ \mathfrak{B}\ L \quad . \quad . \quad . \quad . \quad . \quad (35)$$

and similarly for English measure

$$X = 1{,}880\ B\ L \quad . \quad . \quad . \quad . \quad . \quad (36)$$

It is generally convenient to determine the exciting power separately for each part of the magnetic circuit, because the flux is not the same in all its parts. In a dynamo machine we have to distinguish between the flux through the armature, that through the air space (assumed to be the same), and that through the pole-pieces, joints, magnet cores, and yokes, which is always larger than the armature flux, because a certain proportion of the lines generated within the magnet coils never passes through the armature, but produce what is termed a leakage field through the air surrounding the exciting coils. Since leakage is simply a magnetic flux through air, and must follow the general law $F = \frac{X}{R}$, it will be seen that the amount of leakage must depend on the extent of the surfaces which are under different magnetic potentials, their distance apart, and on the difference of magnetic potential or magnetomotive force. Generally speaking, the leakage will be the greater, the greater the exciting power the larger the external surfaces of pole-pieces, and the less the distance between poles of opposite sign or between poles and yokes.

The magnetic resistance of joints is generally neglected, and in well-made machines, where the joints are properly faced and strongly pressed together mechanically, their resistance is quite insignificant compared to that of other parts of the circuit. Prof. Ewing* has experimentally investigated the magnetic resistance of joints by observing the decrease of induction with the same magnetising power in a bar which had been successively cut into two, four, and eight pieces. He found that by applying mechanical pressure to the joints their resistance was diminished, and since in a well-made machine the joints are either strongly bolted up or are a good driving fit, we may take it that the necessary mechanical pressure for a good magnetic fit is obtained. Ewing gives the resistance of the joint in comparison with an equivalent layer of air between the surfaces. For $H = 30$, and $\mathfrak{B}$ varying from 14,550 to 9,800, the equivalent layer of air is ·002 centimetre thick. For $H = 50$, and $\mathfrak{B}$ varying from 15,950 to 13,300, it is ·0013 centimetre thick, and for $H = 70$, and $\mathfrak{B}$ varying from 16,820 to 15,200, it is ·0009 centimetre thick. If we calculate from Ewing's figures what exciting power is

* *Phil. Mag.*, Sept., 1888.

required to overcome in each case the resistance of the joint, we come to the remarkable result that with an increasing induction the exciting power actually diminishes. We find for

$$\mathfrak{B} = 12{,}175 \left\{ \begin{array}{c}\text{ampere-turns required to overcome} \\ \text{resistance of joint}\end{array} \right\} = 19{\cdot}6$$

$$\mathfrak{B} = 14{,}625 \quad \text{,,} \quad \text{,,} \quad \text{,,} \quad = 17$$

$$\mathfrak{B} = 16{,}020 \quad \text{,,} \quad \text{,,} \quad \text{,,} \quad = 11{\cdot}6$$

This result may possibly be due to the fact that with the greater induction the magnetic attraction is also increased, and thus the contact of the joints in Ewing's experiments may have become better as $\mathfrak{B}$ became larger. The conditions of the experiment were, therefore, not exactly those obtaining in a system of heavy field magnets, where the joints are in any case under great mechanical pressure. For the rest it is a matter of indifference whether we allow 10, or 50, or 100 ampere-turns for the resistance of each joint, because the total exciting power is reckoned not by tens, but by thousands of ampere-turns, and we are thus justified in entirely neglecting the resistance.

There remain thus only three parts of the magnetic circuit to be separately dealt with—namely, armature, air spaces, and magnets—including poles, cores, and yoke. To find the total exciting power we have merely to determine separately the exciting power, X_a, required to drive the flux through the armature, that required for the air space (which we call X_α), that required for the magnet cores and poles (X_m), and that required for the yoke (X_y). We shall use the same indices, a, α, m, y for F or Z, and $\mathfrak{B}$ or B to distinguish respectively the flux and induction through the various parts of the circuit. The following symbols will also be used:

L_a = average length of path of lines through armature core;

δ = length of air gap or interpolar space;

A_a = net area occupied by iron in armature core;

A_α = area of air gap;

A_m = cross-sectional area of magnet cores;

A_y = cross-sectional area of yoke;

L_m and L_y = length of paths through magnets and yoke respectively.

(To be continued.)

VESTRY OF ST. PANCRAS.

[The report on the introduction of electric lighting has just been issued, signed by Mr. T. Eccleston Gibb. The first portion is historical, showing how St. Pancras came to deal with the matter. Below we give the latter part of the report, containing all the figures relating to the cost and to the working, figures of the utmost importance at the present time when so many municipalities are concerning themselves with this question.—Ed. *E. E.*]

The works required were advertised for to be carried out under seven contracts, and were let as follows: No. 1, buildings, Kirk and Randall; No. 2, boilers, Babcock and Wilcox, Limited; No. 3, engines, dynamos, etc., Willans and Robinson, Limited; No. 4, switchboards, The Electric Construction Corporation, Limited; No. 5, batteries, The Electric Construction Corporation, Limited; No. 6, trenches, Mowlem and Co.; No. 7, electrical conductors, Clark, Muirhead, and Co., Limited.

The following is a statement of the total cost of the installation, including the estimated cost of works not yet completed, and marked below with an asterisk:

Site.	£	s.	d.
Paid for freehold site, including houses in Longford-street reserved for extensions	10,000	0	0
Interest on purchase-money	21	7	5
Compensation for subsidiary interests and loss of rent	292	18	0
Law charges	169	5	10
Clearing the site	40	17	6
	£10,524	9	3

Obtaining Loans.			
Loan from the London County Council for £10,000	£29	15	5
Loan from the Prudential Assurance Company for £60,000	115	14	[illegible]
	£145	10	5
Station and Sub-Station.			
Buildings	7,906	2	[illegible]

Instruments, etc.	2,756	[illegible]	[illegible]
Public lighting	7,482	[illegible]	[illegible]
Miscellaneous	457	[illegible]	[illegible]
	£91,493	12	[illegible]

Some remarks are necessary with reference to a few of the items in the above statement:

(*a*) The land reserved for extension of works, and upon which the Longford-street houses stand, is capable of accommodating sufficient plant whereby the present output of current may be more than doubled.

(*b*) The total expenditure for street trenches and conductors, including the extensions in hand, is £34,894. 5s. 9[illegible] The original expenditure contemplated provision for current equal to 25,000 16 c.p. lamps and 90 arc lamps, although the machinery was designed for only 10,000 16-c.p. lamps and 90 arc lamps. This was necessary, as it could not be

* The three items marked *, amounting in the total to £[illegible], represent estimates for extensions, a large proportion of which [illegible] already completed and measured up. The whole of the works will, [illegible] doubt, be carried to completion for a sum less than the estimate [illegible] from £400 to £600.

† Mains not included.

foreseen where the current would be taken up. Since we commenced to supply it has been necessary to extend still further the original provision to meet demands in places not included in the scheduled area, so that now we have provision for more than 30,000 16-c.p. lamps, as well as the 90 arc lamps. The result of this is that at present nearly two-thirds of the capital expended on trenches and conductors, say, £20,000, is lying idle, and must continue to do so until further generating plant is put down at the station. The arc lamp plant will be fully charged as soon as the lamps now being erected are put in lighting, so that the arc lighting plant also must be extended before any* more public lighting can be undertaken.

(*c*) The amount expended for meters, switches, and fuses is £1,181. 13s. 8d. Of this sum about £1,000 is for meters, which are lent on hire, and which are a distinct source of revenue to the Vestry.

(*d*) The amount representing the value of general stores is large. Certain articles of stock, representing nearly half the total of £931. 10s. 4d., must be idle for the present, owing to a decision of the Board of Trade that the mains for public lighting should be kept distinct from those for private supply. This is not a dead loss, as the material can be utilised on further extensions.

(*e*) The extension of public lighting to King's Cross and The Brecknock will add but little to the expenses hitherto incurred for lighting Tottenham Court-road and part of Euston-road, as the plant which has had to be worked for a portion will be sufficient for the whole.

(*f*) The expenditure upon public lighting includes the cost of constructing the new street rests in Tottenham Court-road and other places where arc lamps have been erected. These rests are looked upon as a general public convenience, and might be considered a fair charge on the general rate.

(*g*) In the summary of receipts and expenditure, the amount shown as a temporary advance from the National Bank represents only that part of the total sum advanced by the bank, which is attributable to capital expenditure. The item of £7,303. 19s. 11d., the balance of the account, is not yet due, although the works are in hand, and it represents part of a larger sum upon which advances to the extent of £2,666. 0s. 1d. have been made. The advantage which the Vestry have had through obtaining this temporary accommodation from the bank, instead of obtaining a further loan earlier, is that only 3 per cent. interest has been paid upon the money instead of 3½ charged by the County Council and the Prudential Assurance Company, and there have been no instalments to pay off.

First Year's Working.

In giving particulars of the first year's working, it must be remembered that the officers and servants were appointed in September, and in one or two cases earlier, and that from that date the installation was worked for the purposes of testing, etc. There was other expenditure also for coal and other things, from which no remunerative return could be derived.

The following statement shows the working expenses from the commencement down to the 8th November, 1892, on which day the first year ended from the date the supply of current was commenced. Some of the expenditure therefore dates back for a year and a half, and even longer :

Coal	£2 306	15	2
Water, oil, waste, etc.	356	17	1
Salaries	689	6	11
Wages	2 301	17	4
Printing and stationery	187	7	10
Advertisements	35	3	9
Electrical papers for committee	18	16	10
Committee's expenses on view	20	0	10
Repairs	171	15	1
Insurance	79	12	9
Cost of meter connections (charged to consumers)	137	7	11
Licenses	19	11	5
Carbons for arc lighting	110	11	7
Other charges	119	1	1
	£6 552	5	7

* Two dynamos have been erected for the 90 arc lamps—one being kept as a stand-by in case of accident. If two more machines were erected, the one stand-by would still cover any risk, and 270 arc lamps could then be supplied. These 270 arc lamps would be sufficient to displace the whole of the 1,200 gas lamps within the area, which can be economically served from the present station.

Summary of Receipts and Expenditure on Working Account.

Receipts.	£	s.	d.
Current supplied from 9th November, 1891, to 30th September, 1892	4,691	2	5
Current supplied during October, 1892	1,023	5	2
Current supplied for eight days in November (estimated)	290	0	4
Current for public lighting	1,411	17	9
Current for public urinal	39	15	9
Works for private consumers—meter connections	148	15	4
Sundry small receipts	15	8	10
	£7,620	5	7

Expenditure.	£	s.	d.
As per statement above	6,552	5	7
Balance towards payment of interest and repayment of loans	1,068	0	0
	£7,620	5	7

With regard to the foregoing statements on the first year's working, I desire to make a few observations.

(*a*) It has been already pointed out that the expenditure is for more than a year. It may also be said that the expenditure has been upon a plant which for a large part of the time has not been doing a tithe of the work it was capable of doing. During last winter we had few customers, and during the summer but little light was required.

(*b*) In the above summary the receipts for current from the 9th November, 1891, to the 30th September, 1892, was only £4,691 3s. 5d., whereas during the month of October, when the plant was still not in full use, the receipts amounted to £1,023 5s. 2d. From this it may be expected that the total annual income from this source will be, without any extension of plant, etc., at least £10,000* a year, and this is exclusive of the value of current used for public lighting, which will add another £3,000 or so.

(*c*) With reference to the balance shown of receipts over expenditure of £1,068, it will be noticed that this is but a small contribution towards the amount charged for interest and instalments of principal. This point will be referred to in the cash statement later on. It may also be observed that nothing has been allowed for depreciation. The reason for this is that the six months' maintenance under the contracts has but recently expired, and some of the plant has been scarcely used as yet. No large provision for depreciation ever will be necessary, because electric lighting plant must be kept in perfect condition by continuous repairs and renewals in detail.

Cash Statement—Capital Account.

Receipts.	£	s.	d.
London County Council	10,000	0	0
Prudential Assurance Company	60,000	0	0
Rents	392	11	6
†Loan required to balance	21,854	3	4
	£92,246	14	10

Expenditure.	£	s.	d.
Preliminary expenses	753	2	4
Cost of installation and extensions in hand	91,493	12	6
	£92,246	14	10

Conclusion.

Having in view the absolute necessity for further expenditure to meet the constantly increasing demands for current and to put in use plant now lying idle, the Vestry should at once borrow a further £30,000, making the total capital for this installation £100,000. If only £21,854. 3s. 4d. is borrowed it will be sufficient to clear off the total indebtedness to the National Bank; but it will only leave about enough to recoup the £2,908. 5s. 7d. which has already been paid for interest and repayment of loan.

The expenditure made by the Vestry bears favourable comparison with the expenditure of the principal electric companies, and testifies to the zeal and ability which has

* This is a low estimate, as experience proves that each 16-c.p. lamp installed will yield an income of £1 per annum at 6d. per unit; and as 13 000 lamps installed represents in this district 10,000 simultaneously at work, the income may be expected to reach £13,000, or even more, per annum, and this without taking any account of the consumption for motive power during the times of light load.

† The actual sum due to the National Bank, as shown by the pass-book of the electricity department, is only £18,300. 1s. 11d., but the balance of £21,854. 3s. 4d. includes sums due, and to become due for extensions in hand, but not completed.

been exhibited by the committee and their advisers in carrying out this important work.

It will be necessary to construct before long two other installations, and I do not doubt that before many years are over the capital invested must reach half a million of money, but it is of no consequence what is spent if a good profit can be shown upon the outlay. The gas company receive from St. Pancras an income of about £50,000 a year, and the capital value of their property in the parish is estimated at about a million and a half sterling.

The cost of electricity, considering the relative amount of light, bears favourable comparison with the cost of gas, there is less risk from fire, and from the point of view of health and cleanliness, electricity is far superior to gas—a point of view which should be considered by the Vestry as the sanitary authority of the parish. In future the cost of electricity will no doubt be reduced through several causes in relation both to its production and distribution. Prof. Robinson reports that one very probable means of diminishing the cost of production will be by adopting a system of what he calls "thermal storage," by which the boilers are worked continuously, and the heat generated during periods of little or no demand is stored up in water heated to a high temperature at high pressure for utilisation at the times of maximum demand.

There is one source of profit that has not developed as rapidly as was expected—that is, the use of electricity for motive power. It is a subject to which the chairman of the committee, as is well known, has devoted much time and attention, and is one upon which I laid much stress in my report to the Vestry made in 1882—10 years ago. When recently it was determined to reduce the price of current for day supply, it was naturally expected that a considerable demand for motive power would arise; but it is to be regretted that, as yet, the advantages offered are not realised by the many small manufacturers to whom this would certainly be a boon. Recently, our resident engineer, Mr. Baron, has developed a suggestion of the chairman's for the provision of a "day switch," which it is hoped will give an impetus to the demand for power, as well as for lighting basements and places where the constant use of gas is injurious.

ECONOMIC POSSIBILITIES OF THE GENERATION OF E.M.F. IN THE COALFIELDS, AND ITS APPLICATION TO INDUSTRIAL CENTRES.*

BY B. H. THWAITE, C.E.

(Continued from page 616.)

The Metropolitan Scheme for the Transmission of Electrical Power generated in the South Yorkshire Coalfields. James Swinburne and B. H. Thwaite.

Description of the Electrical Portion.

Generating Station (see Fig. 1). The motive power will be supplied by 36 gas engines, each one capable of developing 300 b.h.p. It may be advisable at some future time to adopt larger power engines than these, but as we know that gas engines of this size can now be made, it is not requisite to discuss the desirability of employing larger sizes for the present. Larger engines will, however, cost less in proportion to power, be more economic, and will be superior in many ways, so it will be so much the better if we can adopt them instead.† The power will be converted by 18 alternating current generators, each of which will be coupled direct to two gas engines, so that there will be neither belts nor rope gearing. In order to secure a higher and more regular condition of speed than that of a 300 horse gas engine, both the armature and field magnets will revolve in opposite directions. The armature will be driven by one engine, and the field by the other.

The dynamo-electric generating machines will be separately excited by three direct constant current electric machines, coupled in series and driven direct by gas engines. Of these two will be able to excite the whole of the alternators, and the third will be ready as a spare one. The field magnets of the alternators will also be excited in series, so that their excitations, if it varies at all, varies simultaneously in all the machines. This will make it easier to secure a perfect condition of parallel running. In the daytime only one exciting dynamo will be run, and the other will be put into circuit as the load increases and more alternators are required. The independent adjustment of the excitation of the individual alternators will be effected by shunting the field magnets. This adjustment will be made once for all. The arrangement of the exciting circuits is to obviate the necessity of regulating the excitation which otherwise would arise when a cold machine is put in parallel with others whose fields have had time to become warm. The field magnets will not be wound with a single circuit in the usual way, but will have two circuits which are normally used in parallel. This allows the field magnets, which have a large self induction, to be coupled into the same exciting circuit without causing a spark when the switch in series to it is opened. On starting, one of the field circuits is short circuited on itself, and the exciting current is started in the other. It causes a momentary current in the closed circuit instead of making an arc at the switch. This dies away almost instantly, and the second circuit is then opened and put in parallel with the first.

The alternators will give 500 volts and 1,000 amperes each, as a lower pressure would make the switchboard cumbrous and expensive, and a dangerous tension is to be avoided in a station as far as possible. The alternating system will be designed for single currents, and both the armatures and fields will be laminated to secure perfect control, when the machines are in parallel, in spite of the throb of the gas engines.

The switchboard will have two omnibus bars and two single 1,000-ampere switches for each dynamo, and the gear for controlling the excitation and the high pressure circuits. To start a dynamo to the circuit the switches short circuiting its field are opened as already described; its field is then excited to the [illegible] extent, the engines are then run at the normal speed, and one of the switches is closed, so that there is one pole to one omnibus bar. The other switch is now closed through a resistance which permits a large enough current to bring the dynamo into step without any excessive strain. The second switch is then closed, and the machine is not only in parallel, but is taking its adequate share of the work. Each generator has a wattmeter on the switchboard, so that it can be seen at once if a generator is giving its correct output. The gas supplied to the whole of the engines will be regulated by a speed governor, or it may be regulated automatically by mechanism depending on the frequency of the alternating current, or by the hand of the man in charge. The gas for each engine will also be individually regulated. The engineer in charge can thus arrange what portion of the load is to be taken by each engine. This will in practice be settled once for all, as the valve gears of the engines will be so arranged that they take equal volumes of gas and do equal work, the whole of them being under the control of the main station governor. Each engine will have a speed governor as well, but it will be set at a speed above the normal to avoid any chance of running away under any circumstances. The E.M.F. of the station will be controlled by means of the exciting current, so that all the machines will be regulated together. The machine circuits will also have the usual double pole fuses. The omnibus bars will be connected to a bank of large transformers, which will raise the pressure to 30,000 volts. One third of these will be of the open circuit type, their exciting currents being supplied by the capacity current due to the long overhead conductors. The advantage of their higher [illegible] efficiency will thus be secured, and the complication due to the condenser action of the mains will be neutralised. The rest of the transformers, which will be in use for a few hours a day only, will be of the closed circuit type, designed for constant [illegible] loads. The transformers will be oil insulated, or the arrangement introduced by Mr. Kolben, of the Maschinen Fabrik Oerlikon, will be employed.

The transformers will have switches and double pole fuses on both circuits. In cutting a transformer out of circuit, the high pressure switches will first be opened. The fuses will also be arranged so that in case of any short circuit the high pressure circuit is first broken, so that there will be no 30,000 volt arc. The leads will be bare conductors carried overhead on poles. There will be three positive and three negative leads, an [illegible] pressure of 30,000 volts being used. The middle of the circuit will not be earthed at the stations, but electrostatic [illegible] will be arranged to alarm if the middle of the circuit varies from the potential of the earth. In the case of a partial earth on any conductor, that conductor will be instantly earthed [illegible] and cut out of circuit at both ends. The positive and negative wires will be arranged so as to be the same height. There will thus be no capacity currents induced which might affect telephone trunk lines.

The overhead conductors will be carried on creosoted wooden poles at a height of 30ft. from the ground at lowest point in summer. Oil insulators will be used. At short distances along the lines, lightning arresters will be arranged on the poles. The brackets for supporting the insulators will be metallically connected to earth by the lightning conductor on each post, so that if there were a leak at one insulator there would be no [illegible] potential along the post, which might be dangerous to anyone touching it. The upper pairs of wires will be arranged further apart than the lower, so that if one is fused by lightning or breaks it will fall clear of the others. The use of the upper pair of wires will be avoided as far as possible during thunderstorms, and [illegible] admit of this more readily they will be smaller than the lower. In addition to the power conductors, telephone wires will be carried on the same poles. There will also be a spare [illegible] wire for locating faults by the loop test. At intervals along the line there will be guard stations. There will be small [illegible] near the line, into which the telephone and testing [illegible] are led. A fault can be located much more accurately from a guard house than from one of the stations, and a man can go and change

* Paper read before the Manchester Association of Engineers.

† Gas engines compound of 1,000 i.h.p. can now be obtained to order.

the insulator at once, and remove anything that may have fallen against the main.

The receiving station will be on the north side of London, and will only contain the step-down transformers and a switchboard. One-third of these transformers will have open circuits, and will have their exciting currents supplied by the capacity of the lines, and the rest will be of the closed-circuit type, as before. They will transform down to 2,000 volts, and in some cases to 5,000 volts. Circuits will be led from this station to the premises of the various electrical supply companies of the metropolis. Those which employ 2,000-volt distribution will substitute a distributing switchboard for their central stations. In cases where the mains are in a net, the connection will be made direct to the mains.

Where separate circuits are preferred, one-to-one transformers will be used to secure insulation, and the ratio will be adjustable if desired. Small direct-current stations will be supplied with alternating currents, and will remove their plant and transform down to the pressure they require. If the engineers cling to direct currents, they can put alternating-current motors down to run their direct-current machines. Their engines, boilers, and batteries will, of course, be no longer necessary. Large direct-current stations that employ feeders can either use alternating currents on the same system, or can have a number of small sub-stations; or they can have feeder transformers manipulated from our station.

It will be best for the existing electrical supply companies to amalgamate with one another and with us, and, in fact, to cease to have any separate existence. The whole of the metropolis can then be worked direct with less expense. This would demand a large capital, though the supply companies will not need engines, boilers, batteries, or dynamos. These are only a small matter. Low-pressure mains demand a great deal of capital. Where mains already exist, new capital need be found only for increasing the electrical supply; and whether amalgamations could be brought about is a financial question only.

The cost of the plant for 10,000 h.p. comes out as follows:

Twenty gas generators	£8,000	
Steam generators	1,500	
Automatic fuel conveyors	1,000	
Electric way motor sidings	1,200	
Liquor tanks	6,200	
Two gasholders	16,800	
Two tanks	15,000	
Dust vessels	500	
Condensers and sulphate of ammonia plant	4,000	
		54,200
Thirty-seven gas engines	31,600	
Eighteen dynamo-electric machines	35,000	
Exciters and engines	2,000	
Transformers	12,000	
Switchboard and gear	3,000	
		83,000
Line, including poles and insulators		80,000
Receiving switchboard	3,000	
Receiving transformers	10,000	
Connecting mains in London	10,000	
		23,000
		£240,200

Besides the cost of the land, which will be a very nominal sum compared with the cost of land near populous centres, and the necessary buildings, there are various contingencies to be met, such as the possible necessity of underground mains across railways. The costs of way-leaves, and perhaps of parliamentary powers, must be faced, so it will be necessary to have a paid-up capital of some £400,000, and in order to make it worth while to carry out this scheme, there must be a prospect of a handsome profit on £400,000 with a maximum output of 10,000 h.p. at the generating station.

Taking the maximum output at 10,000 h.p., or 7,500,000 watts, the maximum power in London will be 5,400,000 watts.

On the assumption that our first power is used for lighting and almost no motors are used, enough lighting can be taken up to utilise 5,000,000 watts during a heavy fog. This corresponds with a low average load throughout the year, and it will probably be safe to assume an average consumption of 1,000,000 watts only.

The loss in the leads varies as the square of the current, so the effective current throughout the year must be taken. It will be necessary to generate about 1,060,000 watts at the station as an average throughout the year. Taking the cost of coal at 4s. 6d. per ton, after deducting the value resulting from the distillation and complete recovery of residuals, this will cost £1,100 per annum.

The cost of power per year may be taken thus:

Coal	£1,100
Oil and sundries	1,000
Labour	1,200
	£3,300

The cost of generating, exclusive of interest, depreciation, and standing charges, thus comes out at less than a tenth of a penny per kilowatt-hour. The selling price may be taken as follows:

Cost of generation	£3,300
Trade expenses	3,300
Depreciation on plant at 5 per cent.	12,500
Interest on capital, making 7½ per cent. dividends	30,000
	£49,100

This amounts to 1·34 penny per kilowatt-hour. It must be remembered that 5 per cent. is a high rate of depreciation in a case where an average of six-sevenths of the machinery is idle. 1·34 penny per kilowatt-hour is the selling price to the local supply companies. They have to add the depreciation on their transformers and distributing mains and motors, and the interest on the capital invested in them, and the cost of collecting small accounts. As the prices in London vary from 6d. to 8d. per kilowatt-hour, there is obviously an ample margin. We are not so much concerned with what the companies charge their customers as with what they will pay us. It costs them at present more than 1·34d. per kilowatt-hour for coal, oil, and labour, without taking depreciation, trade expenses, and profits into account. It would therefore pay them to take power at considerably over our price, say, 2½d.; and, rather than add more plant in the case of extensions, it would pay them to give even more.

In the above case the worst conditions, those of lighting a city subject to fogs, have been taken. Power taken constantly can be supplied at a much lower rate. Factory engines run about 54 hours a week, and the load factor of a large number of engines can thus be taken at about one-third. We can therefore supply power in large quantities at 0·65d. per horse-power hour, notwithstanding the power load overlapping the maximum lighting supply. Large steam engines can develop power at less than 0·65d. per horse-power hour; but it must be remembered that the power actually used is only a small fraction of the brake horse-power of an engine. In addition to this, an engine and boiler with a varying load works very inefficiently. An engine and boiler in a factory can therefore be replaced by electric motors of very much smaller nominal power, as the elaborate systems of countershafting and belts can be avoided. In addition to this, the efficiency of a motor is fairly high on light loads, and the motors need never run idle.

The Applied Uses of Electric Energy.

The area of application of electric energy is widening like the folds of an opening fan. To merely enumerate the distinctive applied uses would almost fill up the time at our disposal. We will, however, briefly indicate a few of the more salient examples in the arts of metallurgy:

The recovery of gold by electric amalgamation.
The production of aluminium.*
The cheapened production of phosphorus.
Extraction of metals.—Electroplating.
Electro-Fusion.—Welding and annealing of bars.†
Textiles and Dyeing.—Employment in sorting delicate colours, and for the tinctorial art by electrolytic decomposition.
Chemical.—The production of alkalies and chlorine by electrolysis, tanning, and laboratory use.
The Art of War.—Flash signalling, luminous projection, firing repeating guns, and explosive work.
The Safety of Ocean Transit.—Signalling, controlling machinery for propulsion and steering, and ventilation.
Domestic.—For lighting, cooking, boiling, and heating.
Ventilation, knife-cleaning, shoe-brushing, nursery use, sewing-machine driving, and for laundry work.
Agriculture.—Already described.
Engineering.—Partially described.
Commerce.—The transmission and repetition of thoughts and impulses enclosed in speech, by the telegraph, the telephone, and the phonograph.

N.B.—The author has received information from, and now thanks, the following firms and gentlemen and his friend, Mr. James Swinburne: M. Emil Huber, the Maschinen Fabrik Oerlikon, bei Zurich; Herr W. Lahmeyer, of W. Lahmeyer and Co., Frankfort; Mr. C. E. L. Brown, of Messrs. Brown, Boveri, and Co., Baden; The Deutsche Elektricitats Werke zu Sachen, Germany; Mr. Thomas Parker, The Electric Construction Company, Wolverhampton; The Crompton Electric Lighting Company, London; Mr. Chas. Brown, of Bâle; Mr. S. Russell, of Silvertown Cable Works, London; Mr. J. Bailey, The Metropolitan Electric Supply Company, London; and for certain of the lantern slides to Prof. Hele Shaw, Liverpool; Messrs. Ashmore, Benson, Pease, and Co., Limited, Stockton; Messrs. E. P. Allis and Co., Milwaukee, U.S.

From "Currants."—A story is told of a good lady of Slaithwaite who, on a visit to Huddersfield, asked the foreman of the electrical gang at work in the streets, the way the "leet" was made. The foreman replied that electricity was generated by currents. The woman, thinking that "currants" was the word used, straightway went and purchased two pounds of that toothsome commodity. When she found that the electric light could not be made out of the dried fruit she had purchased, she consoled her somewhat ruffled feelings by remarking that "If it ain't bahnd to mak' t' leet, it'll coom in for makkin' t' Kersmas puddin'."

* "Notes on Aluminium and its Production by Electrolysis and Electro-Fusion." By B. H. Thwaite. *Proceedings* Sheffield Metallurgical Society, 1891.

† Messrs. Clark, Chapman, and Co., of Gateshead, have had, in almost hourly use, for the last two years, a complete electric welding plant. They also use the electric energy for their heavy travelling crane.

LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. IX. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

ST. PANCRAS.

The St. Pancras authorities, and especially the energetic clerk, Mr. T. Eccleston Gibb, must be congratulated upon the interesting and comprehensive report issued upon the electric lighting scheme. For years municipalities have been waiting for definite and authoritative figures. Now we have them. It is true these figures are those of preliminary work, and of a first year's work, thus giving only a glimpse of what the true returns under normal full working conditions will be; still they are sufficiently clear to enable those who run to read. We have the cost to a London authority of an installation providing for a maximum of thirty thousand 16-c.p. lamps and ninety arc lamps. This amount is £92,246. 14s. 10d.; for the sake of round figures, let us say £95,000. If we may be permitted to say so, this is a very moderate cost. Ignoring the arc lamps, it would amount to about £3 per lamp, and as it is by various authorities estimated that the return per annum of each 16-c.p. lamp is £1, the interest on £3 at 3½ per cent. is something less than 2s. 1d. If the £3 is borrowed for thirty years, repayable in equal instalments, the repayment takes another 2s. These two items give, say, 4s., leaving 16s. to pay all other expenditure. Now we imagine that with a well-regulated central station the total expenditure under normal conditions should not be more than 60 per cent. of the receipts, or 12s.—bringing the grand total to 16s., leaving a balance of 4s. upon each 16-c.p. lamp in favour of revenue, and we trust ultimately in diminution of rates. We have always favoured municipal authorities taking the electric lighting in their own hands, maintaining that the work can be done far more economically and better by this than by any other means. When this is done, however, it is necessary to have a competent engineer—in fact, to have the best experience obtainable. It is a mistake to employ a man with less experience because his terms are ten pounds less. The diminution of one bill by ten pounds may mean the increase of another by a thousand pounds. In the figures we must direct attention to the enormous cost of "trenches" in the metropolitan district. From the accounts trenches cost £13,167, conductors £17,900, and engines and dynamos £18,100. However, all these figures speak for themselves, and we prefer to say a few words upon the future policy of St. Pancras. Advice freely tendered is seldom followed or appreciated. The estimated revenue is £13,000. To pay interest and instalments of borrowed money will take, say, from £6,000 to £6,500 a year. This leaves about 50 per cent for working expenses, which is hardly enough, but with great care the £13,000 income might be found enough for all purposes. It is evident, however, that extensions will rapidly bring into play the £20,000 or so of trench work and mains, expenditure now lying idle. If, as we surmise will be the case, then the returns will be largely increased in proportion to the expenditure, and there should be a good balance left after all expenses had been paid. Counting on this balance is to some people like counting chickens in the egg—

foolish; yet it will come, and for some time might well be used to pay for necessary extensions, instead of charging them to capital. We should like to see municipal bodies charge only the first installation—supposing it to be as large as this—to capital, and for extensions, out of revenue. Repay the capital as agreed upon, and when paid off, use the money thus freed for municipal improvements. The ratepayers, it can easily be shown, would reap benefits both directly and indirectly if this were done.

WOODHOUSE AND RAWSON.

It has been our painful duty in past years to comment on the balance-sheet of this company, but never has the duty been so irksome as now. Previous balance-sheets have shown a good thumping profit. We do not say that in our opinion the profits thus shown were authorised, but certainly the shareholders under the circumstances were not likely to look too closely into the accounts. This year we have an admitted large deficit. We have no sympathy with the shareholders at not getting a dividend. They knew the kind of business carried on, they acquiesced in that kind of business, and they must therefore take the rough with the smooth. As a rule, the shareholder does not care what is done provided you give him his dividend—the larger the better. Most shareholders are bulls or bears—the one set are on the look out for a rise, the other for a fall. The genuine investor is a very small quantity. In previous years we practically exhausted the vocabulary of animadversion upon this company's affairs, and, for once, prophetic utterances have been verified to the letter. If we had had the knowledge of to-day when writing in our issue of October 17, 1890, or November 20, 1891, not a single word of these articles need be altered. What now can be said in favour of the company is rather the question, than what can be said against it. There seems to be a certain *bonâ fide* trading business, though the exact value of the trading is a kind of unknown quantity. Assume, however, that such business results in a net profit of 10 per cent., and that it amounts to £120,000 a year. This would admit a 5 per cent. dividend upon £240,000. No amount of manipulation of the figures of the balance-sheet will, we imagine, show a better state of affairs than those assumed. Of course, the gross profits ought to be sufficiently large to leave this 10 per cent. after all expenses are paid. The capital of the company is close upon £622,000, against £382,000 of which, if a 5 per cent. dividend is to be earned, there is no trading business to earn it. We take it, then, that this amount—viz., £382,000—is the portion of the capital which has been created and is used for company promotion or for speculative purposes. It may be said, however, that a part has been used to commence branches and businesses that as yet have been carried on at a loss, and which may eventually realise a profit. A careful consideration of figures past and present lead us to the conclusion that £240,000 is an ample capital for the trading and manufacturing business concerned.

CORRESPONDENCE.

"One man's word is no man's word.
Justice needs that both be heard.

MULTIPHASE TRANSMISSION OF POWER.

SIR,—I have read with great interest the valuable paper presented by Mr. B. H. Thwaite to the Manchester Association of Engineers.

Although this communication is still "to be continued" in your esteemed journal, no mention has been made up to date of the fact that the Lauffen Frankfort power-transmission plant, as well as the more recent but commercial installation at Heilbronn using the multiphase or "Drehstrom" system, have been the joint production of the Allgemeine Elektricitäts Gesellschaft and the Oerlikon Works. I beg, herewith to call attention to this, to us important, fact that the great Berlin firm—the Allgemeine Elektricitäts Gesellschaft—which we represent in Great Britain—has very materially contributed scientifically and commercially to the development and success of the multiphase generation, transmission, and distribution of electrical energy.—Yours, etc.,

F. T. EGGERS, General Manager.

Electrical Company,
122 and 124, Charing Cross-road, W.C., Dec. 19, 1892.

CHELTENHAM.

[The following is Mr. Hall's report referred to in our last issue, and should be read in conjunction with that of Prof. Ayrton previously given.—ED. *E. E.*]

Mr. Hall's Report.—In accordance with your instructions of the 24th February, 1891, I beg to report on the best system to be adopted for introducing the electric light for the purposes of public and private lighting in Cheltenham; under the provisions of the Cheltenham Electric Lighting Order, 1892. Apart from the so-called systems of individuals or companies, electrical distribution may be divided into two great systems or divisions, which are usually known as alternating and continuous; both are regularly used in England and on the Continent, and each does good service under the conditions for which it is adopted—probably the best English examples of stations on the alternating system are Deptford with Ferranti machines, and the City of London with Mordey machines. It is now generally recognised that the field for low-tension continuous currents is confined to supplying within a very small radius from the works; and where, in such districts as St. James's and Pall Mall, the area is small and the demand large, there can be no question as to which is the right policy. Where the distances are very great and the amount to be supplied at any one point very small, the low tension must give way to high tension, and the simplicity of the alternating transformer, which will reduce the high tension in the mains to low pressure in the consumers' wires, renders the use of high-tension alternating currents most desirable. At the same time, it is right to say that an installation is being erected at Oxford, in which it is intended to use high-tension continuous currents and to transform down to low tension near the consumers, but this involves the use of moving machines, admirable in themselves, but having the weakness of all moving machinery unless attended to at all times, the cost of which practically prohibits it. Alternating currents have, no doubt, some disadvantages, the principal of which are that secondary batteries cannot be used either for receiving or discharging, and up to the present time small alternating motors have not been quite so successful as those constructed for continuous currents, but the demand in Cheltenham for small motors is not likely to be on a sufficient scale to warrant the setting aside of the more economical system to provide them, and the more, that there are several very promising machines now being offered, though not yet commercially obtainable. The extent of area of supply, within which mains must be laid within two years, consists of the following streets: High-street, Ambrose-street, Clarence street, Manchester-street, road to Great Western Railway Station, Colonnade, Promenade, Queen's-circus, road from Queen's-circus to Westal-green, Montpellier-walk, Pittville-street, Portland-street, Evesham-road, and Winchcomb-street to Pittville Gates, with extensions in such directions as may be demanded by householders upon their complying with sections 21 and 22 of the order. These extensions may and probably will be required along Lansdown-road to the park, up the Bath-road to the neighbourhood of the college, to Bays-hill and to Pittville; but it is impossible to say in advance in which direction the extensions will take place. The reasons for choice of a system therefore resolve themselves in (*a*) Which is the most economical in capital outlay? (*b*) Which lends itself most readily to extension without interference with the works first put down? (*c*) Which shows most economy of maintenance? and (*d*) Which gives the greatest convenience of distribution? On all points except economy of maintenance, high-tension alternating currents have the advantage, and in this matter it is most difficult to institute comparisons where probably the personal equation of management is frequently the largest

factor. The site selected is adjoining the destructor, the reasons for the choice being The site is in hand. The chimney stack is built. There is 60 h.p. to 70 h.p. available at all times. Its proximity to the Midland Railway will enable coal to be delivered to the boiler-house without the cost of carting and unloading. Reduction of standing charges, such as weigh-clerk, timekeeper, and superintendent, all of which would be shared with the existing works. Abundance of water, the avoidance of smoke and noise in the town. The current will be generated at the central station at a pressure of 2,000 volts, and conveyed along highly insulated concentric cables, each consisting of 19 No. 16 copper wires, which will transmit all the current for public lighting, and for about 5,400 16-c.p. and 8-c.p. lamps to St. George's square, along Ambrose street and Manchester street, to sub-station No. 1, from St. George's square to the sub-stations shown at the corner of the Colonnade, at Cambray, and near the new club, in highly insulated concentric cables proportionate to the energy to be transmitted, drawn into tubes formed of paper and treated with ozokerit, and embedded in the concrete walls of the conduit which carries the low pressure mains. A specimen of the paper tubes accompanies this report. At the sub-stations transformers will be placed, the number of which will be increased from time to time as further demands for light arise. They will be worked in the proportion of 20 to 1, thus reducing the pressure in the distributing mains to 100 volts. The low pressure system will commence at St. George's square, and in the first instance will be extended along High street to Bath road, and from High street along the Colonnade to Queen's circus, and from sub-station No. 1 along Clarence street to High street. It will consist of four bare copper strips each 1¼in. × ⅛in., and two each ⅝in. × ⅛in., carried upon porcelain insulators in a cement conduit 13½in. in width, and arranged upon the three-wire system. By increasing the number of transformers it will be possible to supply any quantity of current that may be required in the streets named. In the wall of the same conduit it is proposed to place paper tubes, into which will be drawn high pressure concentric cables, the lamps being arranged for lighting in series so as to reduce the cost of the mains, all the street lighting being controlled from the sub-station No. 3 at the junction of the Colonnade and High street. It will be necessary to exercise great care in arranging the height and distance apart of arc lamps in the Promenade, so as to obtain a brilliant effect with an equal illumination in all parts, and they should be suspended over the centre of the roadway, as it is only at that point that a sufficient height can be obtained without obstruction from the branches of the trees. In High street and similar places, where the shops and houses are built up to the line of the pavement, the lamps would be slung from chains, which may be stretched across the street from building to building, thus avoiding the obstruction caused by the ordinary lamp pillars, and placing the lamp in its best position. In each street the wires will be arranged in two circuits, one of which will supply about two-thirds of the whole number of lamps, and the other about one-third, the one-third circuit including the lamps at the intersection of cross streets, and any other which it may be necessary to keep alight all night, the two-thirds circuit supplying all those lamps which may be extinguished at, say, 11 or 11.15 o'clock p.m. The lamps in each circuit will be supplied from a separate transformer, which will be switched off and on with the light, thus obtaining the light in the most economical manner and with a smaller loss of energy than by any other system, the transformer, being designed to suit a known constant load, can be adapted to work with the maximum efficiency at all times. Should it be desired at any time to add incandescent lamps over the footways for special occasions, they can be supplied from the low pressure system in the same manner as the private houses are supplied along any part of the streets in which such low pressure system is provided. With respect to the means of supporting the lamps in the Promenade, the width to the centre of the roadway (25ft.) is much too great for any satisfactory form of cantilever to be used. The choice therefore will rest between centre pillars, a light girder or arch, and a chain. Of these, centre pillars, such as are used in Euston and Tottenham Court roads, would entirely destroy the character of the avenue, and be most undesirable; arches, if below the general line of the trees, would tend to be obtrusive, and would be somewhat suggestive of a large railway station; girders, if of open design, say single triangulation, and placed very high among the branches, might not be noticeable during the day; chains, from lofty iron posts, would be least objectionable during the daylight, and this system would readily lend itself to an alteration of the level of the lamps to suit the varying conditions of the surrounding foliage. Provision has been made for separate transformers for the assembly rooms and theatre, in case they decide to take current instead of running their own machinery. The installation at the central station will consist of two sets of engines and dynamos complete, each of which will give an output of 40,000 watts, and one set of engine and dynamo complete to give an output of 100,000 watts, a maximum of 180,000 watts, or 48,000 candles; the buildings are designed for continuous extension, and it is proposed to adopt the 100,000 watts set as the unit, adding engines and dynamos of this size as the demand increases. As soon as the portion already described is in working order it is intended to proceed with the extensions along the streets named, being the second part of Schedule A of the order, providing with these extensions another unit at the central station. The boilers are proposed to be: One existing tubular boiler in the destructor, 12ft. by 7ft. 6in.; one additional tubular boiler 20ft. by 7ft. 6in., to be worked at a pressure of 80lb. per square inch, and heated by the destructor fires. In the boiler house after the commencement two *Lancashire* boilers each 20ft. by 6ft. 6in. diameter with Galloway tubes, to be worked at 120lb. per square inch, and additional boilers of the same [illegible] to be added as the demand for light arises. The cost of the [illegible] stations, sub-stations, and high and low tension mains, and [illegible] lamps in the High street from Tewkesbury road Bridge [illegible] Bath road, Ambrose street, Manchester street, [illegible] Colonnade, Promenade, Queen's circus, and Montpellier [illegible] the Gordon lamp, and Winchcomb street will be about [illegible]. The extension of the high tension and the low tension [illegible] the streets, detailed in Schedule A of the order with one [illegible] unit complete at the central station, but exclusive of lamp [illegible] and lamps for street lighting, will be about £6,400 ext[illegible] the machinery will have a maximum output of 280,000 [illegible] which is equal to 9,000 8-c.p. lamps or, exclusive of street [illegible] ing, of 7,100 8-c.p. power lamps available for sale. [illegible] demand reaches 180,000 watts an additional unit should be [illegible] together with an additional boiler, and in like proportion [illegible] output of 600,000 watts is reached, so as at all times [illegible] reserve of at least one complete unit and one boiler; after [illegible] have been reached, the reserve should be two complete units. The conduits are all designed so as to be of sufficient size for [illegible] and the estimates are based upon the use of the highest [illegible] of material so as to avoid as far as possible recurring [illegible] repairs and the subsequent interruption of traffic. The [illegible] distributing mains, and transformers are sufficient to [illegible] 1,200 lamps each of 16-c.p. between New street and the [illegible] nade, 4,500 lamps between the Colonnade and Cambray [illegible] lamps between Cambray and the Bath road, 3,800 in the [illegible] menade to the New Club, and 1,500 between the New Club [illegible] the Queen's Hotel, together with all that can be [illegible] Clarence street, in addition to the theatre and assembl[illegible] The advantages of dealing with the question in the [illegible] described are that The capital involved is limited, [illegible] soon whether there is a sufficient demand for the elec[illegible] The necessary extensions can be made as the demand [illegible] arises. No plant is purchased until there is a reasona[illegible] bability that it can be immediately set to work to [illegible] thus reducing the possibility of loss to a minimum. [illegible] variety of work to be done, it will be desirable to div[illegible] number of sections, some of which can be best carried [illegible] tract, and others by purchasing the materials and plac[illegible] position by the Corporation workmen. Probably the [illegible] factory divisions will be: Central station buildings, [illegible] engines, dynamos, transformers and switchboards, [illegible] boilers, purchase from a maker of repute; conduit and [illegible] Corporation workmen; high tension mains laid complete [illegible] copper strip, contract; copper strip, fixing, Corporat[illegible] lamp pillars, contract; lamp pillars, wiring and fixing, Corporation workmen; lamps, purchase from makers.

Cost of Running (Preliminary, say, First Year.)

Fuel, 575 tons at 7s. 6d.	£215 0 0	Arcs, 38 at £15	£[illegible]
Oil and waste	65 0 0	66,720 Board of Trade units at 6d.	1,6[illegible]
Carbons for 38 lamps at £3	114 0 0	Balance (adverse)	[illegible]
Labour and supervision	1,018 0 0		
Depreciation, repairs, and interest	1,174 16 6		
	£2,586 16 6		£2,5[illegible]

Cost of Running (after Extensions, say, Second Year.)

Fuel	£350	Arcs, 38 at £15	£5[illegible]
Oil and waste	80	174,000 Board of Trade units at 6d.	[illegible]
Carbons for 38 lamps, at £3	114		
Labour and supervision	1,452		
Depreciation, repairs, and interest	1,790		
Balance (profit)	1,144		
	£4,920		£4,9[illegible]

The street lamps are assumed to be, 22 in the Promenade, [illegible] the High street between St. George's square and the [illegible] one in Clarence street, and one in the triangle at St. [illegible] square; and the cost will be practically the same as gas [illegible] large lamps now used in High street and Promenade. [illegible] balance sheets it is evident that the preliminary [illegible] alone will result in a deficiency of £318 1s. 6d. per [illegible] that as soon as a second unit is added, the earning [illegible] sufficient to cover not only the extra cost of running, but [illegible] interest on the extensions, and leave a profit equal to [illegible] 5 per cent. on the capital, or you will be able to reduce [illegible] to 5d. per Board of Trade unit, which will be equal to [illegible] about 3s. 4d. per 1,000ft., and any further extensions [illegible] central station plant will enable you to still further reduce the [illegible]

COMPANIES' MEETINGS.

WOODHOUSE AND RAWSON UNITED, LIMITED

Under the presidency of Sir Rawson Rawson the third [illegible] general meeting of the above Company was held yesterday at [illegible]

Cannon-street Hotel, in the presence of a large number of shareholders. After the Secretary had read the notice calling for the meeting,

The **Chairman**, in moving the adoption of the report (which we give in another column), said that the occasion of his addressing them that day was important to the future of the Company. Following the precedent of Lord Aberdare, he had committed to paper what he had to say. He remarked that he would have to deal in detail with some matters. It was his wish and that of his colleagues to give the shareholders the fullest information on all matters concerning the Company, and to place them in a position to correctly estimate their position and prospects, and form a judgment as to the wisest course now to be followed. He commenced by analysing the losses during the past year, in order to show them the causes from which they had arisen, and to satisfy them, as he hoped to do, that those causes were exceptional and would not recur. The first of those, as shown in the profit and loss account, was that relating to the lamp settlement action amounting to £14,472. They were aware that this Company was prevented by the resolution of the action of the Edison and Swan Company from manufacturing and selling incandescent lamps in the United Kingdom. As a result, they were prevented from utilising their valuable lamp patents, which had made the reputation of the Woodhouse and Rawson lamp. Subsequent to that action, the Company entered into arrangements with the British Electric Light Company to work under the license obtained from the Edison and Swan Company. Owing, however, to a technical and legal point, they found themselves in a position in which there was no alternative but to give up the manufacture of lamps, or run the risk of heavy damages at the suit of the Edison and Swan Company. By those means they were deprived of one of the sources of profit from the beginning. In order to settle the action of the Edison and Swan Company, they had to incur a heavy loss, the major portion of which was due to writing down the stock and plant in the department. Next November, however, when the lamp patents expired, they expected to resume the manufacture with the advantage of the reputation which they had already established. In the meantime they hoped to dispose of a considerable portion of their stock at a rate above even that at which it was stated in their stock-sheet. The next item was that at Kidsgrove, amounting to £17,000 odd, they had lost on contracts taken over from the vendors, and works taken by them whilst in the service of the Company; also the debts incurred by the failure of the vendors' firm. In the matter of the Kidsgrove purchase the Directors considered themselves justified in relying upon the judgment of their then manager. The reports which he had made to the Board spoke in unqualified terms of the advantageous character of the purchase, of the excellent business being done, and of the opportunities which the acquisition of the works would confer for developing the other business of the Company. At that time it was absolutely necessary that they should manufacture certain classes of electrical apparatus and machinery which they had not hitherto undertaken. They had lost customers through not being makers of some kinds of apparatus. Under the present management the contracts undertaken, with very few exceptions, had been profitable, a large amount of business had been taken up and had been carried out successfully. As their manager informed them, orders to the extent of nearly £50,000 had been offered to them, and which they could have undertaken if they had had the necessary capital. The work done had added to the reputation of the Company for good work. The third item was the loss on the trading and depreciation, amounting to £37,000. As far as they could make out, nearly £30,000 of that might be said to be depreciation, and not actual trading loss. A portion of the loss was due partly to agencies which had since been closed as unprofitable, and the initial expenses in forming new branches, several of which had only been in operation for four or five months, and they were now beginning to pay their way. The most prominent was at Johannesburg, where most lucrative prices were being obtained. A great deal of the loss on trading was due to their Cadby Hall factory, which they proposed to close after Christmas for a time, and the expenses there would be reduced to a very small item. Standing charges which had amounted to £6,000 a year, would then be converted into a profit of about £600 per annum. The sum of £5,650, which was the next item, for depreciation of patents, was the proportion which they had decided to write off each year. They had acquired over 20 patents last year, of more or less value, and at a mere nominal sum, or on the terms of sharing a small portion of the profit with the inventors. That was the method generally adopted. With regard to the Epstein patents, it had been shown to their experts that the accumulator made under them was destined to prove one of the most valuable inventions of the day. He emphasised this by referring to the use of the batteries at Birmingham, and by the fact that one of the largest firms had undertaken to supply motors, etc., and the Epstein Company the accumulators, and there was little question that a majority of the tramway companies would adopt the Epstein system. The reason why the Company did not work all its patents itself was because a large amount of capital was required, and the only way of realising a profit on a very valuable invention, worth £100,000 to £200,000, was by selling it to a company. With reference to the depreciation of securities, what was only worth £1 to-day might next year be valued at £2, £3, or £4, everything depending upon the market value. Their securities had not been bought, but were held in companies brought out by their assistance. The Chairman then considered the special report of the auditors, and which was mentioned in the report on the balance-sheet. Several questions raised by the auditors at the date of their signature on December 12 had since been cleared up to their satisfaction. That special report explained that the reason for the books not having been balanced was because the Directors had not employed a sufficiently competent bookkeeper, but at present they were in charge of an experienced man. Regarding the vouchers which still remained to be produced, the Chairman said that the Board expected them to be shortly forthcoming, and that the amount would not be inconsiderable. As far as the repayment of the guarantee, and which had the sanction of a special meeting, he read a paragraph about it from the original prospectus. It had been stated in last year's report that the prospects of the Company were extremely promising. Well, they had then secured the contract for the electric lighting of the Champs Elysées in Paris. Half the capital had been subscribed there, and if it had not been for the great depression, the other half would have been raised here. As a result, the opportunity of making a profit over that concession had been lost. Other matters were the Oncken Company and the Epstein patents. In the former, owing to the small amount of capital subscribed, they had to take their profit in shares instead of in cash, whilst in the case of the latter they had considered it prudent to postpone bringing it out. The Directors had viewed with considerable anxiety the probability of finding £75,000 in cash to repay the vendor company on the 1st of July last. They succeeded in compromising the scheme by paying £12,000 in cash and £51,000 in debenture stock, instead of £75,000. The Company had considerably reduced its expenses, and by the end of the year all the sources of loss would be eliminated. He hoped during the coming year to obtain a fair profit, but for that purpose it was necessary to pay off credits and have a balance for working capital. The sum required, though not immediately, was £60,000, and they proposed to raise that by mortgaging their free investments, amounting to £70,000, and the stock-in-trade and merchandise, which amounted at the date of the balance-sheet to £10,000. The rate of interest to be paid was high—namely, 10 per cent.—but it was only a temporary loan for 12 months, and would be issued *pro râta* to the shareholders and debenture holders. The balance would enable them to undertake profitable contracts, which were offered to them to the extent of from £30,000 to £40,000 as soon as they had the necessary capital. If it should fall below £60,000, the loan would be immediately repelled. Counsel had informed them that they had the power of creating a specific charge upon the Company's assets, with the exception of the freehold and leasehold premises, which were already mortgaged. The Directors invited the shareholders to support them in that direction, and they thought they were justified in so doing, seeing that the branches and central control were in thoroughly competent hands. He then moved the adoption of the report and accounts.

Sir John Stokes seconded the motion.

Dr. W. Squire did not think it was likely that they could raise additional capital until something more was known about the actual business of the Company, and in order to raise the question he proposed, in no hostile disposition, to move that the report be not adopted, and that a committee of investigation of the shareholders should be formed and report upon the affairs of the Company. He disclaimed any imputations or suggestions in making these remarks. Since the first two years of the Company's existence, its condition had changed. Formerly they received dividends; now they came to a loss of £120,000, and it was difficult to offer any explanation for the difference. He noticed that industrial undertakings had the knack of being exceedingly prosperous at the beginning and then they collapsed, and that was always the case when the whole of the shares at the commencement had not been taken up by the public. They could make their profit for a year or two as much as they liked; put down the stock, goodwill, patents, and generally unsaleable securities for any amount desired. The accountant was unable to check the figures, he having to take them as stated to him, and the result was a magnificent balance-sheet certified by well-known accountants. The accountant could, however, do one thing—he could insist that the stock from one year should be debited to the second year. The ultimate result was a heavy loss.

A long and exciting discussion then followed, and among those participating were **Mr. Battye, Messrs. Bacon, Lockwood, Griffith,** and others.

Mr. F. L. Rawson also addressed the meeting, as did also **Mr. Pope** and **Mr. Statchbury** (manager of the Company).

Ultimately **Sir Rawson Rawson** read the following amendment, proposed by **Dr. W. Squire**, and seconded by **Mr. Bacon**: "That a committee of consultation, consisting of five of the principal shareholders, with power to add to their number, be appointed to confer with the Directors as to the present position and future prospects of the Company, and report to the shareholders at the earliest possible date, and also that the balance-sheet and statement of affairs from August 1 to December 31, and submitted to the special meeting to be held as early as possible; further, that the consideration and the adoption of the report be deferred until the report of the committee be 1892, be prepared under the supervision of the committee received."

This was put to the meeting and carried unanimously. The committee formed comprised Messrs. Pilling, Whateley, Griffith, and Bacon, Dr. Squire, and General Fyfe.

Sir Rawson Rawson moved that the Directors be authorised to raise a sum not exceeding £20,000 on the security of the floating assets of the Company, and that for this purpose the borrowing

powers of the Directors, according to the articles of association, be increased from £250,000 to £265,000.

This was seconded by **Sir John Stokes**, and was adopted.

The existing Directors and auditors were then re-elected, and the meeting adjourned as set forth in the amendment.

THE ELECTRIC CONSTRUCTION CORPORATION, LIMITED.

Under the presidency of Sir Daniel Cooper, Bart., chairman of the Company, the fourth ordinary general meeting of the Electric Construction Corporation, Limited, was held on the 16th inst. at the Cannon-street Hotel, in the presence of a large number of shareholders. After the secretary (Mr. W. Samson) had read the notice convening the meeting (the proceedings of which throughout were of an animated nature),

Mr. Dunnill rose and complained of his solicitor, Mr. Wainwright, having been excluded from the gathering, and he wished to put it to the shareholders whether he should not be permitted to be present.

Sir Daniel Cooper said that it was a very unusual thing for a person who was not a shareholder to come in and interfere with the proceedings. The Board would, however, allow Mr. Wainwright to be present.

The **Chairman** then remarked that he was glad to see them all there that day, and he hoped that many of them, after what they heard, would be much better satisfied when they went away than they were when they entered the room. In order that he might not under any impulse say what might be considered a little strong, he had written down what he had to say so that it could be produced against him, and in that way he was sure to be able to answer for what he had said. Three months ago he very reluctantly and at the entreaty of his colleagues undertook the chairmanship of the Corporation, and from that day until then his best endeavours had been directed towards the re-establishing of the credit of the Corporation. He and his colleagues had stuck manfully to the ship, and had obtained for it within a few weeks a position it had never held since the day it commenced work. Since his election as chairman, the time of the Corporation had been a critical one, and the Directors, individually, and collectively, had found money and credit so as to enable them to meet all demands, and to do that they had had to incur responsibilities which he did not think any other board of directors would have done. But they had faith in the soundness of the Corporation, and they thought that the shareholders would appreciate their efforts. The Corporation, when it started, had to make its name like all new companies, and had to obtain work at times under onerous conditions. The profits earned, therefore, should not be gauged from an old-established Company. He instanced the work at Manchester-square station, and near Rathbone-place, the overhead railway at Liverpool, the works at Oxford, and the South Staffordshire tramways. Those important orders, to some extent, gave the Corporation a footing and a name in the trade, and were a guarantee for future orders, of which they had £60,000 to £70,000 in view. When the name of the Corporation was established it would enable it to obtain contracts on more favourable terms. The experience gained during the past three years would enable the Board to guide and manage the business more firmly and economically. As a body the shareholders had not supported the Corporation as they ought to have done in the issue of the preference capital, and the Directors had had to find the means to carry on the Company. Therefore from their practical knowledge, it would be a folly to declare a dividend. They now asked the shareholders to contribute towards the £100,000 second mortgage debentures, and help the Corporation. Mr. Duncan had issued a circular from a sick bed, and he thought that his notions were none of the brightest. He might instance his (Mr. Duncan's) remarks about the Electrical Power Storage, which was taken by the Electric Construction Corporation at a large price. From that day until it was leased to the present company the turnover gradually dwindled, and if it had been continued by the Electric Construction Corporation it would have vanished by this time. On the other hand, managed separately, it had regained its old output in 12 months, and this was increasing—the Corporation was receiving £9,000 a year as a minimum, and as it held the bulk of the shares in the undertaking it practically received all that was made by the Electric Power Storage Company. Sometimes they could not marry two companies. What they wanted was to get electricity in the accumulators and the other in a direct manner, and each business should be kept distinct, so that those who required secondary batteries would go to the Electrical Power Storage Company, and for the other system they could come to them. Mr. Dunnill, the holder of a few shares, had also issued a circular, which he (the chairman) trusted the shareholders would treat respectfully; but he hoped they would not be led away in a scare and destroy their property by statements that could easily be answered. As he had already mentioned, the present Directors had done a great deal in a short time to put the Company on a firm footing; they hoped with new blood to do much more during the year to concentrate the resources of the Company, and to confine the business to its legitimate work; but whilst they were doing that, they must not be harrassed by a committee of investigation, which would only have a disastrous effect upon the business of the Corporation, already seriously injured by the attacks of hostile shareholders. The Directors did, however, not wish to withhold any information from the shareholders who appointed the auditors, Messrs. Brodie, Paterson, and Co., who were most able and painstaking, and who would not pass any transaction which was not strictly correct. He was informed by their legal adviser that Mr. Dunnill's motion was out of order, but, nevertheless, it might not be out of place to state the conclusion which the Directors had arrived at. In the first place, he himself held as large an interest in the Corporation as the whole of the shareholders whose proxies Mr. Dunnill had obtained. He merely mentioned that to show that the Board had a very substantial interest in the property of the Corporation. The Directors had carefully considered the proposal for the appointment of a committee in the resolution embodied in Mr. Dunnill's circular, and they had come to the conclusion that there were very grave objections to a committee. The Directors of the Board, as now constituted, had nothing whatever to conceal, and if they considered their own feelings, they would welcome the appointment of a committee, but they were perfectly satisfied that it would be detrimental to the interests of the Corporation. As an example of this, he mentioned that a foreign contract, which they had had good hopes of securing, had gone beyond the Corporation on a statement made by the gentleman who had its disposal, that the rumours existing concerning the Corporation, and [illegible] as to its inability to carry out the work, had prevented [illegible] offering them the contract. The final settlement of [illegible] which they hoped they had secured was being suspended [illegible] the result of that meeting, possibly waiting to see whether the Corporation was in a position to carry out the contract, the [illegible] of which was about £50,000. But altogether apart from these considerations the Directors could not see that the appointment of a committee, or its report, could carry the weight with the shareholders which would the examination into the affairs of the Corporation which had just been made by the Electric and General Investment Company, and which had no interest in the Corporation. When a loan to the Corporation was required, that company caused an examination to be made of the books and accounts, and an expert reported upon the works. The result was that the Electric and General Investment Company agreed to [illegible] £50,000, which, he might tell them, was absolutely necessary to carry on the business of the Corporation. Surely that fact ought to carry more weight with the shareholders than the report of ten committees. For those reasons the Directors had come to the conclusion that they must resist as most prejudicial the carrying of any such resolution as indicated in Mr. Dunnill's circular. At the same time they would regard the passing of such a resolution as a vote of lack of confidence in themselves. He hoped that he had sufficiently impressed them with the gravity of the issue as affecting the future of the Corporation. As he was suffering from a severe cold, the Vice-Chairman would explain the figures in the balance-sheet. He thought that he was better able to do that than himself. They had had no managing director for some time, and in a large corporation like that it was very difficult to manage unless they had somebody who gave constant attention to the business. Mr. Courtenay, the vice-chairman, had been doing that without any pay, and in that way he had the details more at his fingers' ends than he had, because he (Sir D. Cooper) could not give the time or come to the City as he did. He then moved that the report of the Directors, and the accounts annexed thereto, be received and adopted.

Mr. J. Irving Courtenay (vice-chairman) responded with pleasure to the call of the chairman, who had so gallantly come to the assistance of the Corporation under the trying circumstances with which they were all more or less acquainted. He [illegible] the Corporation owed a deep debt of gratitude for the [illegible] financial support given it in the time of need by Sir Daniel Cooper, who has been loyally aided by the present Directors. He proposed to go through the profit and loss account and balance-sheet, and offer such explanations as might seem necessary. Taking the profit and loss account first, the head office expenses, [illegible] £7,870. 3s. 1d., were less than they were last year by [illegible], which he thought they would agree was a substantial reduction, and the Directors intended to still further reduce those items. The amounts under the head of "special expenses" were very large, but the bulk of them might be deemed to be exceptional, and not likely to occur again. For instance, the chief amount [illegible] allowances on contracts arose in the final settlement of accounts in regard to one important account, namely, that with the Metropolitan Electric Supply Company, Limited. There were questions of vibration and other legal questions [illegible] in the opinion of those who knew the [illegible] the arrangement come to between both companies was a [illegible] one. They were indebted for that friendly arrangement to the kind offices of Sir Henry Mance and Sir [illegible]. Another amount was for [illegible] to the [illegible] Chemical Agency, one of the subsidiary companies, in [illegible] tion of a licence for some of their patents which were [illegible] the proper working of patents which were sold by the [illegible] to the [illegible] Company, Limited. [illegible] Corporation had a very considerable interest in the [illegible] Chemical Agency. The last item of the [illegible] for [illegible] in connection with the [illegible] Corporation was bound to make a good [illegible] tions but following years benefited by [illegible] for new business. The [illegible] patents had been [illegible] account in the past year owing to [illegible] portant case known as the "Lane Fox [illegible]" which, he was glad to say, resulted in [illegible] Lane Fox. This, again, was an [illegible] would be felt in future years. [illegible] items under the head of special expenses might [illegible] chargeable to capital; at any rate, [illegible] revenue of one year [illegible] the Board's action in writing off all these charges [illegible] had the effect of very greatly strengthening the balance-sheet.

Turning now to the balance sheet, they would observe an item of £8,470 for difference between par value of shares sold and amount realised, which they had deducted from the reserve account set apart for that purpose; and that was a convenient opportunity for him to call their attention to the principle the Board had adopted, with the approval of the auditors. That was, not to value the shares they held in subsidiary companies at any other figure than their par value, but to create a large reserve fund as against them, so that when the shares were realised, should there be any deficiency, there would be an ample reserve to meet it. This special reserve was independent of the £18,000 reserve for general purposes, and a further reserve of £10,000 for bad and doubtful debts. The amount of shares held by the Corporation had been the subject of comment, but he asked them to remember that a large proportion of these shares were acquired in payment for various patents sold or licensed by the Corporation. They should, of course, preferred to have got cash, but that was not possible. It became necessary to develop and work the numerous patents owned by the Corporation in some way or other, and on the best terms they could get, and this remark applied also to the provisional orders. For legal and other reasons separate companies had to be formed. They invited people to assist them in forming them, and they hoped that in future these subsidiary companies would be a source of considerable income, the Corporation keeping itself to pushing and developing its manufacturing and contracting business, so far as practicable, upon cash terms only. They would have noted that there was a sum in cash—£3,115. 15s. 9d.—at the London and General Bank, Limited, which was in liquidation, of which £2,000 was on a joint deposit account on behalf of one of the subsidiary companies, as a guarantee fund in connection with patents sold to them. No official statement of the prospects of this liquidation had yet been made, but they were assured that no loss would accrue so far as this deposit was concerned. As stated in the report, the Directors did not propose that any dividend should be paid on the ordinary shares for the past year, but recommended that the dividend, at the rate of 7 per cent. per annum, be paid on the preference shares to the 30th September last, that £30,000 be placed to a suspense account, and that the balance of £26,862. 1s. 5d. be carried forward. The Directors believed that to be the sound course for men of business to take under the existing circumstances, and that the shareholders would approve that policy. The Directors would make every effort to realise some of the shares, and to make the balance of profit and loss account available for dividend purposes as soon as possible; and though the fixed charges were somewhat heavy, he saw no reason, with strict economy, both at Bushbury and at the head office, why a satisfactory dividend should not be regularly earned in the future. Coming to consider the work done at the Bushbury works, he mentioned that the past year had been a very heavy one there. They had turned out an increase in the amount of work in their ordinary business, and had also put down a system of continuous-current high-pressure distribution of electricity for Oxford, and during the exhibition at the Crystal Palace they delivered by the same system about 500 h.p. over a mile into the Crystal Palace from the central station. The Oxford installation, they were informed by Mr. Parker, had proved to be thoroughly efficient and reliable, and it would stand among the first of the installations in this country in the future as a means of supplying energy for lighting and power. They had also carried out the contract for the Liverpool Overhead Railway Company, a new departure in this country, or nearly so, putting down the whole of their power in the electrical portion of the engineering, carriages, and all necessaries for running the line. This line was expected to be in running order about the end of the year. They had manufactured and installed 7½ miles of an overhead system of tramways for the South Staffordshire Tramways Company, Limited, which was shortly to be opened for traffic. This work, he was informed, had been highly praised by the Board of Trade inspector. They would readily understand and appreciate that those contracts had many novel features, and being the first of their kind did not admit of the profit that was to be made when regular business was established, but they might look forward to these being the pioneer enterprises of future great business in that class of work. The works at Bushbury were now thoroughly equipped, and their capacity could be largely extended with great advantage to the Corporation, as the additional charges upon additional business would be very much less in proportion. Mr. Parker told them that he knew of a substantial amount of work in different directions, which he expected would be entrusted to this Corporation to execute. The value of these contracts must not be gauged by the precise cash returns, but must be regarded rather as contained in the valuable advertisement from such important works as the Liverpool Overhead Railroad and the South Staffordshire Tramways. Other important matters worked out by Mr. Parker and his staff were several inventions for the more economical production of zinc, chlorine, and alkalies, and to carry some of these into practical effect the Directors had founded the Electro-Alkali Company. These inventions promised success in their laboratories, and he hoped that Mr. Parker might in a short time be able to report that their commercial application was equally successful. The history of the transaction was this: The alkali patents were in the first instance transferred with other patents to the Electro-Chemical Agency, but when as the result of full experiments Mr. Parker arrived at the opinion that the alkali patents promised to be of great value, it was considered best to put them into a separate company, and they were bought back for preferred shares in the Alkali Company from the Chemical Agency, and they were now the property of the Alkali Company, in which the Electric Construction Corporation had a very large interest. The Chairman had already dealt with the remarks of Mr. W. W. Duncan about the Electrical Power Storage Company, which were, in some important particulars, incorrect. Mr. Duncan was unfortunately not present. The net profit when the Electrical Power Storage business was worked by the Electric Construction Corporation was never what Mr. Duncan stated it was, nor were the annual costs of administration what he stated; they were really about half the amount, because a portion of the account was for 17 months' working, and a large sum was included for carriage etc., which did not belong to administration account. He had explained the figures to Mr. Duncan last autumn, when he remarked that his explanation had knocked the bottom out of his criticisms. He had thought fit to repeat them in the public prints, but the reasons for his whole attack were obvious. Experience had shown that it was practically impossible to run successfully two businesses together which differ so much as do the storage battery and dynamo manufacturing business. The result was, that whereas the business had so seriously fallen off when it was worked by the Electric Construction Corporation, that it had nearly reached the point where no profit could be earned at all, they had, since it has been worked separately, nearly doubled the output and were still increasing it. He thought the shareholders would wish to hear further details from Mr. Parker of the important works he had alluded to, and later on he would ask him to address them. Coming to the important paragraph in the report dealing with the general financial position of the Corporation, he stated at the outset that the problem of how additional capital could be raised on terms which would be satisfactory to the shareholders presented some difficulties on account of the many interests which had to be protected. There was the first mortgage debenture issue at present of £150,000, then there were some preference shares, then came the ordinary shares, and finally there were the founders', whose rights had had to be safeguarded. He was glad, however, to be able to assure them that the scheme which the Electric and General Investment Company, Limited, after a very close study of the whole of the question (with the assistance of the most competent legal advice), had devised for them, was one which protected and preserved the rights of all existing interests, and in this connection it was right perhaps to tell them that they had had an advantage in dealing with the Electric and General Investment Company, Limited, which they should probably not have had if the arrangements had been made with others, by reason of the fact that the Electric and General Investment Company had a special knowledge of this class of industrial undertakings, and they had therefore been better able to appreciate the great potentiality for future work which this Corporation possessed. The problem was as to how £100,000 additional capital could be raised on terms which, while they were sufficiently attractive, were not unduly onerous to the Corporation, and the result was, he felt bound to say, to the satisfaction of the Board. They were raising £100,000 of new capital at a rate of interest at 6 per cent. per annum, which was no higher than the rate of interest paid upon their first mortgage debentures, and the scheme provided for this money to be repaid within a comparatively short period. Of course, it would be obvious that the money could not be raised on such exceedingly favourable terms without offering a bonus, and the form in which this was done was satisfactory both from the point of view of the future of the Corporation and also from that of the shareholders, who had the first right to subscribe the money. The bonus was given in the form of an income bond which was attached to each debenture, and was of a corresponding amount—i.e., the subscriber of every £10 second mortgage debenture received a bonus bond of £10 free of all liability, and this income bond would commence to carry interest from the date on which the debenture was drawn and paid off at par. The rate of interest would be determined for each year by the dividend paid on the ordinary shares of the Corporation for each preceding year. It was, perhaps, desirable that he should explain the procedure a little more fully by giving an example: Assuming that at the end of next year debentures to the amount of, say, £4,000 were paid off; then the income bonds to the amount of £4,000, corresponding to the debentures which had been drawn would commence to carry interest, and they would receive interest for the year 1894 at the same rate as the dividend that might be paid upon the ordinary shares for the year 1893. He had no hesitation in saying that, in his opinion, these debentures with income bonds constituted an exceedingly profitable investment; but he hoped to convince them that the terms were not unduly onerous to the Corporation, because the Board felt that the new capital of £100,000 would of itself produce the amount which was required to pay the interest thereon and to redeem the debentures, and if this expectation was realised it would be seen that the Corporation would obtain the benefit of this increased earning power at the cost of merely the interest paid upon the income bonds. On the other hand, the shareholders who subscribed for those debentures would make an exceedingly good thing, especially those whose bonds were drawn at an early date, because they would receive their principal back with 6 per cent. interest, and would at once rank with the ordinary shareholders for dividend without cost to themselves. This explanation of the scheme would, he thought, make it clear to every shareholder that if he wanted to secure the full benefit of the arrangement for himself, he could do so by taking up his proportionate allotment. In conclusion, it was a great satisfaction to the Directors that the Board had been strengthened by the addition of the Right Hon. David Plunket and Mr. James W. Barclay, both of whom occupied a leading position in the City, and with whose assistance the economies that must be effected in various directions would be judiciously and effectively carried out, and they felt con-

fident that with the support of the shareholders the Corporation could be made to take the first rank among the electrical properties of this country. He then seconded the motion.

Mr Parker, at the request of the Chairman, addressed the meeting. He said that the Vice-Chairman had referred to the work done at Wolverhampton, but he did not propose to criticise his remarks. In that town they had accomplished a very heavy year's work, and as the electrical business was not one which had arrived at a definite stage, the contracts of the year had contained a great deal of novelty. That novelty was necessary to the progress of the business and its prospects in the future, but it had fallen very heavily upon the staff and the factory. They had successfully put down and inaugurated a system of lighting at Oxford by high pressure continuous currents, which was successful and would no doubt be the forerunner of a great deal of business in the future, and they had secured valuable patents upon that system. The Liverpool Overhead Railway was practically completed, being the largest scheme of electrical traction engineering that had yet been attempted. It had called for much experimenting and invention to secure its success, which had been demonstrated. The South Staffordshire tramways contract was also the first of its kind that had been carried out. It was now completed. All those contracts had run through in this year. It would seem in taking the figures of the turnover that the profits had been small upon manufactures turned out at Wolverhampton, but by deducting the goods bought—such as engines, boilers, cables, etc., upon which the profits were small—it would be seen that the profits upon the actual manufactures at Wolverhampton had been good. The ordinary business of the firm had been fairly good throughout the year, and they had in hand at the present one third of last year's manufactures, and also machinery for the central stations at Manchester, Leeds, Coatbridge, and Burnley. They could not say that about Wolverhampton, although the committee had passed the matter. They had also had worked out in the laboratory some features which promised successful application, and upon some of these patents the Directors have decided to institute the Electro-Alkali Company, Limited.

Mr. Dunnill then asked whether the Chairman would allow his resolution to be put to the meeting, but was informed that it was out of order. He then asked why that was the case?

Sir Daniel Cooper said that the notice had been received too late by 24 hours.

Being ruled out of order, **Mr. Dunnill** stated that he would move as an amendment: "That the accounts be not adopted or passed; that the Directors be requested to amend the same by giving particulars of all the shares in subsidiary companies, licenses granted, and patents sold, and the amounts receivable in each case, and from whom; that this meeting be adjourned to enable this to be done, and that fresh accounts be delivered to every shareholder seven days before the adjourned meeting." Mr. Dunnill mentioned that more than a quarter of a million of their capital had been expended, not in manufacturing, but in exploiting companies and dealing in shares. What they wanted to know was what had become of the £250,000 which was represented by shares received or to be received. The Chairman had said that his holding in the Company was equally as large as the total number of proxies which he (the speaker) had obtained. The proxies sent to him, remarked Mr. Dunnill, were 5,389, and he did not know what amount there was at the meeting. Did the Chairman imply that he held more than 5,000 shares in the Corporation? He was of opinion that the shareholders should have an investigation made by gentlemen totally independent of the directorate.

Mr. W. W. Cooke, who seconded the amendment, asked for some information concerning the shares sold, and he expressed the opinion that the Directors should tell them what were the shares held by the Company.

Mr Peachcroft, in opposing the amendment, remarked that personally he was not altogether in accord with the Directors. There were one or two matters which were not satisfactory, but they must not forget that all the shareholders had an interest in common, and that was the benefit of the Company. He thought that the previous speaker was right in saying that they should know something about the shares. He urged the shareholders not to pass the amendment put forward by Mr. Dunnill. Starting on a new year, and having eliminated from the head of the concern many things which were detrimental to the interests of the Corporation, was it wise, he asked them, to undermine that by appointing a committee of investigation? That would mean ruin, and he urged them not to vote for the resolution. With reference to the issue of £100,000 second mortgage debentures, the speaker asked how the Company would stand in the event of a liquidation, and what would be the position of the income bond holders?

Mr. G. Herring (chairman of the Electric and General Investment Company) said that it was not worth while to talk of how they became acquainted. The Board of the Electric Construction Corporation put it roughly something like this: "We want a little straightening up; we think an independent investigation would do us good, and that you are in a position to do that and give us advice." Well, they (the Electric and General Investment Company) laid down certain conditions, which were accepted; previously they had had no business relations or financial dealings. They, therefore, entered into the examination perfectly impartially. It was not possible to make public the report which had been drawn up, but if any shareholder were to read it he would not sell his shares, but would buy more. There had been some mistakes, and the report pointed them out, but with good management and a small outlay the Company should do well. Then, having got the reports and the figures before them, his Board drafted the present scheme, which he explained. He assumed that the £100,000 would produce a 10 per cent. manufacturing profit; if so, that would pay back the £100,000, and the shareholders ought to be gainers thereby. To put the matter more plainly: If the percentage of the £10,000 is earned, it is that £10,000 which pays back the £100,000, and yet the £100,000 still remains in the business. Though the scheme had been commented upon in the newspapers, counsel regarded it as perfectly [illegible]. He thought that success was certain in future with good management, and he advised the Board to let their motto be "More and more and still more economy." To the shareholders he said, "Don't change your Board now just at the time when you are emerging into prosperity."

Mr Millington observed that one of the members of the Board was connected with two or three companies now in liquidation. He thought the shareholders should know the name, as it might influence their votes. He referred to Mr. Dibley, whom he asked whether he would retire from the Board.

Mr Dibley said that he would retire from that or any other Board if there could be in the slightest sense, anything brought against him in connection with his being on the [illegible] General Bank. He could not think of resigning at the [illegible] of one or two persons, as that would be passing a vote [illegible] upon himself as if he had done something wrong. When [illegible] came out in connection with that bank, they would [illegible] that he was not to blame.

Mr Hancock supported some of the remarks made by Mr. Millington.

Dr Drysdale suggested that Mr. Dunnill should withdraw the amendment, as he thought it could not be carried. He was one of the shareholders who had visited the works at Wolverhampton, and he regarded them as the first and most extensive of the kind in this country.

The **Vice-Chairman** considered that it would be very detrimental to the interests of the Corporation to give to the public a list of the shares they held in subsidiary companies. They were, he might mention, held in 10 companies. The shares were [illegible] securities, and no bank would give such information [illegible]. If, however, the shareholders would apply at their offices, they would there be shown the list and be given full particulars in each case.

Mr H. Brown (the solicitor) remarked that the income bonds ranked next to the preference shares in the event of liquidation. In that case the document looked as if the income bonds would exist as well as the second mortgage bonds, though that was not the intention when it was drawn up.

Mr Herring said that when the deed was drawn up it was not the intention that the income bonds, in case of liquidation, should exist together with the second mortgage bonds; they were only to come into existence after the latter had been redeemed. If the matter could be put right, they were anxious that it should be done.

The **Solicitor** was of opinion that the matter could be arranged.

Mr Dunnill then commenced to again read his amendment, but was interrupted by cries of "Withdraw."

The amendment was then put to the meeting, with the result that only five shareholders supported it. It was therefore not carried.

Mr Dunnill then said he should demand a poll, but the **Solicitor** informed him that according to the articles there could be no poll on a question of adjournment of a meeting or the election of a chairman.

The original motion was then put and carried without any dissentients.

Mr Dunnill then demanded a poll on that, but this was objected to by the shareholders generally. This request was however withdrawn on its being shown that the Board had a large majority (7,179) in proxies, and Mr. Peachcroft had 3,000, without including the rest of the meeting.

Mr. James Pender and Mr. John B. Verity, the retiring directors, were separately re-elected, as were also the auditors, Messrs. Brodie, Paterson, and Co.

The assembly came to an end with the usual vote of thanks to the Chairman.

COMPANIES' REPORTS.

WOODHOUSE AND RAWSON UNITED, LIMITED

Annual report of the Directors and statement of accounts for the year ending July 31, 1892.

The Directors, in submitting their report upon the balance-sheet for the year ending July 31, 1892, desire to express their regret that the favourable expectations which they entertained at the commencement of the year, and which they expressed in the last annual report, have not been realised. In common with almost all undertakings connected with electricity, your Company has felt severely the competition of the past year arising through the depression of trade, and this depression has told with especial heaviness on this Company because, acting on the manifest and frequently expressed desire of the shareholders that the [illegible] side of their operations should be developed, the Board has, within the last 18 months, formed branches in the chief centres of electrical enterprise throughout England and the Colonies. Many of these, as, for example, Sydney and Johannesburg, after the initial losses incident to their formation, have developed into promising undertakings, but the benefits likely to be derived from them do not show in the last year's balance-sheet. The result of these developments has been shown by the fact that whereas the

turnover of the industrial portion of the Company's business was, in the first year, £72,258, that of the second year was £126,015, and that of the year just concluded £151,121. On the other hand, the financial portion of the business, which has been repeatedly stated to the shareholders to be the most profitable, has, owing to the financial depression, been almost entirely suspended during the past year. In most of the Company's branches there has been a loss more or less serious, due to a large extent to the unfavourable period which succeeded their formation. Owing to the number of these branches the aggregate of such losses would in any case have proved large, but some are so considerable as to require special notice. The failure of the arrangement for continuing the manufacture of incandescent lamps under the license of the British Electric Lighting Company, obliged the Board during the past year to close down, at any rate for a time, a large portion of their Cadby Hall factory, which had been laid out for the purpose of this part of their business, and has also obliged them, as they are no longer at liberty to sell their lamps in the United Kingdom, to write down the value of their large stock by 75 per cent., the sale price of lamps abroad being only one-fourth of that realised in this country. Their valuable lamp plant has also depreciated largely from the same cause, as it cannot be utilised before the expiration of the Edison and Swan patent in November next. This has been one of the most serious blows to the progress of the Company, but one which may be retrieved when they recover at that date the right of using their valuable patents, which have gained for the Woodhouse and Rawson incandescent lamp an established reputation throughout the world. The Board would point out another serious disappointment in the industrial department during the past year. When the Directors last met the shareholders they had obtained a valuable concession for lighting a large area of the richest part of Paris, and had entered into an agreement whereby they had secured the co-operation of one of the strongest firms in France, who undertook to provide over one-half of the capital required. This would not only have provided a large profit by the sale of the concession, but would have furnished employment for the Company's works for some time to come. But owing to the insuperable difficulty experienced in raising the required balance of capital in this country, the advantages accruing to this Company by the concession were lost. The newly-acquired Kidsgrove and Chiswick works have also been the source of unexpected losses. In the latter case the Board have reduced expenses to a mere nominal amount The loss on the Kidsgrove works was mainly incurred in realising the assets and carrying out the contracts taken over from the vendors. These contracts are now finished, and the works have been placed under capable management; they require only a sufficiency of capital to enable them to carry on an important and profitable business. The remainder of the loss is largely due to the large amount written off for depreciation of stock, which had been increased in the expectation of a demand which, unfortunately, did not arise. The union of Cadby Hall and Manchester under one management has proved most unsatisfactory; the Directors have therefore recently placed the works at Manchester under the separate management of tried and experienced officials of the Company, and are reducing the business at Cadby Hall works to the execution of contracts in hand and actual orders, with a correspondingly large reduction of staff and standing charges. Notwithstanding, however, the serious check received by their industrial department through the causes above mentioned, the Directors consider that the Company would have, to a great extent, recouped itself by the results of its financial enterprise, if the past year had presented any opportunity for launching an industrial company with a reasonable prospect of success. The Oncken Company, which their contract with the patentee obliged them to bring out by the 1st August, yielded only shares as the profit of this Company, and these do not appear in the present balance-sheet. The Epstein accumulator, which was introduced by this Company, has proved a complete success as the most efficient and economical on the market. The Epstein Electric Accumulator Company, in which this Company is so largely interested, has been manufacturing now on a commercial scale for the past six months, and the result of its operations has been to demonstrate that the Epstein accumulator has solved the difficulty of using accumulators for traction purposes. Owing, however, to the general financial position there has been no chance of realising the value of the Epstein patents, but it is expected that this Company will derive large profits from them in the future. The Directors are glad to be able to state that the reputation of the Company is such that inventions of the most valuable description are constantly placed in the Company's hands for development, a share of the patents being given for their services in this respect, and without any money payment on their part. During the last 12 months the Board have given unceasing attention to the reduction of expenses, and they are glad to be able to state that their efforts have been successful. It is anticipated that a considerable further reduction will be effected within the next three months. The Directors have relinquished their fees since last January. The Directors regret to say that Mr Philip Rawson was ordered by his medical adviser to abstain from all business for a time, and resigned his seat on the Board in September last; Sir Edward Thornton also at a recent date requested the Directors to accept his resignation. Your Directors have not filled up the vacancies occasioned by these resignations, for they have felt that it was due to the shareholders that the appointment of Directors should be such as might commend itself not merely to the Directors themselves, but to the general body of shareholders. The auditors, Messrs. Jackson, Pixley, Husey, Browning, and Co., retire in accordance with the articles of association, and offer themselves for re-election.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY, LIMITED.

Directors: Grosvenor Talbot, Southfield, Burley, Leeds (chairman); George Henry Crowther, civil engineer, Huddersfield; Robert William Eddison (John Fowler and Co., Leeds, Limited), engineer, Leeds; Robert Hudson, engineer, Gildersome Foundry, near Leeds; Samuel Ingham (Illingworth, Ingham, and Co.), timber merchant, Leeds; Arthur Greenhow Lupton (Wm. Lupton and Co.), cloth manufacturer, Leeds; John Thomas Pearson, Melmerby Hall, Thirsk.

Report of the Directors and statement of accounts to be presented to the ordinary general meeting of the Company, on Wednesday, the 28th December, 1892, at 2.30 o'clock.

A freehold estate in Whitehall road, Leeds, immediately behind the Great Northern Railway Station Hotel, containing upwards of an acre, admirably adapted for the Company's purposes, and having the advantage of a river frontage, has been purchased. The property includes several workshops and other buildings which are not at present required by the Company, and from which a rental is being derived. The erection of works has been vigorously pushed forward, but it has been found impossible to complete them as soon as was expected, and it will probably be early in the coming year before they are in operation. Underground culverts, about 10,000 yards in length, for the reception of distributing cables, have been laid, and the drawing in of the cables is now in rapid progress. An arrangement was made with the Highways Committee of the Leeds County Council, for the necessary trenching to be undertaken by their staff, by whom the work has been admirably and expeditiously done. The applications for supply of current already received are sufficiently numerous to lead the Directors to anticipate a successful business for the Company. The whole of the present Directors having been appointed under article 77, their appointment will require confirmation by the shareholders. The retiring Directors, Mr. Grosvenor Talbot and Mr. Robert William Eddison, being eligible, offer themselves for re-election. Mr. John Gordon, jun., offers himself for election by the Company as auditor.

Gulcher Thermopiles. —The new Gulcher thermopiles made by Pintsch, of Andreasstrasse, Berlin, are being somewhat extensively used for chemical laboratory and commercial purposes, a very convenient means being thus afforded of obtaining small currents by the simple turning on of the gas. The following details are given: No. 1, 26 elements, 1.5 volts, internal resistance 0.25 ohm, gas $2\frac{1}{2}$ cubic feet per hour, price £4 5s.; No. 2, 50 elements, gas 4.6 cubic feet, 3.0 volts, 0.50 ohm, £8; No. 3, 66 elements, 4.4 volts, 0.65 ohm, gas 6 cubic feet, £9. 10s. The efficiency of these thermopiles is greatly superior to any previous types.

BUSINESS NOTES.

Falmouth is still enquiring of companies on the cost of electric light.

Llandaff.—The Court-room at Llandaff is still lighted by candles only.

Holborn.—The Holborn Board of Works intend spending [illegible] on lighting the Town Hall by electricity.

Hampstead.—The Hampstead Vestry have decided to undertake the supply of electricity in the parish.

Western and Brazilian Telegraph Company.—The receipts for the week ended December 16 were £3,387.

Norwich Telephones.—The Thanet Telephone Company intend to open a service in Norwich at the New Year.

Wimbledon.—The inhabitants of Wimbledon are again taking up the discussion of a scheme for electric lighting.

Walsall.—The Walsall Town Council have resolved to [illegible] ask the South Staffordshire Tramways to extend their line.

South Staffordshire Line.—The actual opening of the line has been postponed to next week, in order to have the [illegible] cars ready.

Kingswood.—The question of examining the [illegible] appliances throughout the district has been referred to [illegible] Committee.

St Pancras.—The St. Pancras Vestry has decided to [illegible] plans and estimates for an extension of plant for 25,000 [illegible] 16 c.p. lamps.

Magdeburg.—The contract for lighting the quays at Magdeburg has been given to the enterprising firm of Messrs. [illegible] Co., of Dresden.

Edinburgh.—The deputation from the Edinburgh Town Council appointed to obtain information on electric lighting has been in London inspecting various central stations this week.

Elmore's French Patent Copper Depositing Company.—Warrants have been posted for the 10 per cent. dividend on the preference share capital for the half-year ended November 1.

West India and Panama Telegraph Company.—The receipts for the half month ended December 15 are £2,511, as compared with £2,544. The August receipts, estimated at £3,921, realised £3,947.

Plymouth.—The Works Committee say they have no intention of introducing the trolley system as yet, but have [illegible] powers in case experience demonstrates the success of [illegible] traction.

Claybury.—The tender of Messrs. Appleton, [illegible] Williamson, of Queen Victoria street, at £[illegible] for [illegible] fittings at Claybury Asylum, has been accepted by the [illegible] County Council.

Accumulators.—We have received the price-list [illegible] S. Phillippart fils et Cie. of the Faure-Sellon-Volckmar [illegible] newest types are well illustrated. The office of the company [illegible] 26, Rue de Chateaudun, Paris.

Embankment.—The London County Council have deposited [illegible] General Powers Bill, in which, among other things, powers are sought for the lighting of the Victoria embankment and [illegible] and Westminster Bridges by electricity.

Partnership.—The following appears in the *Daily News*: "To scientific gentlemen. Wanted, a partner (sleeping or otherwise) in an exceptionally promising undertaking of a [illegible] nature. Apply for further particulars, 912 L., *Daily News* Agency Office, 67, Fleet street, E.C."

Mechanical Pumps.—The most interesting exhibit at the recent Mechanics' Fairs at Boston was that of the Boston Vacuum [illegible] and Electrical Company. Incandescent lamps are exhausted by a mechanical vacuum pump, having a capacity of 376 lamps at a time, at the rate of 5,000 a day.

Crompton and Co., Limited.—The Directors have declared interim dividends for the six months ending September 30 last, at the rate of 7 per cent. per annum on the preference shares of the Company, and at the rate of 5 per cent. per annum on the ordinary shares, payable on the 21st inst.

City and South London Railway Company.—The receipts for the week ending December 18 were £918, against £[illegible] for the corresponding period of last year, or an increase of £[illegible]. The total receipts for 1892 show an increase of £2,071 over those for the corresponding period of 1891.

Rawdon Foundry Company, Limited.—This company has been registered by Jordan and Sons, 120, Chancery lane, W.C., with a capital of £2,000 in £10 shares. Object: to carry on the business of mechanical and electrical engineers in all their respective branches. Registered without articles of association.

Heckmondwike.—The Heckmondwike Local Board have resolved by six votes to five, one member being neutral, to apply to the Board of Trade for consent to carry out a scheme for lighting the town by electricity, and to apply for the sanction of the Local Government Board for borrowing powers in the matter.

Scarborough.—About £10,000 capital has already been subscribed for the Scarborough Electric Lighting Company, and the directors have gone to allotment. The whole of the machinery and plant is on order, and Mr. Campbell Swinton, the managing director, hopes to begin building immediately after Christmas.

Chelsea.—Mr. Brass considers the electric lighting [illegible] Chelsea, driven by power obtained from the destructors, would be

£6,000. Estimates are to be submitted. Mr. Brass considers that the Vestry should also deal with the whole question of private lighting in the manner that the St. Pancras Vestry have done.

Leeds.—It will yet be a few weeks before the permanent plant is complete in Leeds. Meanwhile, by special arrangement, certain of the customers are being supplied till after Christmas by temporary plant. Pipes have been laid in all the principal streets and the cables are being drawn in, over eight miles of cable having been placed in position.

African Overland Telegraph.—It is understood that Mr. Rhodes will personally urge on the Egyptian Government his proposal to link Egypt with South Africa by telegraphic cable. He has left London for Paris, to proceed *viâ* Brindisi to Egypt, and subsequently will leave in a German East African Company's steamer for Mozambique.

York.—The Corporation have received some 15 tenders for a first installation of a central electric light installation for the city, and are now considering which it is to their interest to accept. The introduction of the electric light into the city in connection with the new Courts of Justice, police, and other offices has been a satisfactory introduction of the light.

Telephonic Alarm Stations.—The Cardiff Watch Committee on Monday decided to establish a series of telephonic alarm stations throughout the town. The precise number and situation of these telephonic stations was left over until the borough engineer should submit to the committee an ordnance map of the borough, indicating where the head constable proposed to put the stations.

Weston-super-Mare.—The Electric Lighting Committee of the Weston-super-Mare Commissioners consider that the electric lighting scheme should be left over until the question of a refuse destructor is settled. The instance of St. Phillips was mentioned, where a 40-h.p. engine worked from the destructor generated electric light. The surveyor will present a report on the subject.

Eastern Telegraph Company, Limited.—This Company announces the payment, on January 13 next, of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares, for the quarter ending December 31; and the usual interim dividend of 2s. 6d. per share on the ordinary shares, tax free, in respect of profits for the quarter ended September 30.

Madras Tramways.—Mr. Digby, the chairman of the Madras Tramway Company, has visited Madras, and it is understood that the encouragement accorded makes him hopeful that the whole of the capital required will be subscribed. The statement of the prospects of the company, says the *Indian Engineer*, reaffirms the conviction that it will prove remunerative and constitute an excellent investment.

Blackpool Tramways.—A special meeting of the Blackpool Town Council was held last week, the Mayor presiding, when a statutory resolution approving of the application for a provisional order for the construction of further tramways was carried. A recommendation that all the members of the Council visit Helsby, near Warrington, in order to inspect the "Brain system" of closed conduits for electrical tramways was adopted.

General Electric Company.—With reference to a supposed rumour that the firm of Smeeton and Page were partners, or otherwise controlled by the General Electric Company, this latter company wish to make it distinctly understood that there is no relation whatever between them, except that of ordinary business customers. It has been the consistent policy of the company to supply goods only, and not to tender for erecting work.

National Telephone Company.—A circular has been issued by the committee of the Sheffield Telephone Subscribers' Association calling attention to the form of agreement which the National Telephone Company is submitting to its local subscribers. The circular says: "As the agreement at present stands, it is one which leaves out of consideration altogether the interests of the subscribers, being drafted entirely from the company's point of view."

Greenock Exhibition.—We regret to have stated, by an association of ideas that can be understood, that the lighting of the Greenock Exhibition was carried out by Messrs. Paterson and Cooper. The arrangement was carried out, under the able management of Mr. W. B. Esson, by the Gulcher Electric Light Company, the engineer in charge at the exhibition being Mr. James Hollingham. The lighting has been very successful, the football matches by electric light being greatly appreciated.

Edinburgh.—At the meeting of the Edinburgh Town Council last week a deputation was selected to visit various towns and obtain information on the subject of electric lighting. The following are the members of the deputation: The Lord Provost, Bailies Steel and Walcot, and Messrs. Kinloch Anderson, Sloan, Mitchell Thomson, and Williams. It seemed, owing to the fact that eight members were suggested, that there would be a vote on the matter, but the necessity for a division was obviated by Bailie Macpherson withdrawing his name.

Yarmouth.—A largely-attended meeting of the members of the Ratepayers' Association was held on Wednesday last week at Yarmouth. The chief debate was upon the adoption of the Corporation of the electric light proposals, involving an expenditure of £15,000 to £20,000. In an animated discussion the action of the majority of the Town Council was condemned. A deputation was appointed to wait upon the mayor, asking him to convene a public meeting to discuss the subject. The mayor has intimated that he would grant the use of the Town Hall, provided a requisition, signed by 25 well-known ratepayers, is handed to him.

South African Exhibition.—The Executive Committee of the South African and International Exhibition have now made known the result of the jurors' investigations. The following gold medals have been awarded to Messrs. Mather and Platt, Limited, of the Salford Iron Works, Manchester: (1) For dynamos for electric lighting and electrical transmission of power; (2) for electric lighting plant; (3) for incandescent lighting plant; (4) for motors. We are also informed that Messrs. John Davis and Son, of Derby and London, have been awarded the following medals—viz.: Two gold, three silver, and one bronze for the following exhibits: Electric light fittings, incandescent electric lighting, safety lamps, surveying, drawing, and engineering instruments.

Barnet.—The Barnet Local Board seem decided at last to go properly to work for the establishment of a central electric lighting station in their district. They have applied to Prof. Robinson, who, as Mr. Schmidt said, was very well known in the electrical world, and one of the best men the Board could get, having carried out the St. Pancras lighting, the most successful central installation yet erected. Knowing the district, his fee would be 25 guineas for a report on the cost of the scheme. The chairman remarked it would be a matter for the future to decide whether the Board should carry on the installation or delegate their powers to a contractor. The chairman and Mr. James were appointed to meet Prof. Robinson and go round the district with him.

Westinghouse Lamps.—The Westinghouse Company has announced the price of its new separable lamps: 35 cents (1s. 5½d.) for 25 and 20 c.p. lamps, and 30 cents (1s. 3d.) for 16, 10, and 8 c.p. lamps, with discounts of 2½ to 10 per cent., according to quantity. The allowance for the return of the globes to the factory will be 10 cents each, so that the net price of the 16, 10, and 8 c.p. lamps, which form the greater proportion of those used, will be only 17 cents (8½d.). The net price of the 20 and 25 c.p. comes out at 21½ cents (10¾d.) each. The efficiency of the 50-volt lamps is placed high, 2½ watts per candle being mentioned. It is claimed that the saving to a central station by the return of the globes and the low prices may be as much as nearly 1 per cent. dividend on the shares.

Telephone Charges.—At the meeting of the Newport Harbour Commission last week, Messrs. E. P. Jones and Son sent a long letter with reference to the proposals of the Post Office to charge conversation for the use of all trunk telephone lines after January 1. They thought the system was a wrong one, and asked for the expression of the Board's opinion. Mr. Heard proposed that the Board support the action of the Associated Chamber of Commerce in endeavouring to induce the Post Office to substitute rentals for conversation fees. Mr. Ward spoke against the motion, and thought that the fee system would be the better, although it might give persons who used the trunk lines a little more trouble. The chairman thought it would be a great deal more trouble. The motion was agreed to.

Andaman Islands Telegraph.—Mr. John Eliot, meteorological reporter to the Government of India, says the *Indian Engineer*, while approving of the laying of a telegraph cable to Port Blair, doubts whether Government would deem it advisable to incur the necessary outlay (some 15 lakhs of rupees) until the port authorities of Calcutta take the initiative by laying a cable from the Eastern Channel lightship to Saugor Island. This would enable the light-vessels and pilot-vessels to be effectively warned of the character of all approaching stormy weather, and give at least six hours' earlier definite information to the port authorities in Calcutta of the intensity of storms approaching the mouth of the Hooghly and the port of Calcutta. In our opinion, adds our contemporary, both cables are desirable if not absolutely necessary, and we trust that both the Government of India and the port authorities of Calcutta will take speedy action in the matter.

Haslingden.—At the Haslingden Town Council meeting last week the chairman (Councillor Barlow), on behalf of the subcommittee, reported that in accordance with the instructions of the committee, the sub-committee appointed to gather information relative to the electric lighting had visited Nelson, and as a result of enquiries made there they waited upon Mr. Barton, electrical engineer, of Blackburn, relative to the putting down a plant and the supplying of electric light to the public street lamps and the tradesmen of the borough, etc. The sub-committee made arrangements with Mr. Barton for him to visit Haslingden, and furnish them with a report upon the electric lighting of Haslingden. Mr. Barton's report was read to the committee, and after some discussion thereon it was resolved that the report of the committee be received and adopted, and that the report of Mr. Barton be printed and forwarded to each member of the Council for their consideration.

Bolton Tramways.—A special meeting of the Bolton Town Council was held on Monday, when the principal business was a discussion in regard to the proposed application for parliamentary powers to permit of the Corporation operating the tramways themselves, and borrowing the requisite funds for so doing. A large majority of the Council were favourable to the proposal on the grounds that the Corporation ought to safeguard its position by this power; that it would popularise the tramcar service, economise it, and improve it, and secure better working conditions for the tram employés. It was also suggested that, seeing the Corporation are contemplating adopting electricity, that they ought to be in a position, if necessary, to adopt it to the tramcar service. It was contended, on the other hand, that there was no need to obtain the powers suggested, seeing that the trams were already efficiently managed, and that it was possible the Corporation might not avail themselves of the privilege if they secured it. The proposal to obtain powers was, however, carried by 30 votes to 5.

Cardiff.—A meeting of the Electric Light Committee was held on Tuesday, the Mayor presiding. The town clerk read a draft agreement between the Corporation and Mr. Massey, as consulting engineer, at the remuneration of 5 per cent. on the outlay. The agreement was ordered to be signed. Mr. Massey stated he had been instructed, with the borough engineer, to prepare plans and specifications for the central station, so that the Local Government Board inspector might come down. A building twice the size needed was provided, and allowance for extra mains, the total cost being about £32,500. The station would be equal to all requirements for six years, and the chimney for 12 years. After a brief discussion it was agreed that the estimates be adopted, and that the necessary steps be taken for obtaining the sanction of the Local Government Board for borrowing the money. The borough engineer was instructed as soon as this has been done to advertise for tenders.

Windsor.—The Windsor and Eton Electric Light Company which has just laid down its mains at Windsor was summoned on Monday before the borough magistrate for breaking up the streets without the permission of the Town Council, which had been refused in consequence of the company having failed to satisfy the Board of Trade that it was able to fulfil the duties and obligations conferred upon it by the provisional order. Mr. C. H. Long, the town clerk, prosecuted. The engineer in carrying out the works had displaced 4,711 square feet of pavement, and the company, which admitted its offence, had by its breach of the local regulations rendered itself liable to maximum penalties amounting to upwards of £1,182. The Bench, however, took a lenient view of the matter, and inflicted a fine of £2 and another of £9. 18s., the latter sum representing a halfpenny a foot for the area of pavement disturbed. The company also had to pay the cost of the proceedings, which, however, were inconsiderable.

Ogmore.—On Monday, Tynewydd and Nantymoel, in the Ogmore Valley, near Bridgend, were lighted by electricity for the first time. The ceremony of switching on the current took place simultaneously at half past six, being performed at Tynewydd by Mrs. Williams, wife of Alderman Williams, chairman of the company, and at Nantymoel by Mrs. D. Sims Rees, wife of the vice chairman, in the presence at each station of a number of the directors and shareholders. The lighting is on the incandescent low pressure continuous current system, and the public lamps are of 16 c.p. The current is generated at each station by two compound wound and self regulating dynamos worked by a duplicate expansion engine of a nominal 35 h.p. There are two reserve dynamos, and each machine is capable of supplying 200 lights each. The light has been adopted in nearly all the principal shops and buildings, and proved a great success. The whole of the work has been carried out by Mr. G. Wilson, electrical engineer, of Aberdare, and the undertaking belongs to a limited company.

Fleetwood.—At a meeting of the Lighting Committee of the Fleetwood Commissioners on November 29th, it was recommended unanimously that the clerk be authorised to obtain from Messrs. W. H. Preece, F.R.S., and T. L. Miller, their terms for proposed services as electrical advisers upon tenders already received. The report upon proposed electric lighting at Yarmouth and other towns was read. On December 7th the committee again met. A communication was read from Mr. T. L. Miller, consulting engineer to the Bootle Corporation, stating his fee for going through the tenders received and advising the committee would be 35 guineas. The other gentleman who had been asked had given his fee as 50 guineas. Mr. Nicholson asked if they were far enough ahead to spend 35 guineas? The chairman said they were at a standstill now. Mr. Shuttleworth said this was information they would be compelled to get sooner or later. The chairman said that Mr. Miller was an independent gentleman, and his advice would be valuable. He had been recommended by Mr. George Curwen, of Liverpool, Mr. Allsop, of Preston, and others. Mr. Shuttleworth made the remark that "the charges of London experts were extravagant," after which it was decided that Mr. Miller be appointed electrical adviser.

Poole and White, Limited.—Under the winding up of Poole and White, Limited, a statement of affairs was issued on Monday by the Official Receiver. The gross liabilities as to creditors are returned at £23,293, against which £10,104 was expected to rank for dividend. The estimated net assets, therefore, stand at £11,885. As regards contributories the total deficiency is £16,082. The Company was registered in February, 1890, for the purpose of acquiring and carrying on the business of Poole and White, electrical engineers, of Broad street. The nominal capital was £20,000, divided into 3,400 ordinary and 600 deferred shares of £5 each. Debentures to the extent of £11,000 were issued since February, 1892, the consideration being, it is stated, cash in all cases. The failure of the Company is attributed generally to insufficiency of capital. The creditors appearing as fully secured are stated to hold a mortgage on the uncalled capital of the Company. "It may be noted," says the Official Receiver, "that the whole of the assets have been put beyond the reach of the ordinary creditors within the last 12 months, except in the case of one of the fully secured creditors, whose mortgage for £1,000 is stated to have been given in 1890."

The Cable Service to Australia.—The representatives of New South Wales, Victoria, South Australia, New Zealand, Tasmania, and Western Australia (says the *Times* of Monday) have signed, on behalf of their respective Governments, an agreement with the Eastern Extension Telegraph Company increasing the charge upon Australasian telegrams by 9d. per word, *i.e.*, making the rate to Australia 4s. 9d., instead of 4s. per word, which was the amount paid last year under the guarantee arrangement entered into between some of the colonial Governments and the company, under which the rate was reduced from 9s. 4d. to 4s. per word, the loss being equally divided between the two contracting parties. Up to the present the Indian Government had made no sign of abandoning their expressed intention of increasing the transit rate upon Australasian messages from 35 to 50 centimes per word. The Secretary of State has conveyed to the Indian Government the strong representations which the colonial Governments had made against the decision, which they regard as most unreasonable, [illegible], and unfair to the colonies; but, since no response has been made, it is thought that the Indian officials will be hard to [illegible]. As it was important that the changes of tariff should be brought into operation on the 1st prox., it became necessary to sign the agreement without waiting for a definite reply from India. The colonial Governments will continue to press their objections to the increased Indian transit rate, as they have placed on record that if it is insisted upon it will involve the colonies in very serious [illegible], and may lead to a return to the former high tariffs.

London County Council.—The Highway Committee report that the chief engineer has asked that Mr. H. W. Ridley, who was appointed on December 13 as an electrical assistant, may be formally appointed as an inspector under the electric lighting Acts and orders. The engineer states that Mr. Ridley is competent to discharge the duties of an inspector, and expresses the opinion that the work of the Council would be [illegible] should Mr. Ridley be appointed to the position. Compliance with this request of the engineer will not involve any alteration of Mr. Ridley's salary; and, as the committee think that advantage may result from such compliance, they recommend Mr. Ridley be appointed to discharge the duties of an inspector under the Electric Lighting Acts. The committee have considered a notice dated December 12, 1892, from the House to House Electric Light Supply Company, of intention to lay mains in Cresswell gardens. These mains will be laid in 3in. cast iron pipes, and the proposed works appear to be unobjectionable. They recommend that the sanction of the Council be given to the works referred to in the notice upon condition that the company do give two days' notice to the Council's chief engineer before commencing the works in any of the streets referred to in the notice; that no pipe of a larger diameter than 6in. shall be used; that the street boxes shall be of the pattern approved by the Council; and that, as an additional precaution against accident through defective insulation of the mains, each of the street boxes shall be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover shall be efficiently connected to earth.

Yarmouth.—At the meeting of the Great Yarmouth Town Council last week the committee recommended that the electric lighting of the town be proceeded with at once by the Corporation, that application be made to the Local Government Board for sanction to borrow the sum of £15,000 for the purposes of electric lighting, which would allow for 50 to 100 arc lights for street lighting, in addition to the 4,500 private lights, and that Mr. Preece be instructed to get out the necessary specifications for both street and other lighting, subject to a satisfactory arrangement as to fees. A letter was received from the Yarmouth Ratepayers' Association, urging the Council not to adopt the scheme for electric lighting. Mr. Martins moved the adoption of the report. Mr. Wiltshire thought there would not be a demand for even 4,500 lamps. They ought to start with [illegible]. An extension of time ought to be asked for. The price to be paid for specifications was far too much. Mr. Preece had been paid £50 already, and 5 per cent. on £15,000 would amount to £750. He thought they did not need Mr. Preece's services at that [illegible]. He moved the whole matter be referred back. Mr. Martins said the terms would come before the Council for approval. He gave particulars of success at Bath and Bradford, and thought Yarmouth was well fitted to have the light. The Mayor supported the amendment, but substituting, instead of reference back, that the resolution to proceed at once be omitted. This was [illegible], and Mr. Paston moved a further amendment that the instructions to Mr. Preece and his reply as to terms be submitted to the committee, with directions to draw up a report, and this amendment was carried.

Windermere.—At the monthly meeting of the Windermere Local Board, the report was considered of the committee appointed to consider upon what terms the Board should grant permission to lay down an electric cable through the Board's district. Mr. Irving said that the committee found that various difficulties presented themselves, the most vexatious of which was the uncertainty as to the agreement arrived at between Mr. Fowkes and the Bowness Local Board, by which the latter wished to ignore the Windermere Board altogether. Mr. Fowkes had promised to supply the clerk with a copy, but was cautioned to attempt to do nothing of the kind. An application to the clerk of the Bowness Board effected no better results, so that the committee were left entirely to their own resources in endeavouring to find out what had been done. They had visited Keswick, where they found the electric light was being supplied to private customers at the rate of 4½d. per unit, but not for public lamps, and the electricity was conveyed by overhead wires. During the greater part of the year the company were enabled to generate the electricity by water power at an extremely cheap rate. Since commencing, they had been able to declare a dividend of 3 per cent. on the outlay, with a reserve for exigencies. The cost of gas at Keswick was 3s. 4d. per 1,000ft., and the gas company were also paying a satisfactory dividend. Electricity at 6d. per unit was taken as representing gas at 3s. per 1,000. Mr. Irving then read the report, and after prolonged discussion proposed that it be received, and that the

extra cost of the electric light above that of gas being about £500 a year. The question of the Council acquiring the electric light undertaking from the company has been, as our readers are well acquainted, under consideration for more than a year, and various negotiations have been carried out, till at length it was decided to offer the company a certain sum of money for their works and goodwill. The Council have been practically unanimous in their action, one gentleman only being consistent in his opposition. Mr. Kapp was employed to report upon the matter, and his report was presented on the 3rd of May, and negotiations for the purchase of the company were carried on according to Mr. Kapp's valuation. The town has some 10 miles of streets, and the cost of laying down mains for the whole would be somewhat large. If only a few streets had that system, it would be scarcely fair to the rest. The streets were very well lighted now, and the Corporation wanted to extend the electric light as much as they could. A number of witnesses were then examined, the first of whom was Mr. Meyler, the town clerk, who produced the minutes of the Council, and gave evidence as to the general consensus of opinion being favourable, and that certain complaints were hardly warranted by the facts. The ex-Mayor also gave evidence of a similar character, in addition to which, however, he made a personal statement that he was a large user of the electric light and desired to retain it. The borough surveyor, Mr. J. H. Smith, said he had many deputations to see the electric light. He considered the present light much superior to the old system. They used to be "chaffed" a good deal about the old gas lamps. An alderman said a thief could escape if he stood under a gas lamp. There were 60 gas lamps removed when electric light was installed, and there were now 253 gas lamps and 36 electric. He made a report of the vibration complained of at the works, and considered there was no ground for the complaint. He received a letter that morning from a gentleman residing near the works, in which he said he found no vibration at all. There was a greater length of cable laid than streets lighted. By Mr. Clarke: There was something in the objection about the steam at the works. He was waiting to take over the works to remedy it. The cost last year of lighting the streets was £1,334. He had not calculated on the cost of lighting the whole streets with electricity. When they had gas the hours of lighting varied; some lamps were on all night. The electric light went off at three in the morning, as it was considered a waste to burn them longer. The cost of lighting by electricity was greater. In reply to a question of Major Cardew, he stated that the present cost of arc lamps was £22 16s. by contract, and the price was to be £25 per year. The chairman of the Lighting Committee (Mr. Henry J. Van Trump) gave evidence in perfect accord with that of the ex-Mayor. He stated that the electric light was one of the best advertisements Taunton ever had. Mr. Blakey, assistant electrician to the company, said the length of cables was 7½ miles. There had been an increase in the number of lamps installed of 491 in November last year against 917 this year. The latter had increased during the past few months. There were two private ones increased. Mr. Massingham had an installation lately of 120 incandescent lamps. The whole apparatus had worked more efficiently under the increased load, and the cost of coal had been less this year against £87 for November last year. The development of the work was hindered because there had been an insecurity of feeling as to the existence of the light. Dr. Fleming, who had been called in to make a report on behalf of the Laing, Wharton, and Down Syndicate, also gave evidence. He did not agree with Mr. Kapp in all his statements, and as regarded the cost per lamp for 50 lamps, he put it for each arc lamp at £28. The gas company naturally opposed the application, so far as we can glean, principally on the ground that it would be a disastrous failure in the future as in the past, and that loss would have to be borne by the ratepayers, instead of falling on the shoulders of the company. Mr. Kapp also gave evidence, and stated his reasons for not agreeing with the existing system. He gave an estimate of what the outlay would be for carrying out Dr. Fleming's plan, showing that there would be a loss of about £1,100. Other witnesses were called, and Mr. Pritchard shortly replied. A great many of the expenses, he said, that were mentioned in Mr. Kapp's figures would not be necessary, at least not until the incandescent lighting was extended. He (Mr. Pritchard) admitted that the Council would want a large capital beyond the £9,000 for the purchase. The cost of the current for arc lighting was considerably less than the figure mentioned by Mr. Kapp, and in that way the working expenses would be reduced. There could be no doubt that the price, £9,391, was a very low one, taking into consideration that the Council were not only purchasing the works, but also the goodwill and all the customers ready to hand. He had to ask the commissioners to report favourably to the Board of Trade, and then Taunton would not only have the best supply of water, the best drainage, but also the best system of lighting. Sir T. Blomefield: I must say that they are the best lighted streets in Taunton I have ever seen. This concluded the enquiry.

PROVISIONAL PATENTS, 1892.

DECEMBER 12.

22780. **Improvements in the method of and apparatus for electrolysing aqueous solutions of salts.** John Ashton Heap, 15, Corinne road, Tufnell park, London.

22804. **Improvements in electric hair and skin brushes.** George Ive Spalding and Richard Leonard Hawkins, 34, Southampton buildings, Chancery lane, London.

22836. **Improvements in or relating to the constr[uction of] electric accumulators.** William Phillips Th[ompson,] Lord street, Liverpool. (The S[chlesische?] E[lektricitäts] Gesellschaft, Raab and Bastiane, Commandit schaft, Germany.)

22837. **A combined knocker and electric bell contact.** Septimus Hooker, 27, Martin's lane, Can[non street,] London.

22838. **Improvements in long-distance telephones.** Aubrey Day, 321, High Holborn, London. [(…] Marshall Haynes, United States.) (Complete [specifica]tion.)

22854. **A new or improved electric arc lamp.** He[…] Norfolk House, Norfolk street, Strand, Lond[on. (…] Archat, France.)

DECEMBER 13.

22858. **An improved electric arc lamp.** George Dav[…] John street, Adelphi, London.

22889. **Improvements in electrical fittings, also app[licable to] other purposes.** Arthur Firth and George [...]well, 15, Abbey street, Greenheys, Manchester.

22914. **Improvements in printing telegraphs.** W[illiam] Wise, 46, Lincoln's inn fields, London. (Char[les] Buckingham, United States.) (Complete spe[cification.)]

the spurs touched the horse's flanks the poor brute was noticed to act as if in great pain. As was but natural, the judges observed these actions, and enquiries made into the occurrence resulted in the jockey being disqualified for barbarous conduct. He was then ruled off the course.

An Electric Mail Car.—There has just been introduced in the city of St. Louis, Missouri, the first postal tramcar in the United States, and probably in the world. The car, which is on an electric route, traverses five miles in 35 minutes, during which it collects mail matters from carriers who are in waiting at 10 or 11 different stations, where also the letters are delivered which have been sorted on the car. By avoiding the old plan of sending all postal matter to a central office for sorting, a great deal of time is saved. In fact, one letter is reported to have been delivered 26 minutes after it was posted, and tradesmen and others are now expected to make use of the post to a greatly-increased extent for the rapid delivery of parcels and messages. The cost of the present experiment, carried out by the desire of the local postmaster, has been defrayed by the tramway company; but it is hoped that the United States Government will now take the matter up.

Distance Switches.—M. P. Simon, in *L'Electricien* for December 24, illustrates an electromagnetic switch for turning off lights at a distance. Two electromagnets, mounted at right angles, control two armatures, which are pressed back by springs in the usual way. One of these carries a triangular piece of metal, which, when one of the push-buttons is pressed, is pulled down, making contact between the two wires for the lamps; at the same time it becomes hitched in a catch on the other magnet armature, and so held in place. To turn out the light, the second button is pressed and the catch is released. Nothing can be simpler than the idea, and, says M. Simon, there are more advantages to be claimed for this kind of switch than at first appear. They allow all the switches to be fixed in one place, and, if need be, under one lock and key; the extra lengths of wire of the main cables or wires are not needed, as the switches can be fixed at the nearest point, and only a couple of small wires brought back; they allow a great control over the expenditure of current, thus reducing the running cost. In some circumstances such electric switches might certainly have a useful place.

High-Tension Discharges.—The long sparks from high-tension currents, 31in. between the terminals, which were produced by Prof. Elihu Thomson last April, have been greatly surpassed by the same intrepid investigator. Streams of sparks between terminals 64in. apart have been obtained, and even this great length was limited by the mechanical construction of the apparatus, and not by the limit of sparking distance. The torrent of bluish-white sparks differs little from the appearance of the shorter discharge, except in the development of lateral discharges, which leave the electrodes in all directions, forking through the air a distance of several feet, not always towards the opposite terminal. The curious part about this interesting experiment is that the transformer used had only 480 turns on the secondary in a coil 17in. diameter and 28in. long, immersed in oil, while the primary, which receives the condenser discharges, has 15 turns only. The sight of the successful taming of lightning flashes 5ft. long is in itself sufficiently extraordinary, while the possibility of obtaining such enormous potentials, though at present little more than a *tour de force*, may conceivably lead to very important results in practical work, in the same way that the explosive force of high-pressure steam has been tamed and applied.

High-Tension Transmission.—An installation of a type that will tend to multiply has recently been started in San Antonio Canyon, California. The installation is erected for the purpose of supplying Pomona and San Bernardino from San Antonio, where there is a fall of water 1,300 cubic feet per minute, with a head of [illegible] The water is brought to the power-house through 1,900ft. of 30in. and 600 24in. double-riveted sheet-iron pipe, which absorb by friction a head of 12ft. The power station is provided with four double-nozzle Pelton wheels 34in. diameter, coupled direct to alternating Westinghouse dynamos of 200 h.p. each, running at 600 revolutions. Two exciters are run by two Pelton wheels of 20 h.p. The current is transformed up to 10,000 volts, and carried on two No. 7 bare copper wires seven miles down the canyon to a point where they diverge, one running to Pomona, [illegible] miles, and the other to San Bernardino, 28 miles distant. The current is transformed by step-down transformers outside these towns to 1,000 volts, and distributed for both light and power purposes, the motors used being of the Westinghouse synchronous type. The sub-stations are provided with regulators, so that the attendants can regulate the voltage independent of the generating plant.

Lighting of Nelson.—On Friday last, in the presence of several members of the Nelson Town Council and other guests, the ceremony was performed of inaugurating the electric light installation which the Corporation of Nelson have just established in the borough. Alderman Hartley, chairman of the Gas Committee, formally turned on the switch, and during the proceedings it was stated that Nelson had achieved the distinction of being the first Lancashire town where the Corporation had completed a public electric light installation. The distributing mains are laid in the principal streets of the town and tradesmen have become guarantors for the use of about [illegible] lights, the cost of the installation to be wholly met by the consumers of the light. The Corporation have also placed a 2,000-c.p. lamp in the centre of the town, and it is intended to place a similar lamp in front of the market. The cost of the installation, which has been made by Mr. T. Barton, of Blackburn, has been about £4,000. The generating station is at the Corporation gas works, and the steam pressure of 80lb. required for driving the engines is supplied by waste heat from the retort house, thus economising the cost of working the installation. The engine and dynamo are capable of supplying electricity for 600 lamps for 16 c.p. each. The distributing mains are laid in iron troughs placed underground, the cables being of 61 strands, insulated. During the evening the streets where the electric illumination is supplied were traversed by a large number of interested spectators.

Mirror High-Tension Electrometer.—The electrometer of Herr Heydweiler, described in the *Zeitschrift für Instrumentenkunde*, is based upon the mutual repulsion of a sphere and a ring charged to the potential to be measured. In the hypothesis of a uniform distribution of electricity this effect is nil when the ball is concentric to the ring, and also at a great distance. If the sphere is passed from one position to the other along the axis of the ring, the effect increases to a maximum, to again diminish. In the position of maximum effect, the force is only dependent to a small extent on the distance between the sphere and ring. The instrument based on this effect is in the form of a torsion balance, the repulsion effect being double. Two rings are mounted side by side, into these protrude two arms carrying small spheres, the whole hung on a bifilar suspension, the arms being connected to a large centre ball. The size of the centre ball is 3.5 cm. diameter suspended by wires 01 mm. diameter and 9 cm. to 10 cm.

reduced speed of alternators; (4) their adaption to standard engine speeds; (5) all alternators self exciting and compounded; (6) alternators run in parallel; (7) carbon brushes on all alternators set at 80deg. to 90deg.; (8) alternators driven direct, even down to 100 h.p.; (9) one type of dynamo in central stations—said dynamo to render all kinds of service required; (10) higher primary voltages all round; (11) engines and dynamos regularly inspected by a company formed for that purpose. Mr. Watts's motto, in characteristic American vein, is: "Man wants but little here below, nor wants that little long—but during the short time he wants it, he wants it bad." There is much to be said both for the idea of low alternations and for standard dynamos whose current may be made—converted or redressed—to do every service.

Dynamo Driving by Compound Engines. — A paper on the efficiency of engines for dynamo driving was read before the October meeting of the Engineering Association of New South Wales by Mr. P. Diamond, illustrated with diagrams from actual engines. He quoted the article from *Engineering*, January 29, 1892, giving the difference in power required for electric lighting, citing Newcastle-on-Tyne, where the lightest load was 15,000 watts, and the heaviest 170,000 watts, or only 0·088. At the St. James's and Pall Mall stations, December, 1890, at 4 p.m. to 4.30 a.m., the load was 20,000 watts, and at 6 p.m. it was 400,000 watts. Putting the latter into horse-power, they would be respectively about 26 i.h.p. and 536 i.h.p. If only one engine is used this would mean serious waste, depending on the relative time the smaller power was required. The Westinghouse Company publish a table in their catalogue giving the consumption of steam per indicated horse-power per hour, with varying loads, which for non-condensing engines ranges from 170 i.h.p. with 21·9lb. steam, down to 50 i.h.p. with 28·8lb. of steam. Mr. Diamond then discussed the diagrams which, with one exception, were from engines at work in Australia. No. 1 was from a vertical non-condensing Corliss engine, at Saltair, and came into the writer's possession about 1869. The cylinder is 16in. diameter, 3ft. stroke, making 80 revolutions per minute, the power developed being 164 i.h.p. Other lines dotted showed a greater and smaller power—viz., 186 i.h.p. and 116 i.h.p. The consumption of steam calculated for these powers were 28lb. for 186 i.h.p., and 25lb. for the 164 and 116 i.h.p. The lowest power is 0·623 of the highest, while the lowest consumption of steam to the highest is 0·89. No. 2 diagram was from a horizontal non-condensing engine which had been at use at the Randwick tram-driving station. Cylinders 13in. diameter, 1ft. stroke, 300 revolutions, developing 91·69 i.h.p. The power given out by dynamo was 530 volts and 105 amperes, making 75·93 e.h.p., giving an efficiency of 0·828, assuming 10 per cent. friction of engine. This seems a very good performance. The consumption of steam as calculated is 38·8lb. steam. This engine would not have a great difference in the consumption of steam for varied powers, as the cut-off was effected on the compression side of the diagram. No. 3 diagram was from a horizontal compound non-condensing engine at Parliament House, used for driving the electric light. The cylinders are 9in. and 14in. diameter, ratio of 1 to 2·42, stroke 16in., revolutions 118. The power developed is, for small cylinder, 21·6 i.h.p., and for large one, 24·2; total power is 45·88 i.h.p. the dynamo gives 111 volts and 233 amperes, equal to 34·66 e.h.p., and the efficiency is 0·755. In this diagram the power was very fairly divided between the two cylinders, and, if 10 per cent. be allowed for friction, this would give about 23 i.h.p. to take off each, and they would then give good results. The amount of steam as calculated is 29·5, but tests made gave a much lower consumption. No. 4 diagram was from a pair of horizontal compound non-condensing engines at the Centennial Hall, used for electric light driving. The diagrams were taken on September 7, 1891. The cylinders are 13in. and 23in. diameter, stroke 2ft., revolutions 109; the power of small cylinder is 102·72 i.h.p., and of large one 49·04 i.h.p., total, 151·76 i.h.p. The output of dynamo is stated as 103,250 watts, equal to 138·4 e.h.p, and the efficiency is 0·91. If 10 per cent. is allowed for friction, then the power which the engine could give out would be reduced to 136·6 i.h.p., or about 2 i.h.p. less than that given off [illegible] dynamo. These engines use, as calculated, 92·5lb. steam. The distribution of power, when compared to No. 3, is [illegible] very good, as the small cylinder is doing two-thirds of [illegible] work. The diagrams showed considerable back pressure [illegible] large cylinders, which gets as high as 2lb. before compression commences. No. 5 diagram was off the same engine as the No. 4, but was taken on the 23rd April, 1892, under the normal condition of the present lighting requirements. In this case the small cylinder shows 66·9 i.h.p., the large one 11·6 i.h.p.; total, 78·5 i.h.p. The dynamo was giving off [illegible] volts and 236 amperes, equal to 32·44 e.h.p. The efficiency is 0·41. If 10 per cent. of No. 4 power be allowed, this would give about 7 i.h.p. for each cylinder, and as the large one indicates only 11·6 i.h.p., this leaves about 4·6 i.h.p. which this cylinder could give out, and is further aggravated by the fact that at 0·7 of the stroke the pressure commences to go down below the pressure required for friction, and ultimately lands below the atmospheric line. The back pressure is the same as in No. 4. The calculated consumption of steam is 43lb., so that at about half the load the consumption of steam has increased by [illegible] per cent. These figures bring out the particular objection raised against the use of compound engines with greatly varying loads, and the writer regarded it as fortunate that these particular engines were only doing about half the work they were intended for, thus illustrating where the trouble lies, so that the remedy might be pointed out, and the character of the compound engine saved. No. 6 diagram was from a pair of horizontal compound non-condensing engines at Circular Quay lighting station; the cylinders are 8in. and 14in.; stroke, [illegible]; revolutions, 87; power shown is for small cylinder, 19·7 i.h.p., and for large one, 11·7 i.h.p. The power given off for 28 arc lamps is 18·7 e.h.p., the efficiency is [illegible] and the steam consumption 31·4lb. No. 7 diagram was from a pair of horizontal compound non-condensing engines at the Redfern lighting station. The cylinders are 13in. and 23in. in diameter, stroke, 2ft.; revolutions, [illegible], the power shown in small cylinder, 56·5 i.h.p., and in large one 26·1 i.h.p.; total, 82·6 i.h.p. The dynamo gives off 1,0[illegible] volts and 41 amperes, equal to 55·5 e.h.p., the efficiency is 0·68, the steam consumption calculated 36lb. In this case again the distribution of power was unequal, but the diagram is entirely free from the defects in the large cylinder of No. 5; the only lights in use are the street lamps, so that there is practically no variation in the load, and diagrams giving a heavier output could not be had. No doubt when the house-lighting is secured, and used, different results could be had. The Centennial Hall engines were driving light and heavy loads, all the others were driving steady loads. The calculation for consumption of steam is by an approximate method suggested by Rankine in his "Steam Engine" (p. 409), and mentioned in Cotterill "On the Steam Engine" (p. 58), and although not strictly accurate, gives a means of comparing the efficiency in diagrams which show any variation in feature

FIELD MAGNETS.

BY GISBERT KAPP, M.I.C.E.

(Concluded from page 632.)

The magnetic force required to produce an induction of $\mathfrak{B}_a$ lines through the armature, Fig. 66, is $H_a = \frac{\mathfrak{B}_a}{\mu}$, where

$$H_a = \frac{\cdot 4 \pi X_a}{L_a}.$$

We have, therefore, $\mathfrak{B}_a = \mu \frac{\cdot 4 \pi X_a}{L_a}$;

and in order to determine X_a, the ampere-turns required for the armature alone, we must know the value of the permeability at the particular induction chosen. This can be found experimentally (as was first done by Dr. Hopkinson in connection with the design of dynamo field magnets) by testing the particular sample of iron used for armature plates and determining the permeability curve, or better still, the magnetisation curve, representing $\mathfrak{B}$ as a function of H. We know what total flux we require to give the desired E.M.F., and by dividing this by the area of the armature core we find $\mathfrak{B}_a$. Then, referring to the magnetisation curve we find the corresponding H_a. The ampere-turns required for the armature are then given by

$$X_a = \frac{H_a}{\cdot 4\pi} L_a$$

$$X_a = \cdot 8 \, H_a \, L_a.$$

In order to avoid the coefficient ·8, it is convenient to compile, once for all, a table from the magnetisation curve in which the values of $\cdot 8 \, H_a$ and $\mathfrak{B}_a$ are inserted. We have then only to refer to the table and find the number with which the mean length of the lines through the armature must be multiplied to give X_a. In other words, the numbers of the table give the ampere-turns per centimetre of the path which the lines take through the armature.

The following two tables (one for G.G.S., and the other for English measure) may be used when the armature core is composed of best charcoal iron discs.

Exciting Power in Ampere-turns Required per Centimetre and per Inch of Armature Path.

The use of these tables can best be explained by an example. Say that in the armature shown in Fig. 66 the average length of path is L_a = 11in., and that we desire to have an induction of B = 16·5. By referring to the table we find that 75 ampere-turns are required per inch of path, so that out of the total exciting power applied to the field magnets 11 × 75 = 825 ampere-turns will be required for producing the flux through the armature.

To determine that part of the exciting power which is required to drive the flux through the air space, we use formulas (35) and (36). The dimensions of the polar surfaces we take from the drawing of the machine, but it is important to note that the average area through which the flux passes is slightly larger than the polar area, since the flux spreads out into a fringe at the corners of the pole-pieces, as shown to an enlarged scale to the right of Fig. 66. In practice it is generally assumed that the total width of fringe may be taken as equal to the air space, and if λ is the length of the polar area, and l the length of the armature, the mean area of interpolar space is

$$A_a = l\,(\lambda + \delta). \quad . \quad . \quad . \quad . \quad (37)$$

The average induction in that space is

$$\mathfrak{B}_a = \frac{F_a}{A_a} \quad . \quad . \quad . \quad . \quad . \quad . \quad (38)$$

and the exciting power for the air space is

$$X = \cdot 8 \, \mathfrak{B}_a \, 2\,\delta \text{ and } X = 1{,}880 \, B_a \, 2\,\delta \quad . \quad . \quad (39)$$

There remains yet the determination of the exciting power required for the magnets, including pole-pieces and yoke. Here we are met by the difficulty that on account of magnetic leakage the flux is not the same in the different parts of the magnet circuit, and that the law according to which it varies is not accurately known.

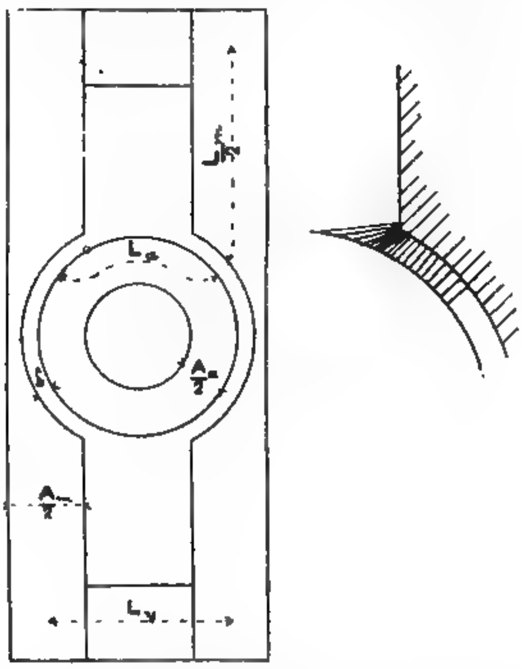

Fig. 66.

In Fig. 67 the leakage is roughly represented by dotted lines, but only those paths are shown which lie in the plane of the paper. In addition there are, of course, leakage lines between the side faces of the poles and between these and the yokes which come out of the plane of the paper in various directions, the whole machine being surrounded with a kind of magnetic halo. An attempt has been made by Prof. Forbes* to determine the leakage by assuming certain paths and integrating the flux over the various surfaces of the machine, but as in applying his methods a great deal must depend on the personal judgment of the calculator, it is generally found more accurate to calculate the leakage of a new machine from the experimental results previously obtained with machines of a similar type but of different size. Such experiments are easily performed. Referring to Fig. 67, we may assume with tolerable certainty that the flux will be a maximum at M, being in the middle of the excited part of the magnet circuit, and a minimum at A in the armature. We need then only place exploring coils round the magnet and armature in the two positions, and connect them with a ballistic galvanometer. We note the deflections on making and breaking the exciting circuit, and determine thus the total flux in these two points and their ratio. As a further check, we can couple the two exploring coils in series, and by reversing the connections determine $F_a + F_m$

* *Journal*, Society of Telegraph Engineers, xv., 551, 1886.

and $F_m - F_a$. Mr. Esson has published leakage tests made with various machines,* and has found that the ratio F_m F_a varies from 1 3 to 2. The leakage is thus represented for each type of machine as a coefficient, but such a way of representation cannot be correct for all cases, as will be seen from the following consideration. Suppose we have found a certain leakage coefficient when testing a machine with a moderately strong field. The same coefficient cannot possibly be right for the same machine if excited to a higher degree. Let us assume that we excite the machine so as to get 30 per cent more flux through the armature. The ampere-turns required for the air space have now increased by 30 per cent, but those required for the armature have increased by more than 30 per cent., so that the total magnetic pressure forcing leakage lines out of the pole pieces has increased in a greater ratio than the flux, and for this reason the leakage coefficient will now be higher. It is therefore more accurate to determine the leakage field not as a function of the total field, but as a function of the exciting power, $X_a + X_e$, actually applied to the armature. Since the leakage takes place through air, for which $\mu = 1$, the magnetic resistance of the leakage paths is constant, and we can find the total waste field, $\xi = Z_m - Z_a$ by simply dividing the armature exciting power by the magnetic resistance, ρ, of the leakage paths

$$\xi = \frac{X_a + X_e}{\rho}.$$

The coefficient ρ depends, of course, on the size and general configuration of the machine. A machine with

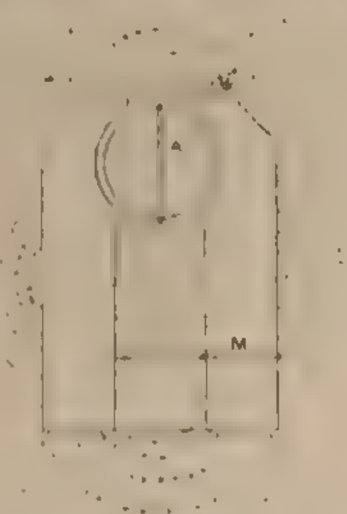

Fig. 60.

large exposed poles will naturally have a smaller ρ than one in which the poles are small. Thus Fig. 57b will have more waste field than 57d, the latter will have more than 57c, and this will have more than Fig. 59. Again, if we invert 57c so that the poles come near the bed-plate, the leakage will also increase.

We have now to consider what influence the size of a machine has on the leakage resistance ρ. By doubling the linear dimensions we quadruple the surfaces from which the leakage takes place, but at the same time we double the average length of the leakage paths so that the total leakage resistance will be halved. The leakage resistance for two machines of the same type will, therefore, vary inversely as the linear dimensions. A convenient way of stating the linear dimensions of a machine is to give the size of its armature, and in order to permit of slight variations in the ratio of length and diameter of armature, we may conveniently state the linear dimensions of the machine, not in terms of either the diameter or the length of the armature, but in terms of the square root of their product. The leakage resistance will then be given by the expression

$$\rho = \frac{K}{\sqrt{l\,d}} \qquad (10)$$

where l and d are the length and diameter of the armature core, and K is a coefficient depending on the type of the machine, but not on its size.

In overtype machines K may be taken at ·3 in C.G.S., and 680 in English measure, and in undertype machines at ·21 and 460 respectively. By adding the leakage lines to the useful flux we find the total flux through the magnets, and therefore the induction. To find the corresponding exciting power we proceed in the same way as with the armature, by the use of a table giving ampere-turns per centimetre or per inch as a function of the induction. There is, however, this difference, that an error in the estimation of the permeability of the armature core is not of very great importance, the exciting power required for the armature being, as a rule, comparatively small, whereas an error in the estimation of the permeability of the field magnets may be of great importance, as it affects a much larger part of the total exciting power. The difference in the permeability between various samples of iron is generally greater for high than for low inductions, so that if for constructive reasons we are compelled to work at a high induction in the field magnets, it becomes all the more important to test the magnetic properties of the particular brand of iron employed. On the other hand, there is less danger of error if we work with a moderate induction, a course which we would adopt wherever possible with a view to economise exciting wire. In such case the exciting power required for the magnets is relatively smaller, and an error in this smaller quantity is of less importance—to say nothing of the fact that the error itself is not so likely to occur. In ordinary work we may, therefore, neglect to test a sample of the metal in each case, and use a table of 𝕭 and $\frac{X}{L}$ prepared, once for all, from tests made with iron of average quality. The usual materials for field magnets are wrought iron, cast steel, and cast iron. The latter should be only employed for those parts of the circuit which are not surrounded by exciting wire, such as yokes and pole pieces, because, otherwise, the cost of copper owing to the large sections of iron surrounded by wire becomes too great. Wrought iron and mild cast steel are generally used for the magnet cores proper, and are about equivalent, magnetically.

Exciting Power in Ampere-turns Required per Centimetre and per Inch of Path through Wrought Iron.

Out of 13 samples of cast steel which I tested in the magnetometer, three only were of sensibly lower permeability than ordinary wrought iron as used for cases

* Journal Inst. Electrical Engineers, xix., 122, 1890.

the nearest number of B is 5, to which correspond 4·85 ampere-turns per inch of path Interpolating, we find that to B = 5·10 correspond 4·95 ampere turns, and as the average length of path of the lines through magnets and yoke is 66in., the magnet exciting power is

$$X_m = 4·95 \times 66 = 326.$$

We now find the total exciting power by adding up its component parts. Thus:

The armature core requires	85	ampere turns
The air spaces require	5,042	,,
The magnets require	326	,,
Total	5,453	,,

The calculation here explained gives us, incidentally, also the leakage coefficient, but only for the particular flux of 500 lines. We have seen that 163 lines are wasted over and above the 500 utilised. The percentage of waste is therefore 163/500 = 32·6 per cent., and the leakage coefficient is 1·326.

To find other points on the characteristic, we repeat the calculations, assuming a flux of, say, 800, 1,000, 1,100, 1,200, 1,300, 1,400, 1,500, 1,600, and 1,650 lines. These calculations may be conveniently made in tabular form, so that clerical errors may be more easily detected and labour economised. At the head of the table we write the constructive data of the machine to facilitate reference.

$A_c = 80$ $A_a = 335$ $A_m = 130$ $\rho = 31·5$
$L_c = 16$ $\delta = ·9$ $L = 66$ $2\delta\,1,880 = 3,384$

Z_a ξ Z_m	B_c B_a B_m	X_c X_a —	— $X_c + X_a$ X_m	— — X
500 163 663	6·25 [illegible] 5·10	8·5 504·2 	— 5,127 326	— — [illegible]
800 261 1,061	10 2·385 8·17	136 8,100 —	— 8,236 543	— — 8,779
1,000 328 1,328	12·5 2·98 10·20	210 10,100 —	 10,310 680	— 10,990
1,100 364 1,464	13·75 3·29 11·23	313 11,150 	 11,463 780	 12,243
1,200 402 1,602	15 3·58 12·31	515 12,150 —	 12,665 942	— — 13,607
1,300 [illegible] 1,748	[illegible] 3·83 13·44	1,000 13,150 —	— 14,150 1,290	- 15,440
1,400 516 1,916	17·50 4·18 14·7	2,075 14,170 —	— 16,245 [illegible]	— — 18,315
1,500 594 2,094	[illegible] 4·48 16·1	3,520 15,200 -	— 18,720 4,880	— — 23,600
1,600 691 2,291	20 4·775 17·6	5,600 16,200 	 21,800 11,550	— 33,350
1,650 [illegible] 2,420	20·6 4·92 [illegible]	7,600 16,650 -	— 24,250 21,300	— - 45,550

If we now determine the leakage coefficient for a flux of 1,500 lines we find it to have risen to 1 + 594/1,500 = 1·394 For Z = 1,600 it is still greater—namely, 1 + 691/1,600 = 1·432, whilst the initial value was only 1·326 It will be thus be seen that the leakage coefficient can only give the approximate value of the waste field. Fig. 68 shows the characteristic as plotted from the above table. By the use of this curve we can at once read off the exciting power required to produce any desired flux through the armature within the limits of its capacity to pass the flux. The E.M.F. produced being proportional to the flux and the speed, we see that the curve, by suitab[ly ...] the scale of ordinates, may also be used to repre[sent the] E.M.F on open circit for constant speed as a fun[ction of] the exciting power. It is, however, important to [...] that the curve only refers to the E.M.F. on ope[n ...]

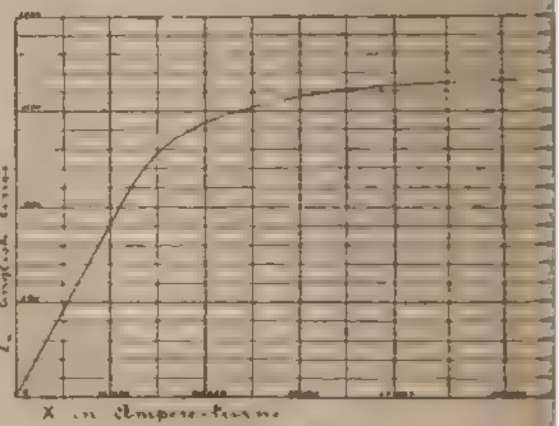

FIG. 68.

If a current is permitted to flow through the arm[ature it] produces a certain reaction on the field, and this [must be] taken into account.

PROPOSED ELECTRICAL CONGRESS AT CH[ICAGO]

A sub-committee formed of Prof. Ayrton, F R S , P[rof.] Thompson, F R S , and Major-General Webber, C B M I C E , has issued a report to the committee of [the elec]trical section After a brief historical account of [the] Congress of 1881, the report continues

Subjects on some of which it is proposed that al[so] suggestive special papers might be read by specially [...] members Comparison between procedure in [...] countries. Methods of avoiding electrical interfere[nce ...] risks to person and property. The committee suggest that it would be desirable [...] selection should be made as soon as possible, by the A[...]

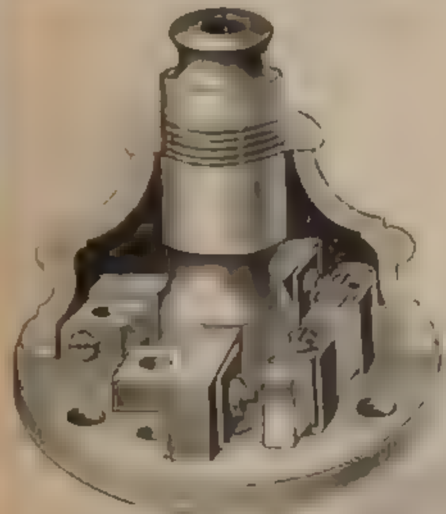
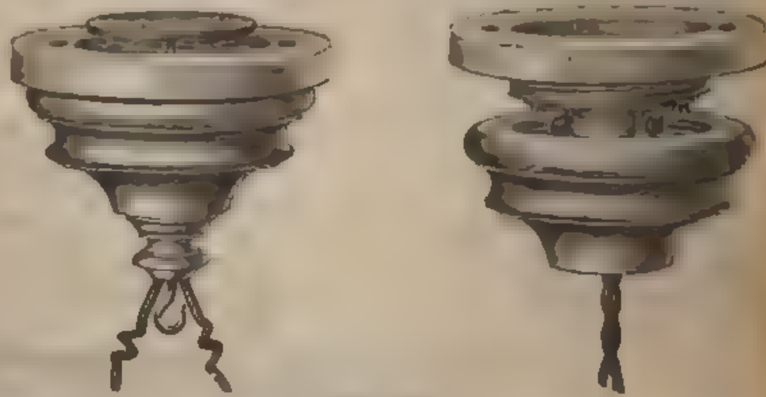
desired. The same cut-outs are made in conjunction with other fittings, such as switches or ceiling roses. One of the illustrations shows an improved form of ceiling rose with centre support to carry the weight of an electrolier. It has raised sectional bars of china on the base with removable

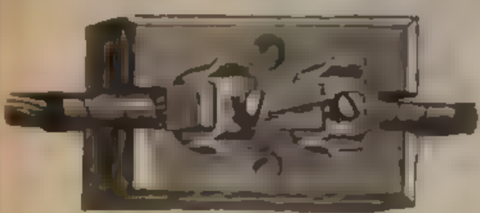


Ceiling Rose with Bar Cut-Out

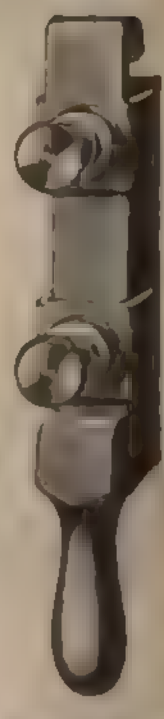


Ceiling Roses

Lever Bar Switch Cut-Outs



China Bar Cut-Outs

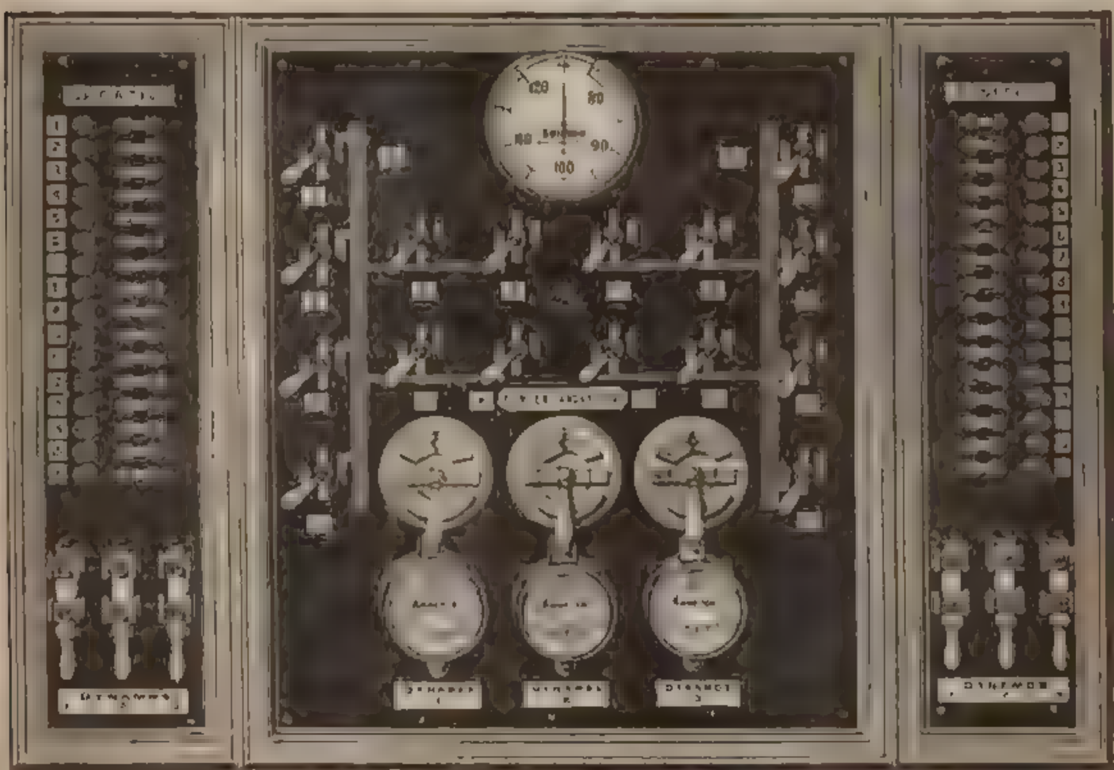


bar cut-out, and the cap is fastened by a screw collar. Other types of screw-covered ceiling roses are made, with or without a central hook for taking the weight of the lamp. The ornamental switches for houses are made in a great variety of very handsome designs, the floral decoration of cream china in harmonious shades touched with gold being favourite forms.

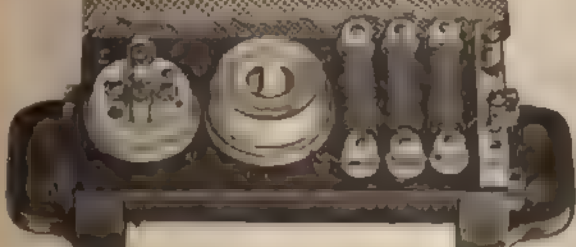
The accompanying illustration is reproduced from a photograph of the main switchboard erected at the new post office at Birmingham. The board is of slate, enamelled black, measuring 7ft. 6in. by 5ft. 4in., enclosed in an oak frame, and mounted on substantial supports. The mains from three dynamos are led to the lever switch cut-outs on the right, the current then passing to the ammeters and main switches. These latter are designed to carry 100

amperes, and consist of massive gunmetal castings mounted on heavy slabs of porcelain. These are two-way switches, so that the current from any dynamo may be sent to either set of eight branch switches, but by inserting a plug between the contact-pieces of any switch, the current is distributed to all the 16 branches. The arrangement has been found of the greatest advantage in changing over, as lamp on an incandescent circuit. A patent extra-rapid double-pole main switch is also illustrated, of somewhat peculiar make. Two discs of hard fibre carry a pair of semi-circular brass plates, and revolve under the action of a powerful steel spring. This is released by the action of the ratchet handle, and the movement is so rapid that it cannot be followed by the eye. There are a

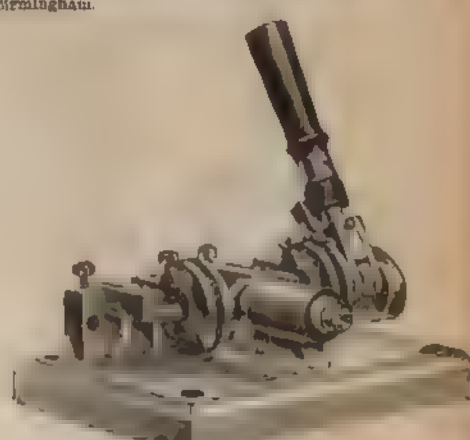
Ornamental Screw [illegible] Switches.



Dynamo Switchboard, made for the New Post Office, Birmingham.



Switch, Fuse, and Resistance.



Extra Rapid Break Switch.

the load may be transferred to another dynamo in two stages. From the 16 switches the current travels to the positive cut-outs on the right, thence to the distributing switchboards on different floors in the building, returning to the negative cut-outs on the left, and, finally, through the negative main lever switch fuses back to the dynamo.

A very convenient piece of apparatus is a bar fuse, switch, and resistance frame on one base for an arc large variety of other china fittings made by Messrs. Fowler and Lancaster too numerous for us here to illustrate, especially among counterweight pendants, roses, wall contacts, and some neat and effective forms of lamp holders. For these we must refer readers to the descriptions published, issued from their works at Graham-street, Birmingham, in which the china fittings are fully illustrated.

LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom...........	3s. 3d.	6s. 6d.	13s. 0d.
Other Places...........	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. IX. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding obtained, price 2s.*

ELECTRICITY AND RAILWAY MANAGEMENT.

The short days of winter and the great amount of travelling necessary for all business men, bring prominently forward the question of lighting and heating our trains. It is usual to contend that only long distance trains need consideration, but we maintain that as much attention should be given to the comfort of the suburban passenger as to the comfort of the long-distance passenger. A very large proportion of the illness in the winter season is caused by the disgraceful and condemnable system of railway management. Thousands of men and women daily leave warm homes and offices to walk to the station. Physically, on arriving at the station, they are in the best of health, and comfortably warm. But something has delayed the train, and in the majority of cases they have to wait on a wind-swept platform without a chance of shelter, thereby incurring the danger of a chill. Even if the train is, as the Americans say, "on time," the compartment into which they are hurried is several degrees lower in temperature than the rooms which they have left, and often we hear the remark, "Yes, I caught it—the cold—in the train." Travelling in winter in and around big towns is a dangerous pastime, especially in the evening, when a large part of mankind has not dined and is physically weaker to resist the effects of cold. So much for the lack of heat. The lack of light is perhaps less dangerous to health, but more active upon temper. If we have to wait about in railway stations and in trains, surely plenty of light might be provided. Specialists say reading in trains is bad for the eyes; lots of things are bad for health; but custom is strong, and reading in trains is common. It is ten thousand times worse for the eyes to read in a bad light than in a good one. The oil lamps provided deserve cursing instead of blessing; they serve not as aids to while away the time, only as aids to get into and out of carriages without knocking against the other occupants of the carriage. Here and there the railway companies have installed a better light. Some of them use gas, and turn it down as low as they can, while able to say it is a light. Others, and by far the greater number of trains, use oil with lamps that, either by means of a layer of oil which has escaped, or owing to construction, prevent more than a fraction of the light reaching the occupants of the carriage. Latterly, a few trains on some of the more progressive lines have been fitted electrically.

The whole question is said to be one of cost. This might be denied with a fair amount of accuracy, but we prefer to argue it on other lines. Travellers of a quarter of a century ago could tell a doleful tale of the management of some of the lines which at the present day are conducted upon different principles. Then everything was bad—the share quotations worse than all. Then, as now, the pessimists said, We cannot do this, we cannot do that; look at the cost, and we really have not got the money. Well, the pessimists were sent to Coventry, or some other place, where their moanings had no effect, and enlightened men began to

view of showing that, contrary to the general supposition, it is the employés—the staff—who reap the profits, and only in a few cases do the proprietors or shareholders of the concern employing them.

If anyone will take the trouble to examine the question, it will be found that, with rare exceptions, it is the old, long established businesses that are reaping profits, where profits are made. Businesses whose conductors, after weathering the storms of their early days, have learned not to go in for heroics, not to touch work that will not pay, except for very special reasons, such as a very certain road to a very profitable deal. They have learnt to examine carefully every project which comes before them, and to count the cost to its utmost, not to go into it blindfold because there was a taking look about it. They have learnt, too, that a certain rate of profit must be obtained if their businesses are to be a success, and will not be induced by the roseate views of any middleman to lower their prices below their working standard. They have learnt also, probably from bitter experience, that under the very ablest management their working expenses must be heavy. The very march of science, and the improvements that are constantly being made in electrical apparatus, render the expenses of the electrical engineer heavier, whether he be manufacturer or contractor, or both. Some new discovery may render a lot of apparatus worth only its value as old metal. There have been numerous instances of this within the last 10 years. The career of the alternator, for instance, affords a striking example.

After the first Paris Electrical Exhibition, when the Jablochkoff candle was thought to have solved the problem of electric lighting, and when even arc lamps of the ordinary type were being arranged to run with alternate currents, alternators were all the rage. Even so able a man as the late Count du Moncel, in reporting on the recently invented De Meriten's machine, referred to the fact that it was an alternator, as distinctly in its favour. Much capital was expended in developing alternators, and many different types were brought out, few of which are to be seen to-day. A short while after the alternator, in its then form, was a drug on the market. Later on, after the invention of the incandescent lamp, it came to the front again, but in quite another form, and again disappeared, and this after very large sums had been expended on it. Very few alternators of this second period are now working, they having been displaced by the compound machine. At any rate it would be a difficult matter to sell one to-day. Now the alternator is in the field again, but in yet another form as far as the manufacturer is concerned.

Anyone who held alternators at either of these periods when their sale closed, would have lost heavily on them. In all these cases it is the manufacturer or contractor who loses, not the engineer. The latter receives his salary as long as his employers have any money to go on with, and usually gets full credit for whatever he may have done, so that if he is really an able man he has usually not much difficulty in getting another appointment. The writer wishes it clearly to be understood that he in no wise underrates the services of engineers. But for their skill and ability the work usually could not go forward at all, and, again, they are able to reduce the losses made or to increase profits, when they do come, by that same skill and ability. What the writer wishes to do in this article, is to disabuse the minds of many engineers of the idea that they are not being fairly dealt with by employers, whom they think are taking the results of their labour and giving them short commons in return. He would also like to dissuade them from the idea that is constantly before many of them that they will do much better in business for themselves, and with that view save from their salaries, with a view of taking the first opportunity of becoming their own masters. The money that has been fairly earned, and perhaps represents years of careful living—perhaps accompanied by many privations—is too often lost in a few months by the possessor having been tempted into a "good thing." Once the money is locked up in machinery, or in a connection, for practical purposes it is gone. The owner of the machinery must stick to it like the galley slave to his oar, or a far harder taskmaster than the galley driver will soon be down upon him.

As an engineer simply, with a good know[ledge of his] work, he can go where he likes, his brain[s are] worth their market value, where the machinery [he may] have bought with the earlier fruit of them may [have to be] sold for old metal. The fortunes that have [been made,] except in cases where special circumstances have [helped,] have been made either by persistent, never tiring [work] continued over a very long period, or by some [clever] finance—some lucky speculation. It need hardly [be men]tioned here that speculation is not business, [accord]ing G. Sims's witty definition of business. A[nd] speculation is a very dangerous game for an e[ngineer to] play. Few men ultimately reap success from [it,] and the man whom Nature has intended for [an engineer] has smaller chance than anyone.

Men, too, who ought to know better, o[ften cry out] against the price charged for electrical appara[tus. They] estimate, sometimes correctly and sometimes [not, what] the cost of construction should be, and they [add what] they consider ought to be a fair profit on it, and [this] is what in their opinion the price of the article [should be.] Anything which is charged above they consi[der extortion,] and if the article happens to be one essent[ial to a par]ticular branch of the industry, they declaim th[at the price] is stopping its development.

The writer remembers an engineer telling h[im] of a particular branch of business. "We put on [...] for general charges and 25 per cent. for pro[fit," said the] writer's friend, "and we lost money." The ex[planation of] this was, of course, that the whole amount, an[d] more, was swallowed up in working expenses. [The writer] was pleased to find that the Electrical Se[ction of the] London Chamber of Commerce were discussing [the question] of cutting tenders for contracts, and he trusts [some]thing may be done to reduce that evil. He w[ould cite] another case similar. Edison Swan lamps, as is [well known,] are sold to the trade at a certain price, less a d[iscount. As] the trade seller has to pay carriage, to pay for t[he] empties and for breakages, this discount is ofte[n] absorbed; and under favourable circumstances [leaves] a very small margin. Yet there are many [in the] trade supplying lamps at a discount off the pu[blic price] and paying all these charges.

The writer would ask, Is there any reason [why] the consumer with this amount? or is it a su[fficient reward] for all the trouble of dealing with the party [and keeping] the account, that you have deprived someone [else of the] honour of doing so?

Is it not time that manufacturers and oth[ers ceased to] make handsome presents to consumers in the f[orm of discounts] to keep others out of the field? Will, also, e[ngineers in]tending to go into business for themselves be w[ise? Of] course they will not; they do no good to the[mselves;] they not only lose the money they embark in [the "good] thing," but they decrease the fund from which [their] salaries are paid, and so doubly injure themselv[es.]

ECONOMIC POSSIBILITIES OF THE GE[NERATION] OF E.M.F. IN THE COALFIELDS, [AND ITS] APPLICATION TO INDUSTRIAL CENTR[ES.*]

BY R. B. THWAITE, C.E.

(Concluded from page [...])

APPENDIX.

Specification of [...] h.p. Electric Power Transm[ission from] the Yorkshire Coalfields to the Metropolis [...] (1[...] miles).

C. E. L. Brown, of Brown, Boveri, [...]

Power Generating Plant.—Twenty Otto [...] 500 h.p. to 600 h.p. each, arranged so that when [...] working at their maximum load, and the whole [...] required, there are still three engines in reserve [...] to be 180 revolutions.

Electric Generating Plant.—Twenty triphase alt[ernate cur]rent machines, each for 600 h.p., together with [trans]formers, for stepping up the current to [...] generating machines would be regulated by [...] governors, and so arranged that there is one [...] electric generating machine capable of governing [...]

* Paper read before the Manchester Association of [...]

to 273 h.p. The magnet wheel of alternator is 7·2ft. diameter, and contains 30 poles. The smaller 50 h.p. turbines are coupled direct to a four-pole exciter running at 375 revolutions per minute, providing a current of 150 amperes at 180 volts E.M.F. The exciters are arranged in parallel, and they are equipped with hand rheostats. The regulation is effected by two automatic rheostats, of the Blathy type, in the field circuit of the exciting machines. These rheostats are so arranged that the E.M.F. of the 16 transformers working in parallel form a group that transforms the 5,000 volts pressure current into one of 2,000 volts, and transmits the current from the Tivoli aerial conductors to the underground network of conductor cables that distribute the electric energy throughout the streets of Rome. The effect of loss in the line is balanced by an equaliser. Switching out the main, and breaking the circuit is effected by the use of a load resistance rheostat, composed of 87 miles of iron wire. The transmission conductors consist of four copper cables of 19 wires each. The cables are so arranged that they can be exchanged at will in the event of accident, or when repairs are necessary. Three of the cables are sufficient for conveying the total energy of the generating station. Two wires carry two thirds of the load. The total efficiency is 80 per cent., or a loss of 20 per cent., the exact loss being stated to be 1,020 volts out of an initial pressure of 5,100 volts. The transmission cables are attached to very strong oil insulators, placed upon iron and wood poles erected at distances of 115ft. to 130ft. apart. The same line of poles carries a dozen bronze wires for telegraphic and telephonic purposes. The lowest cable is 25ft. above the ground. The central station in Rome, 18⅓ miles from Tivoli, is operated at a pressure of 2,000 volts, the Tivolian potential energy being reduced to this pressure by cable resistance, and 32 transformers, each of 25,000 watts capacity. At present 250 arc lights are in use, but this number can be increased up to 600. These lights are arranged in series of 45 each, the conductor aerial lines being of copper wire, four millimetres in diameter. Each large step-down transformer provides a current of 14 amperes at 2,000 volts for each group of 45 arc lights. Fourteen such transformers feed 14 arc light circuits, or 630 lamps. In each of these circuits the automatic rheostats establish a constant-current potential of 14 amperes.

The Cost of Electric Motor Generators Compared with that of Steam and Gas Engines.

It may be interesting and useful to compare the relative cost of the three methods of generating power—that is, with a steam engine, a gas engine, and an electric motor—from the point of view of the consumer, and based on German practice as interpreted by Prof. Salomon and Herr Redner.

In German small power steam engine practice of the non-condensing type, four kilos. of coal are absorbed per indicated horse-power—that is 8·80lb., and for the larger powers the average may be taken at 2½ kilos., or 5·50lb. per indicated horse-power per hour. Working 1,800 hours per annum, and using town's lighting gas for driving gas motor, it is found that up to 15 i.h.p., driven with this comparatively costly gas, gas engine power is the cheapest; but the margin of advantage gradually falls until for 25 i.h.p. it disappears, and is then only equal to steam; but where the time worked is 3,000 hours per annum, the gas engine is the cheapest form of motor generator all along the line. With electrically conveyed dynamic energy, the absorption of work need only be in proportion to work done, whereas with the steam engine the full load is always on. Herr Redner has established the cost of completely installing a line of motors varying in power from 1 h.p. to 25 h.p. It may be stated that the cost exceeds English practice, but the ratios are, however, usefully comparable.

Power of Motor.

	H.P. 1	H.P. 10	H.P. 15	H.P. 25
Steam engine—				
Marks	1550—£75·9.	M6800—£333.	M8300—£406.	M12000—£636
Gas motors—				
Marks	1810—£88·6	M6300—£308.	M8200—£401.	M10200—£501
Electric motors—				
Marks	650—£31·8	M2100—£102	M2520—£123	M3980—£195

In the cost of maintenance, including the yearly expense involved in repairs, interest, and amortisation, the electric motor generator is very much less than either that of steam or gas. Here are Herr Redner's figures:—

Motive Power.

	H.P. 1	H.P. 10	H.P. 15	H.P. 25
Steam engine—				
Marks	242·50—£11·88	M1020—£49	M1215—£60·9	M1800—£88
Gas motors—				
Marks	271·60—£13·3	M945—£46	M1230—£60	M1530—£75
Electric motor generators—				
Marks	105·14—£5·14	M350—£17·1	M440—£21·5	M575—£28

Herr Prof. Salomon is of opinion that for steam engines 5 per cent. should be allowed for interest, 8 to 9 per cent. for depreciation, and 1 to 3 per cent. for repairs.

It may be noted here that at Bockenheim the electric motors are hired out. The relative portable character of the electric motor and generator lends itself admirably for the convenient and often economically advantageous hiring out system.

Electric Traction.

One of the industrial applications that awaits fuller development is that of heavy electric traction for high speeds and long distances, and whilst locomotives with electric propelling gear are being built in both America and Europe of equal tractive power to an ordinary passenger steam-driven locomotive, a practical progressive step in the development of the application of energy exists in the South London electric railway. The ... of this underground addition to the metropolitan railway ... has removed any possible objections that could have ... against practicable electrically propelled locomotives ... exception of a few negligible minor difficulties, the ... has been a solid success, both financially, hygienically ... thermo-dynamical—the latter efficiency is 300 per ... than the ordinary locomotive practice. The following ... factors of experience in this application:

Running speed per hour, 13·25 miles.
Mean amperes from Stockwell to City ...
Do. volts do. do. ...
Mean amperes from City to Stockwell ...
Do. volts do. do. ...
Running speed per hour, 12·7 miles.

In these electric locomotives the armature coils ... directly on to the axles of the locomotive wheels, ... motives built by Messrs. Beyer, Peacock, and Co., ... chester, weigh 13½ tons. The original conception of ... method of driving is traceable to Sir W. Siemens ... currents are collected from a central rail by means ... contact shoe, fitted at each end of locomotive. ... torque, or starting energy, is 140 amperes.

Ordinary train driving by electric energy is in ... in the United States, and in its overhead conductor ... efficiency is said to be satisfactory. The same principle ... adopted by the Liverpool Overhead Railway. Underground ... electric traction is now successfully employed in ... Europe and America, and offers great advantages ... systems. The same principle of dynamic transmission ... for winding purposes. The traction of canal boats ... development to bring a wanted stimulus to this ... method of transmitting cargo.

The Financial Risk Involved in Laying Down Long ... Electric Conductors.

It will be recognised that for long-distance lines of ... the cost of installation and plant is made up in a very ... proportion by the electric conductor mains. Hence ... tion of the risk of value depreciation of this property ... class importance. TRADE NOTES AND NOVELTIES.

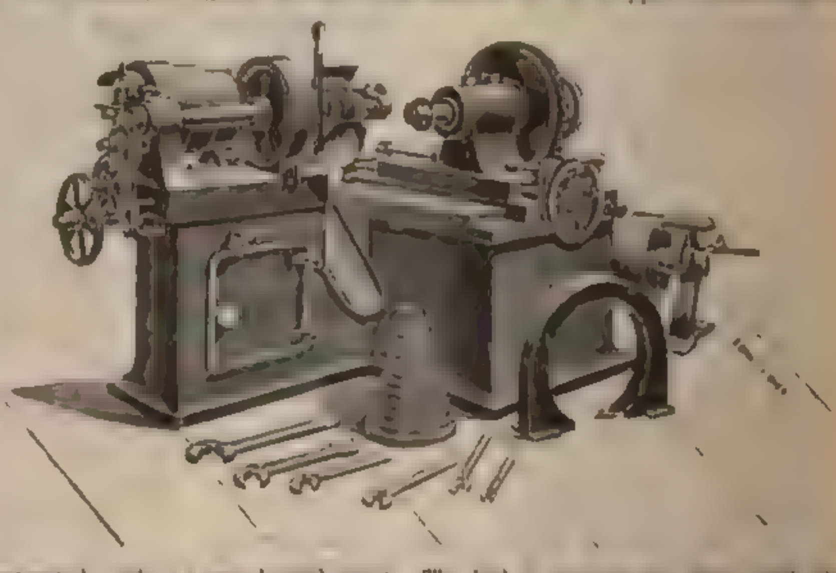
A NEW CIRCULAR MILLING MACHINE.

An important departure in the way of machine tools is now being introduced into this country by Mr. H. F. L. Orcutt, of 145, Cannon street, E.C., on behalf of Messrs. Ludwig Loewe and Co., of Berlin, and which is designed to a certain extent to take the place of the lathe for various turning operations, finishing as it does at one cut any circular surface that can be produced by rotating cutters. This tool, we are informed, can be used for finishing gear wheels, grooved pulleys, flanged pulleys, pulleys with crowning face, rope pulleys, rolls, hand wheels, balance wheels, and other work of this description. In many cases, it is stated, it produces work cheaper than turning by 50 per cent. to 75 per cent., as five or six of these tools can be attended by one unskilled operator, and they will do the work of double that number of lathes. With regard to the construction of the machine, of which we give an illustration, it may be noted that the cutter spindle is driven through back gears by a powerful belt, and the outer end of the cutter arbor is supported by an adjustable tail stock. The head, which carries the part to be milled, is very solidly constructed, and is adjustable in both directions horizontally, so it can be quickly set for different cuts, and it is firmly locked in place while the cut is being made. It is provided with adjustable stops. The circular feed of the working spindle, which is 23 in. in diameter, is driven by a worm which works into a large worm gear fastened directly to the spindle. This gives a steady powerful feed. The feed is variable through a set of change gears, and the whole machine can be stopped automatically at



any desired point. The bed is cast in one piece, with the inside arranged as a tool box. All the parts are thoroughly protected from dust. A set of change gears, necessary wrenches,

and countershaft are furnished with each machine. The size of tool illustrated mills parts from 4in. to 22in. in diameter. Mr. Orcutt, it may be added, informs us that a number of these machines, which are of a special class, made by Messrs. Loewe and Co., are now successfully at work in this country.

In view of the increasing importance to be attached to the growth of electric traction upon tramways, etc., and the consequent use of intermediate gearing, either single or double, between the motor spindle and the car axle, this machine ought to prove of value to manufacturing firms, as tending to give great accuracy in the gears, whilst also lessening the cost of production.

COMPANIES' MEETINGS.

EDINBURGH ELECTRIC SUPPLY CORPORATION, LIMITED.

The annual meeting of this Corporation was held at 17, St. Andrew-square, Edinburgh, on December 23. Mr. Walter Berry presided, and there was a good attendance.

The Managers (Messrs. George Dean and Co., C.A.) submitted the third annual report, the more important portions of which were to the following effect: In the second annual report submitted to the shareholders on December 23, 1891, it was shown that there were then 206 shareholders, representing a privately subscribed capital of £31,175, and there are now 212, with a privately subscribed capital of £32,775. Since last annual meeting the Directors have taken no steps to increase the share list by advertising or otherwise, as they consider that the nominal capital of £100,000 is fairly well secured, seeing that, in the meanwhile, only nominal holdings have been applied for, which will assuredly be greatly increased if the required concession is obtained from the Town Council. The interest taken in the electric lighting of Edinburgh is daily gaining strength, and there is a strong feeling in favour of supporting a financially strong and locally influential Corporation such as this, which the citizens of Edinburgh have themselves formed. On the 20th of July last the Directors minuted the following: "In consideration of the delay of the Town Council to proceed with the electric lighting of Edinburgh, the amount of the paid-up capital of the Corporation to date, namely, £1,561. 5s., lying in the banks, be invested in city bonds or consols, and instructed the managers to take the necessary steps to have this done. The Town Councillors have now recognised that the time has come when they must move in the matter of the electric lighting of Edinburgh, and, as may be seen by the reports of their meetings, they are proceeding with the matter as expeditiously as can be expected. Judging from present appearances, certain portions of this city will be lighted by electricity before this time next year, and the Directors have every reason to hope that this Corporation will be employed to carry out the work."

The **Chairman**, in moving the adoption of the report, said that when he addressed them on the occasion of their second annual meeting he said that they were unable to report any progress toward a definite realisation of the object for which this Corporation was formed. He had to some extent to repeat the same story that day, but with the satisfactory addition that their fate must very soon be decided, for the Town Council, which had to determine if it would undertake the electric lighting of Edinburgh on its own account or delegate the authority to others, had recognised that the operations to enable it to comply with the conditions laid down by the Board of Trade must be commenced forthwith, and they would have seen from the newspaper reports that the question in all its bearings was being anxiously considered. He did not think it probable that the Town Council would undertake the work themselves. They had plenty on hand, and were already overworked. He thought it most probable that they would entrust it to this Company, first, because of the local and unrepresentative position of the shareholders; second, because of their unquestionable financial power, and, third, because their shareholders would be the most important consumers, and would have a paramount interest in seeing that the work was well and substantially done, with as little disturbance to the streets as possible. Their interests and those of the Town Council were in many respects identical. They should, of course, look for a fair return for their capital and risk, but to a certain extent their Company might be considered as co-operative. He had no authority from his co-directors for giving an opinion, but personally he thought they were entitled to aim at 7 per cent. dividend on their shares. The Directors had never advertised for shareholders or offered founders' shares or any other inducements, but nevertheless applications had come in, and they had now on their list 212 names subscribing £32,775. The great majority of their shareholders had taken small preliminary holdings with the avowed intention of increasing their interest largely if the business was carried on, and he had no doubt that all the capital which they might choose to issue would be immediately absorbed when they were prepared to offer it. The Directors had met frequently during the year, and had given much attention to new developments in electric lighting both at home and abroad, and they were quite prepared, with the assistance of their consulting and acting engineers, to enter upon negotiations at any moment. He trusted that their patience would be rewarded, and that at their next annual meeting they should not only merit the congratulations of their shareholders, but the acknowledgments of a long-suffering public for thorough work performed. He would only add that they had as many conditional orders for installations promised as justified them in anticipating solid financial success.

Mr. John M. M'Candlish, in seconding the motion, said he was very glad to hear the hopes that were entertained of something coming out of this Company. He thought the inhabitants of Edinburgh were getting very impatient on the subject of the introduction of electric lighting. They were behind many inferior towns in this matter. He also thought the public would not view with favour the Corporation taking the electric lighting into their own hands, but would rather see them making suitable terms with a company such as this. Certainly no other company had anything like the claim that they had on the Corporation.

The report was adopted, and thanks were afterwards given to the Directors for their gratuitous services.

ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSITING COMPANY, LIMITED.

The third annual ordinary general meeting of this Company was held on Friday last at the Cannon-street Hotel, Mr. J. Jepson Atkinson occupying the chair. The notice calling the meeting having been read by the secretary (Mr. J. Sharmer),

The **Chairman** reminded the shareholders that the Company was a syndicate company, not for industrial operations, but for the sale of the foreign patents to companies. The assets therefore largely depended upon the success of the subsidiary companies so formed. During three years they had done well, and had paid back in dividends the whole of the priority share capital. At the end of last year the value of the assets was considerably higher than at present, but during the coming year the market value of the assets would materially improve. The Board intended to have the accounts for 1892 prepared immediately upon the expiration of the present year, and to meet the shareholders with the same not later than next February. The year 1891, now under consideration, did not see the formation of any new Elmore companies, and the year, as stated in the report, had been one of establishment and development of existing companies. After close and personal experience of the working of the companies since they last met, and notwithstanding the many seeming **failures and disappointments, he could assure them that the** coming year would be one of substantial prosperity to the manufacturing companies, from a shareholder's point of view. The Directors admitted that they had no doubt been too sanguine as regarded the length of time required to overcome the difficulties of starting and developing a new business, aggravated in one case by the smallness of the available working capital. These difficulties had, however, now been overcome, and the Elmore process to-day was, he said, perfectly successful from a commercial point of view. He was certain that the result would be a considerable improvement in their assets, and as a further consequence they would be able to dispose of other unsold patents. During the year they had had to largely assist the French Elmore Company financially, their advances to them being secured by mortgage at interest. The wisdom of that policy could not be better seen than by looking at the success which that company had achieved at its works. They had thereby secured an established value to their very large stake in the French Company in the form of shares and debentures, which would have been practically wiped out if any financial disaster had occurred to the French Company. The Directors would have been pleased to have declared a dividend of 100 per cent. to the priority shareholders, but, as stated in the report, they hoped to be able to do that in 1893. That was because he believed that the Elmore process was perfectly successful, and, consequently, with proper management, the companies would be successful, thus enabling them to realise their investments in cash. They had had only that week an offer with cash down for shares in the French Company, but it was too low and they had refused it. The Directors intended within a few weeks to publish the accounts for 1892. Now that the funds for the French Elmore Company had been arranged for, he believed that the value of the assets in the balance-sheet would be improved. He then moved the adoption of the report and accounts, which had been taken as read.

Mr. Macfarlan seconded the motion.

Mr. Inverarity moved that the accounts be not passed. He did not suggest that in any captious spirit, but in order that the rights and privileges of the priority holders should be discussed and laid down. He regretted that those privileges had been damaged by the Directors making large loans to the French Company, and which he considered as illegal and beyond the powers of the Directors. He then quoted from their articles to endeavour to substantiate that statement.

The **Solicitor** (Mr. Hays), in reply to Mr. Inverarity, quoted from the memorandum of association to show that the Company could lend to such persons on such terms as might seem expedient, and in particular to customers and persons having dealings with the Company.

Mr. F. L. Rawson then entered, in reply to various questions, into an explanation as to the reason for the advance made to the French Elmore Company. That company was "hard up," and the question was whether it was going to fail or not. If it had failed, all the companies would have done so. They therefore considered it advisable to lend the money, the security being a second charge upon the property after the £50,000 of debentures. The French Company had now managed to pull through, and arrangements had been made for the placing of the debenture stock, that company having received already £10,000 on that account. The output from the French works was between 10 and 11 tons per week, and that placed a value on the shares

which they did not have at the beginning of the year. He mentioned that people were coming over to purchase the Russian patents, and an offer made for the Belgian patents had been refused owing to its being too low. The shares in the Austrian Company would not be of any value to them until that company commenced to make a profit. Mr. W. Elmore, he said, had resigned, at the request of the directors of the English Company, so that he might devote his time solely to the Leeds works. In reply to a shareholder, he remarked that £35,000 had been received for the American patents, and that amount had been lent to the French Company, there now being only a balance to come from America of £200.

In reply to questions, the Directors promised not to lend any money or securities to other companies until the next meeting.

The motion was then put to the meeting, with the result that 28 voted for it and 22 against. The resolution was therefore carried.

Mr. F. L. Rawson, the retiring director, and the auditors, Messrs. Jackson, Pixley, Browning, Husey and Co., were re-elected, and the meeting closed with a vote of thanks to the Board.

FOWLER-WARING CABLES COMPANY, LIMITED.

Directors: Wm. Fowler, Esq., chairman; Walter Chamberlain, Esq.; R. W. Eddison, Esq.; George Fleming, Esq.; The Lord Medway; Geo. F. Smart, Esq.

Report of the Directors presented to the shareholders at the fourth ordinary general meeting held at the registered offices of the Company, Victoria mansions, 32, Victoria street, Westminster, S.W., on Thursday, the 29th December, 1892.

In submitting the third annual report, the Directors are pleased to call attention to the fact that, as they anticipated last year, there has been again an increase in the volume of business done as compared with the previous 12 months, with the result that this year a small profit has been earned. The Directors are satisfied that the business is steadily growing, and they believe that it will show continuous development with increasing profits as time goes on, more especially because a larger turnover reduces the average charge for general expenses, an item which is always disproportionately heavy in a new business; meanwhile, good orders in different departments have continued to come in since the 30th September. Some interesting details of the work done during the past year will be found in the annexed report of the general manager. As the shareholders have already been informed, the actual capital of the Company has unfortunately proved insufficient for its requirements, and the Board therefore, in May last, authorised an issue of debentures to the amount of £10,000. Of this sum £5,500 has been taken up, chiefly by the Directors themselves, after full opportunity of subscribing was given to each shareholder. This amount has sufficed for the present, but the employment of a still larger working capital will be necessary before any considerable development of the business can be suitably met. The Directors believe that such an increase would be justified by the results. Colonel J. T. North and Mr. R. S. Waring having ceased to be directors, Mr. Geo. F. Smart has been chosen to fill one of the vacancies thus occasioned. The retiring directors, Mr. William Fowler and Mr. George Fleming, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., offer themselves for re-election.

General Manager's Report. In reviewing the progress of the Company for the past year it is satisfactory to note an increase in the volume of business. The electrical industry, however, has not escaped the prevailing depression, and our turnover has not yet reached a figure which would fully employ the resources of the works and staff. A brief *résumé* of the principal work completed during the year will sufficiently indicate the extent of the Company's operations, and the direction in which further developments may be confidently anticipated. In my last report I referred to our contract for mains with the London Electric Supply Corporation; this has been extended, and we are still delivering large quantities of high-tension concentric conductors for their system in London. We secured the contract for, and have now completed, the extensive underground electric light system at Exeter, and have at present a similar contract at Brighton. A number of Irish towns have been cabled on our system, and we are carrying out the contract for the electric light mains of a large town in Sweden. Negotiations are well advanced for similar contracts in this country. In general electric lighting work our manufactures have met with increasing favour, and have been in several instances specified for specially difficult conditions, to the exclusion of other systems. In telegraphy, the railway companies continue to employ our various types of telegraph cables, and we have now in hand a contract with the Secretary of State for India. This has been placed with our Company after prolonged tests and experiments by the officers of the Government in India, who have satisfied themselves as to the high value of our insulating material in resisting the deteriorating effects of the heat and moisture of the Indian climate. We are justified in expecting that this contract will be followed by the further application of our cables for electrical work in hot climates where permanent efficiency cannot be secured with rubber or guttapercha. Recent enterprise in telephony has stimulated the manufacturers to special exertions in the production of cable suitable for the transmission of telephonic currents over long distances, and notable advances in this direction have been made within the past few years. Since the organisation of the Company's factory at North Woolwich, this important work has been the subject of constant experiment and investigation, and we are now manufacturing long-distance telephone cables of the highest efficiency. It is satisfactory that the resources of our works, and the perfection of the machinery and appliances, have enabled us already to undertake and successfully to complete large contracts both in this country and abroad for the new type of cable. Notwithstanding the preliminary difficulties which always beset a new industrial undertaking, and the exceptionally keen competition which we have had to meet from the beginning of our business, the constantly growing demand in every branch of electrical engineering, and the high favour with which our manufactures have been received, foreshadow the early success of the Company.

The **Chairman** commenced by moving the adoption of the report and accounts. In doing so, he wished to make a few observations concerning the present position of the Company. They all regretted that no dividend could be declared, but he did not think that any of them were surprised at that, having regard to the fact that the Company was still in its youth, and the difficulties to meet with incidental to all new undertakings. He pointed out the important increase in the Company's business and the improvement in its position since a year ago. During the past year ending Sept. 30, 1892, the increase in the business had been over 20 per cent., and instead of having a loss of £1,500 they had turned that loss into a profit of £482, and that was a profit for the first time. There was, however, more than that. From the 30th September, 1892, to date, there had been an increase in the business of the Company as compared with the same period of the previous year of more than 100 per cent., showing at the present moment that the trade was rapidly developing. The most important point was that the working capital was still insufficient, as had been shown during the current year, when they had had to issue debentures to the extent of £10,000, almost the whole of which had been taken or dealt with by the Directors. It was important to observe, then, that probably still more capital might be required as the business developed, and it was perfectly evident if the shareholders were not disposed to co-operate with the Directors in subscribing that new capital, that additional money must be raised at heavy expense to the shareholders. But the Directors were not disposed to allow the Company to be damaged by not having sufficient working capital. He might remark that

they were all agreed in having entire confidence in the future of the Company if enough capital were provided, and without that capital they could not meet the natural development of the business. He therefore wished to impress upon the shareholders the importance of co-operating with the Directors in furnishing that capital. One reason why they had not shown a greater profit was because they had had to provide a larger plant than the current business required, because they had to be prepared to execute large orders speedily and at any time. They would, therefore, understand that the business required considerable capital, like all well-developed undertakings. He further stated that never since the Company was first founded had he seen such a list of enquiries as at the present moment. He regarded that as a satisfactory feature, without going into details, which ought to help the shareholders in forming their opinion as to the future of the Company, and in furnishing fresh capital. They were there a body of Directors—he was sorry to say almost an entire body of Directors—turned into a committee for a general meeting, but he hoped that those present would communicate the wishes of the Board to the other shareholders. He then moved the adoption of the report and accounts.

Lord Medway seconded the motion.

Mr. Seon observed that he, as he considered was the case with the other shareholders, had expected a dividend, but was surprised that such was not the case. Of course a great many of them did not place their money in a company to have no dividend for three or four years. He had £700 invested in the Company, and the only thing he saw of it was that the market price of the shares had diminished. He asked when they might expect a dividend.

The **Chairman**, in reply, did not wish to pledge his word, but he believed that during the present year they would see something in the way of dividend. He himself had a larger share in the Company than Mr. Seon, and he regretted more than that gentleman that no return had been made, because of his responsibility as a director. He had been told by a friend when the Company was formed that they would make no profit for three years, and he was surprised, but that had been their experience. They had had to work against great difficulties but he believed they were now surmounting them, and he thought the fact that a small profit had been earned was an encouraging feature.

Colonel Wyndham Murray, M.P., confirmed Mr. Seon's remarks about a dividend, and said that at the last meeting it was foreshadowed that there would this year be a dividend to divide. He also directed attention to the fact that when he bought shares at the starting of the Company it was stated that the Company at that time had been realising 24 per cent., and that there was a probability of an increased percentage.

The **Chairman**, in answer, remarked that it was quite true that a dividend had been anticipated this year, and he was as much disappointed as anyone. One great difficulty was their fixed expenses, which in a business of that nature were always very large in proportion to the business, and they had not had the amount of increase in trade anticipated a few years ago. He felt that with the good management which they had they were in a better position. With regard to the statement in the prospectus, that was quite true as far as the capital involved in the business, and he would not be surprised if the statements were fulfilled in years to come. It was far different to pay interest on a small than on a large capital. If they compared their position with that of other electrical companies, he thought they should congratulate themselves, and he believed they were on the eve of better times. He then put the motion.

This was carried without any dissentient.

Mr. George F. Smart was elected a director in the place of Colonel J. T. North and Mr. R. S. Waring, who had ceased to be directors. The retiring Directors, Mr. Wm. Fowler and Mr. G. Fleming, and the auditors, Messrs. Cooper Brothers and Co., were re-elected, and the proceedings came to a close.

GENERAL ELECTRIC POWER AND TRACTION COMPANY, LIMITED.

An informal meeting of the above was held yesterday at Winchester House under the presidency of the Chairman of the Company. As the statement and accounts were not ready, the assembly was adjourned for their preparation and presentation on January 31.

NEW COMPANIES REGISTERED.

Becket, Limited.—Registered by Loughborough and Gedge, 23, Austin-friars, E.C., with a capital of £10,000 in £1 shares. Object: to adopt an agreement, made December 15, between P. Everitt of the one part and H. H. Preece, on behalf of this Company, of the other part; to carry on business as electrical engineers and machinists, brass and iron founders, etc. Registered without articles of association.

W. Pope and Son, Limited.—Registered by H. C. Godfrey, 60, Finsbury-pavement, E.C., with a capital of £12,000 in £10 shares. Object: to adopt and carry into effect an agreement made November 30 between W. W. Pope of the one part and O. Wethered, on behalf of this Company, of the other part; to acquire the business of mechanical and electrical engineers now carried on by W. Pope and Son at Slough, and to develop and extend the same. There shall not be less than two nor more than seven directors, the first being elected by the signatories to the memorandum of association. Qualification, £100. Remuneration to be fixed by the Company in general meeting.

BUSINESS NOTES.

Cardiff.—Tenders will be advertised for shortly.

Diary.—The Brush Electrical Engineering Company sends us a neat pocket diary as a New Year present.

Underground Telephones.—Notice has been given by the St. Helen's Corporation to have in the near future all telephone wires underground.

Elmore's Patent Copper Depositing.—The profit and loss account for the year ended June 30 last shows a loss on working of £8,566. 5s. 6d.

Burnley.—The tenders for wiring of Burnley Town Hall are to be sent in by January 18th, to the borough surveyor, Burnley (specification fee, £1. 1s.).

Hampstead.—A sum of £25,000 is to be borrowed by the Hampstead Vestry for electric lighting when the sanction of the Local Government Board has been secured.

Personal.—Mr. A. Grundy is rejoining Messrs. Baily and Grundy, of Amberley Works, Paddington, as manager of the electrical and contract department, from the New Year.

Commercial Cable Company.—The general offices of the Commercial Cable Company in London have been removed from 18, Bishopsgate-street Within, to Bishopsgate House, 55 and 56, Bishopsgate-street Within, E.C.

Western and Brazilian Telegraph Company.—The receipts for the week ended December 23, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,254.

Zoological Society.—Prof. George Forbes informs us that he has just given the contract for electric lighting of the rooms of the Zoological Society, in Hanover-square, to Messrs. Drake and Gorham, as the result of competitive tenders.

Elmore's Wire Manufacturing.—The report of the Directors states that ample working capital has been provided for, that the works are completed and have been furnished with a large supply of raw copper, and that practical operations have commenced.

Buxton.—At the meeting of the Buxton Local Board on Friday, a report was presented from the committee appointed to enquire respecting cost of electric light for Buxton. After a long discussion it was decided to obtain estimates for a central installation.

City and South London Railway Company.—The receipts for the week ending December 25 were £927, against £871 for the corresponding period of last year, or an increase of £56. The total receipts for 1892 show an increase of £2,127 over those for the corresponding period of 1891.

Halifax.—The Halifax Gas Committee on Friday adopted a resolution recommending the Town Council to take steps for supplying electricity for lighting purposes, under the powers of the Halifax Corporation Electric Lighting Order, 1892, and to advertise for an electrical engineer at the salary of £200 a year.

Pontypool.—At a special meeting of the Pontypool Local Board last week, the clerk reported that he had received the copy of the license of the Pontypool Electric Light and Power Company, Limited, from the Board of Trade, asking for the Board's observations thereon before they granted it. It was decided to consider it in committee.

New Popp Company.—M. Victor Popp has organised a new company under the title of Société Générale d'Eclairage et de Force Motrice, 22, Rue d'Aumale, Paris, with a capital of 400,000f. The company takes the concession until 1907 for lighting the Entrepôts de Bercy, and will exploit compressed air, hydraulic, and electric distribution of power.

Llandudno.—The question of an electric tramway came before the Llandudno Commissioners at their monthly meeting. It was resolved to defer dealing with the matter until next meeting, Mr. Dunphy remarking that he hoped Mr. Kingsland (the promoter of the scheme) would not think there was much chance of getting a tramway along the beach.

Windsor.—The Windsor Electric Lighting Company have completed laying the mains in Peascod-street, High-street, and Thames-street, and the pavements have been replaced. A number of connections have been made with business establishments in each of the three streets, especially in the High-street, and it is expected that before long the light will be in use.

Santiago.—With reference to tenders for Santiago, all proposals will be opened on March 1, 1893, in Santiago, and a deposit certificate to the order of the Municipality of 20,000dol. (Chilian currency) must accompany each tender. The particulars of the tender and the plan of the city of Santiago may be seen at the office of the Chilian Legation, 5, New Burlington-street, W.

Pilsen Electric Company.—We are informed that Messrs. Gwynne and Co., the well-known engineers, of Essex-street Works, Strand, W.C., have acquired the entire business, patents, and rights of the Pilsen Electric Company, which will in future be carried on as Messrs. Gwynne and Co.'s electrical department at their new works, Brooke-street Works, London, E.C., in large and well-equipped premises.

Uxbridge.—At the last meeting of the Uxbridge Local Board of Health a letter was read from the secretaries to the Uxbridge and Hillingdon Gas Consumers' Company, complaining of the electric tell-tale cable being laid in undue proximity to their mains. We can quite understand how humanity desires to keep at a distance from a mad dog, but we cannot quite understand the harm that an electric tell-tale cable would do to a gas main.

Edinburgh.—From our last issue it will be seen that the Edinburgh Town Council had appointed a deputation to enquire into the electric lighting at various places. The deputation have made visits to London, Newcastle, Bradford, Cambridge, and Oxford, and have secured a large amount of information about the stations at these places. The cost of the deputation was £145.

Electrical Power Storage.—An everlasting reminder, in the shape of a blotting-pad, has reached us from the Electric Power Storage Company. This useful desk book contains diary, memorandum, slip, and pad. The company send also a price-list sheet of their central station cells, giving the curve of voltage of their 42 K cell, discharging at 290 amperes for one hour, and at 50 amperes for 10 hours. Every practising electrical engineer should secure the E.P.S. pad.

Scarborough and Brighton.—Apparently semi-official notes in the Scarborough papers comment bitterly on the request of the Brighton authorities for more money for electric light, and congratulate Scarborough on having a nice private company to take all the risk and do all the work. Why was not Bradford and St. Pancras quoted? The time for seeing whether ratepayers have done wisely in giving electric lighting powers to companies will be later, when the wise virgins in the list of towns are giving good light at low price. In large and fashionable towns the risk, under proper management, is little enough and the promise of profit large.

Telephonic Charges.—At the last meeting of the Cleckheaton Chamber of Commerce, a letter was read from the Newport Chamber stating that the Post Office had acquired the whole of the trunk telephone lines of the country, and had given notice to renters that from the 1st of January next the annual rentals would be abolished, and a charge would be substituted for each conversation, according to distance, with monthly settlements. Great surprise was expressed at this letter, as nothing had been heard of the subject in the town. The secretary was directed to make enquiries, as the Chamber were of opinion that the proposed change was highly objectionable.

Edinburgh Tramways.—Among the parliamentary measures issued in view of next session is the Bill promoted by the Corporation of Edinburgh for authority to use cable or electrical power "on the tramways acquired and to be acquired" by them, and to make arrangements "for the purchase by the Magistrates and Council of other tramways," etc. The Bill is divided into 22 sections, which cover some nine pages of print, and the promoters suggest as its short title "The Edinburgh Corporation Tramways Act, 1893." Section 6 provides that, if and whenever the Corporation shall have authority to use cable or electrical power, the Corporation may lay down and maintain works necessary for using such power.

Theatre Lighting.—Messrs. Vaughan and Brown have been busy in the lighting of theatres, having recently installed the Trafalgar-square Theatre with 900 lights distributed throughout the building, including some very handsome fittings. They have also fitted "Sexton's" large horse repository in Holborn, which has been in turn theatre, circus, and music hall. They have also fitted over 1,000 lights at the New Palace Theatre, which opened with such *éclat* a short time since. A brilliant crystal glass basket makes a striking effect in the centre of the auditorium ceiling, and a handsome four-tier electrolier lights the well of the grand marble staircase, and numerous brackets in the Renaissance style, with imitation electric candles, are fitted in other parts of the building. The whole of this work was executed in a very short time under the personal supervision of Mr. G. C. Vaughan, jun., M.I.E.E.

Utilising a Corn Mill.—Messrs. Verity and Sons have installed an interesting electrical plant at Hunton for lighting Cheveney, the residence of Mr. T. D. Eden and Mrs. Alexander. The water-wheel, which a few years ago worked the grindstones of Hunton mill, is now driving a dynamo, the current being sent through an underground cable to Cheveney and the Yalding Vicarage. The institute, boys' brigade drillroom, and Riverside, the residence of Mr. Hennah, are also lighted from the same source. A public ceremony was held at the Cheveney Institute to inaugurate the new light, which was switched on in the presence of a large number of inhabitants. Mr. Coles, engineer to Messrs. Verity, gave an account of the installation, which comprises a storage battery of the capacity for 100 16-c.p. lamps for eight hours. The Rev. D. Lamplugh also addressed the meeting, referring to the many acts of generosity done by Mrs. Alexander and Mr. Eden. The lighting was a great success, and the ceremony was followed by an entertainment.

Bournemouth Pier and Gardens.—The Bournemouth Lighting Committee reported, at the Town Council meeting on Tuesday, that they had considered the surveyor's report upon his examination of the various schemes and tenders submitted in competition for the lighting of the pier and gardens by electric light, in which he recommended that the scheme and tender of Messrs. Goddard, Massey, and Warner, of Nottingham, be accepted. The committee adopted his recommendation, subject to reference to the Council. The committee further recommended that Messrs. Goddard, Massey, and Co. be asked to submit an additional tender for providing 3,000 1-c.p. lamps for illuminating purposes, and for laying on the light to the fountains to be constructed in the gardens. The report was adopted, the chairman of the Lighting Committee (Councillor Moore) remarking that the committee considered the surveyor's report a very clever and exhaustive one, and that if carried out they would get a very satisfactory lighting of the gardens and pier.

Ipswich.—At the meeting of the Ipswich Lighting Committee, upon the minute relating to the Ipswich Electricity Supply Company, the town clerk said he had interviewed the Board of Trade on the subject, and they said the company had no legal standing. There were certain conditions to be complied with before the order was granted, and the company had not complied with the conditions, and the Board of Trade declined to recognise them. Mr. Brand said the town then would be open to any of the companies to make application. This company now ceased to exist. The town clerk said at Taunton the same state of things existed, and the Local Authority there were taking steps to take over the powers and plant of the company. The vice-chairman said it was a great pity the same thing could not be done at Ipswich. Mr. G. F. Josselyn moved that the committee do not desire that any further indulgence be granted to this company, which was agreed to.

Liverpool Polytechnic.—The annual general meeting of the Liverpool Polytechnic Society was held at the Royal Institution, Liverpool, on Monday, the 19th inst., Mr. Thos. L. Miller, A.M.I.C.E., president, in the chair, when the ballot was taken for officers and council for 1893—Dr. Geo. Tate, F.I.C., F.C.S., being unanimously elected president for the ensuing session. The president, Mr. Thos. L. Miller, then delivered his retiring address, the subject selected being "The Transmission of Power to a Distance." In opening the address, the transmission of power by means of shafting was referred to and figures given to show the limits within which it could be economically applied. Wire-rope transmission was then discussed, and examples given of installations on this system at various places on the Continent. Hydraulic transmission was then fully dealt with, its history detailed, and the limits of its application pointed out. Transmission by compressed air was then referred to, the recent advances in the construction of stage compressors described—as an example the installation at Paris on the Popp system was given. Transmission by gas, steam, and hot water were then touched on and the steam distribution plant at New York described. Electrical transmission then followed—the use of continuous, alternating, and rotary current systems being fully dealt with—the address concluding with descriptions of various installations where the different systems of electrical transmission had been adopted.

Barnet.—At a special meeting of the Barnet Local Board, the expenditure which would be incurred in the introduction of the electric light was considered. Prof. Robinson had reported as follows: "With reference to the counsel you propose to take about the estimate, and the amount the Board have to decide shall be expended, I have made a rough calculation and find that with a station in a fairly central position, an outlay of about £10,200 would be required for an installation to serve about 2,000 16-c.p. lamps, installed (or a corresponding amount of current for other purposes) with mains in the following roads: High-street, Market-place, Wood-street, and Union-street. From these arterial mains service mains can be laid to supply current in other roads as the demand arises, for which provision should be made as regards capital. To supply a further number of lights will not involve a corresponding outlay: for instance, a further 1,000 lights could be supplied with an additional expenditure of about £1,300. I have thought it desirable to give you this information so that you may determine, with or without the concurrence of the Board, what amount shall be put in the estimate for the Board of Trade of the capital of the expenditure. I suggest the estimate being framed as follows:

Central station plant	£6,150
Land and buildings	850
Electrical mains	4,500
	£11,500

This outlay would, of course, be incurred by degrees. Please to let me know that these figures are adopted." After considerable discussion, the following resolution was carried unanimously: "That the figures as submitted by Prof. Robinson, together with the plans produced and all necessary particulars, be signed by the clerk and forwarded in due course to the Board of Trade."

Poole and White, Limited.—The meetings of the creditors and shareholders of this Company were held on the 22nd in London before Mr. Warley, Assistant Official Receiver. The Company was formed to acquire the business of electrical engineers previously carried on by Messrs. Poole and White in London, branch offices being subsequently opened at other parts, including one at Manchester. The chairman remarked that, according to the statement made to the Official Receiver, there was a surplus (after payment of debenture-holders and preferred claims) sufficient to provide 20s. in the pound for the creditors. He understood that some scheme was under consideration by which that result might be brought about. Mr. John Tryan (solicitor and director) explained to the meeting the past and present condition of the Company, and that the inability to pay the debts arose from the fact that the purchases had been too large. The death of the Duke of Clarence, and the consequent stagnation of business in London, greatly reduced the sales, to which fact he partly attributed the difficulties of the Company. He expressed his belief, however, that the business was inherently sound, and, with additional capital and judicious administration, might be made a success. Mr. Street (Ward, Perks, and M'Kay) appeared on behalf of the International Okonite Company, and said it was the opinion of influential creditors that an independent liquidator and a committee of inspection should be appointed to investigate the books, with a view to arriving at a scheme for either a reconstruction of the old company or the

the company, and eventually, upon an appeal which the company made to the decision of an arbitrator, the Court of Queen's Bench informed them that they could not go behind the company's accounts except for a period of one year. The result of these proceedings, however, was to reduce the price of gas to 3s., at which figure it had remained since 1887. At the time of the passing of the Electric Lighting Act of 1882 the attention of the Council was directed to the privileges corporations had of becoming the distributors of this new illuminant. They had suffered from the experience of three companies in their town — the tramway company, the water works company, and the gas light company — who broke up their roads for the purpose of making the necessary repairs, and left them in a very unsatisfactory condition, and he for one was strongly opposed to another company being allowed to come into the town. From the first inception of the scheme to the sealing of the contract with the Brush Electric Light Company, not a single hand had been held up in the Council against these proposals. They were all aware that the electric light was an acknowledged success. Three years ago the Bradford Corporation decided to have an installation, for which they borrowed a sum of £45,000. The capacity of that installation was only equal to the one they proposed to adopt, at half the cost, and during the last 12 months the sale of current amounted to £6,600. The working expenses were £3,028, and they carried to net revenue account £3,715. 2s. 9d. Of that sum £1,074 was transferred to the sinking fund, and £1,255 for the repayment of principal and interest, leaving a balance of net profits of £1,385. With regard to the street lighting of Hanley, he would point out that they had in the limited area 53 gas lamps at present in use. Last year the cost to the Council was £300. 19s. 9d. Under their electric lighting scheme they proposed to replace those lamps with 20 arc lights, or 30 smaller lights, which could be supplied for £304. With regard to their public buildings, they had in use at the Free Library 107 lights, which last year cost £126 for gas. Less than two years ago the reading-room was painted, but it was now in a very dirty state, and really wanted redoing. He believed that in this respect considerable economy would be saved by the introduction of the electric light. The Corporation felt that they should not allow a private company to come into the town, but that the profits should be applied for the benefit of the ratepayers or the consumers. The standard fixed by the order was not to exceed 8d. per unit, but they hoped to supply the light at 6d. per unit. Mr. W. Tunnicliff, Alderman Shirley (chairman of the General Purposes Committee), and Mr. Edmund Jones also supported the application. Mr. H. Palmer said a great deal of what had been said was in the air. Hanley contained a working-class population in every sense of the word, and the burden upon their shoulders was already too heavy. Newcastle-on-Tyne had made advantageous terms with two companies for the supply of the electric light, and had thus relieved the town from all expense and risk. Why should not Hanley make similar terms with some company? The Council knew practically nothing of the scheme, and there were at least 14 members on the Council who were opposed to it. He contended that, on the showing of the Brush Electrical Company, the cost of the 20 arc lamps would be £512 No canvass of the town had been made with the view of ascertaining to what extent electricity would be consumed. A great deal had also been said as to the improvement and beneficial results which would be derived from the introduction of the electric light to their manufactories, but—General Crozier: I have had some experience of the factories so lighted, and nothing you can say will induce me to believe that gas in a workshop is better than electric light.—There were very few large residential houses in the town, and he failed to see where the light would be consumed except in the few streets confined within the compulsory area. Councillor Granville said the rates were at present 5s. 9d. in the pound, and considering the heavy indebtedness of the borough he strongly opposed any further expenditure. General Crozier: You assume that there will be a loss by the introduction of the electric light. Mr. Granville: I do. I fear the risk of a heavy charge being made upon the rates. Councillors Ball and Pickin also opposed. Mr. Geipel said a statement had been made to the effect that 1d. per unit of electric light was equivalent to 1s. per 1,000 cubic feet of gas. That was a computation which his company made some five years ago, when the incandescent lamp was not so efficient as it was at present. The manufacture of the lamps was a monopoly enjoyed by one firm only, but at the end of 1893 the patent would expire, and competition would make them cheaper. Some companies were able to supply the light at 4½d. per unit, and yet make a profit of 5 per cent. General Crozier said experience showed that at the end of two or three years the electric light was practically self-supporting, but what he wanted to know was whether, in the meantime, they would have to levy an additional rate, and, if so, how much? He had no figures as to the number of persons who would be likely to consume the light. The Mayor said he had been frequently urged by shopkeepers not to allow the matter to be delayed any longer, and Alderman Cooke said it was perfectly certain that if one shopkeeper had an installation the remainder would follow. Messrs. John Whitehead, John Rawson, Samuel Hodson, Charles Edwards and Councillor Schofield also opposed the application on behalf of working-men. They contended that the borough was in a state of bankruptcy, and that their fellow working-men were severe sufferers through scarcity of work and the heavy rates, which they were not in a position to pay. It was also urged that a canvass of the town should be taken with a view of ascertaining the views of the inhabitants in the matter. The enquiry, which lasted over four hours, was then concluded with a vote of thanks to the inspector.

PROVISIONAL PATENTS, 1892.

DECEMBER 14.

23023. **An improved system of telephonic news transmitter.** Theodor Puskas, 45, Southampton-buildings, Chancery-lane, London.

23039. **Improvements in electrical connections or means for supplying current to electric motors.** Wilhelm von Winkler and Julius Fekl, 47, Lincoln's-inn-fields, London.

DECEMBER 15.

23051. **Improvements in galvanic dry cells.** Edward Albert Mitchell and George Thomas Tugwell, 3, Penmartin-road, Brockley, Kent.

23054 **Improvements in medical and other electric induction coils.** Joseph Walker Davis, The Cedars, Tettenhall-road, Wolverhampton.

23057. **Improvements in fittings for use in electric light installations.** Frederick King and William Phillips Mendham, Western Electrical Works, St. Peter, Bristol.

23061. **Improvements in or connected with portable electric lamp fittings.** Wilson Henry Sturge, 12, Cherry-street, Birmingham.

23068. **Improvements in mechanical and electrical interlocking of railway signals, signal or other levers, and block telegraph instruments, commonly called lock and block.** Alexander Ross, Thomas Wharmby, and Robert Stuart Hampson, 17, St. Ann's-square, Manchester.

23086. **Improved arrangement for communicating by telephone between several stations.** Robert Daniel Smillie, 154, St. Vincent-street, Glasgow. (Complete specification.)

23101. **New primary batteries.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Wheatstone House, Heslop road, Balham, London.

23113. **Apparatus for determining differences between the phases of two electric alternating currents of like number of alternations.** Michael von Dolivo-Dobrowolsky, and the Co. Allgemeine Elektricitäts Gesellschaft, 47, Lincoln's-inn-fields, London. (Complete specification.)

DECEMBER 16.

23158. **Improvements in electrical meters.** Paris Eugene Singer, 6, Victoria-road, Kensington, London.

23159. **Electro-mechanical depth indicator.** Arthur R. G. Beal, Longford House, Holyhead, North Wales.

23185. **Improvements in and connected with alarm clocks and electric sound signalling appliances.** Walter Fielder and Henry Newmarch, 166, Fleet-street, London.

23218. **An electric mechanism or device for operating valves.** Jacob Wagner, 1, Quality court, Chancery-lane, London.

23231. **Method of effecting in electric incandescent lamps an airtight union between entering wires made of non-precious metal, and the glass globe.** Paul Scharf, 28, Southampton-buildings, Chancery-lane, London.

23232. **Improvements in and relating to secondary or storage batteries.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (August Marie Michel, France.) (Complete specification.)

DECEMBER 17.

23269. **Varying price electric supply meter.** John Perry, Michael Birt Field, and Louis John Steele, 31, Brunswick-square, London.

23290. **Improvements in alternate-current motors for single and polyphase electric currents.** Engelbert Arnold, 28, Southampton-buildings, Chancery-lane, London.

23295. **An improved centrifugal device for opening or closing an electric circuit.** Sir David Lionel Salomons, Bart., Broomhill, Tunbridge Wells.

23314. **The automatic electric fire alarum.** Elizabeth Fanny Cox, 44, Thornton road, Thornton Heath, Surrey.
